Thermal death time tubes were made by sealing off one end of an 8-in. section of 8-mm. soft glass tubing. After the open end of these tubes were plugged with cotton, the tubes were sterilized in the autoclave. Into each of these tubes 1 ml. of the cell suspension was pipetted aseptically, and the open end of the tube was then sealed. The tubes were held at room temperature for 15 minutes and then immersed in an oil bath at 80 C plus or minus 0.5 C. At 5, 10, 15, 20, 30, and 60 minutes tubes of the test organisms were removed from the bath. The tubes were opened aseptically and the cell suspension poured into a Petri dish and mixed with nutrient agar. Plates were incubated for 96 hours at 28 C and observed for growth.

The results are shown in table 2. It can be seen that no. 52 survived for 60 minutes at 80 C, while 63 survived for more than 60 minutes at 80 C. The other two cultures did not survive the shortest time interval tested. It thus appears that two of the four isolates tested can be considered heat resistant.

COMMENT

Of the 415 samples taken, 14 were shown to contain viable organisms. All samples were obtained from packages labeled "contents sterile until package is opened." In terms of rolls, 12 out of 85, or 14.2%, were contaminated. It should be emphasized again that all precautions were taken to prevent extraneous organisms from entering the bottles of sterile medium. None of the control bottles (85 in all), which were handled in the same manner as the bottles inoculated with samples, gave positive results. If the positive samples were the result of air contamination of the medium, one would expect at least a few of the controls to show the presence of viable organisms. The conclusion is forced that the cotton itself was the source of the bacteria.

TABLE 2.—*Heat Resistance of Bacterial Contaminants Isolated from Market Cotton*

Organism	Description	Plate Count	Survival Time
49	Gram-negative, short rod	630,000,000	Less than 5 min.
52	Gram-positive cocci	6,100,000	More than 30 min., less than 60 min.
58	Gram-positive rod	85,000,000	Less than 5 min.
63	Gram-negative, short rod; spore former	2,100,000	More than 60 min.

The processing temperatures of the different producers undoubtedly vary. However, we have no information available as to the times and temperatures used. The one producer who did volunteer the information was using times and temperatures that should kill all types or organisms. However, the cotton fibers are very poor conductors of heat and as such may give protection to an organism easily killed under ordinary conditions.

These findings indicate that there should be a more stringent control program on the part of both the producers and the Food and Drug Administration in the case of "sterile" market cotton. That viable organisms were found at all different levels in the roll of cotton suggests, also, the need for a rigorous investigation into the heat insulation protection afforded to bacterial life at the center of cotton, gauze, or even a hospital surgical pack. Such studies have been made on canned foodstuffs and have, in many ways, revolutionized the food-processing industry.

SUMMARY

Market cotton labeled "sterile" was found to contain viable micro-organisms. Thermal death time studies on certain of the contaminating organisms indicated that in some cases heat resistant forms were present, while other organisms were heat sensitive and must have survived the sterilization process as a result of the protective effect of the cotton fibers or because of understerilization of the product. In view of the results obtained, it is concluded that the present control program is not adequate to assure the consumer of the sterility of each package of market cotton.

HORMONAL MANAGEMENT OF HEREDITARY HEMORRHAGIC TELANGIECTASIA

Henry J. Koch Jr., M.D., George C. Escher, M.D.
and
John S. Lewis, M.D., New York

The purpose of this paper is to report a new method [illegible] reducing the tendency to hemorrhage in patients with [illegible]editary hemorrhagic telangiectasia (Osler-Rendu dis[illegible]se). Although the periods of observation of the patients treated were of short duration, the longest having been just over one year, the results to date of writing were of sufficient interest to merit a preliminary report.

DEFINITION

The term hereditary hemorrhagic telangiectasia was first advocated by Hanes [1] in 1909. He defined this disease as a "hereditary affection manifesting itself in localized dilatations of the capillaries and venules forming distinct groups of telangiectases which occur upon the skin of the face, nasal and buccal mucous membranes, and give rise to profuse hemorrhage either spontaneously or as a result of trauma." The cardinal findings for the establishment of the diagnosis of this disease are contained in Hanes' definition: (1) the hereditary tendency toward the disease, (2) the presence of typically distributed telangiectatic areas, and (3) the tendency for the telangiectatic areas to bleed. Although the hereditary factor is usually elicited from the patient's history, Fitz-Hugh [2] was the first to call attention to certain patients with no characteristic family history. He explained this on the basis of atavism or "skipped generations" in the inheritance of this disease.

The telangiectases may occur on any of the mucous membranes or anywhere on the external surface of the body. The nasal mucous membrane is oftenest affected, with tongue, palate, lips, buccal area, gum, pharynx, and conjunctiva following in order of disease incidence. The larynx, colon, lung, stomach, liver, bladder, and brain are also affected, but owing to their relative inaccessibility the reported incidence may be less than that actually occurring. On the skin the lesions are found on the face, trunk, arms, finger tips, and nail beds. Aneurysm of the pulmonary artery has been reported by Rundles,[3] but the relation of vascular anomalies to this disease is uncertain. No evidence for a blood dyscrasia except that associated

with chronic blood loss has been noted. The telangiectases begin as dilatations of the capillaries and have a bright red color. As these areas increase in size, the venules participate in the ectasia, giving the cutaneous lesions a violaceous color. The telangiectases of the mucous membranes are always a brilliant red. According to Hanes,[1] the papillae of the corium are obliterated, with loss of the undulations of the stratum germinativum. Immediately subjacent to the attenuated epidermis are wide blood spaces lined by a single layer of endothelium and without either an elastic or a muscular coat.

CLINICAL SUMMARY

The commonest symptom of the disease is epistaxis, but other mucous membranes or the skin may be the exclusive sites of hemorrhage. Hematemeses, hemoptyses, melena, hematuria, and cerebrovascular accidents may occur. Anemia often results from the long-continued blood loss, and fatal hemorrhages have occurred. Trauma is not the only cause of bleeding, for it may occur spontaneously or may arise from irritation or congestion. The telangiectases usually do not appear before the age of puberty. In the third and fourth decades of life they become more numerous and more subject to hemorrhage.

Treatment of this condition has been well summarized by Peluse.[4] Medical management has largely been directed to the control of frequent severe epistaxes. The measures used include the application of caustic agents to the nasal mucosa, submucosal injections of sclerosing solutions such as quinine, ethyl carbamate, and sodium psylliate (sylnasol®), or the use of hemostatic yarn or gauze as nasal packing. Surgical amelioration has been directed to the ligation of the external carotid arteries or anterior ethmoidal arteries and to electrocauterization of the nasal septum and turbinates. X-ray therapy and radium applications to the nasal passages have been of no benefit and have often produced atrophic rhinitis and frequently have caused the sloughing of large areas of the nasal septum. General measures include the injection of moccasin snake venom to increase blood coagulability, and, more recently, favorable reports have followed the use of vitamin P (rutin).[4] Change of climate has been advised in an effort to decrease the incidence of acute coryza with associated nasal hemorrhages. Whole blood transfusions and iron replacement therapy have been required constantly to correct the secondary anemia that usually occurs. No single therapeutic agent or surgical approach, or combination of them, has heretofore consistently decreased the incidence or severity of recurrent hemorrhage. Below are presented the case reports of five patients with hereditary hemorrhagic telangiectasia whose tendency to bleed was reduced with estrogen therapy.

REPORT OF CASES

Case 1.—A 44-year-old woman had a familial history of hereditary hemorrhagic telangiectasia. Her epistaxes began just prior to her menarche at the age of 15. For many years thereafter epistaxes occurred during the five days prior to the onset of menstruation, then disappeared on the first day of her menstrual period. Many local therapeutic measures, including electrocautery, sodium morrhuate injections, submucous resection, and radium implantation, were unsuccessful in alleviating her condition. In 1948, when she was 42, roentgen castration was performed in an attempt to control the epistaxes. There was an immediate radiation reaction, characterized by nausea, vomiting, and cramping abdominal pain. No menstrual periods occurred thereafter. Immediately following this artificial menopause, the patient noted an increase in the severity and incidence of the epistaxes. They became completely acyclic in character and remained so until the time of her admission to Memorial Center on Dec. 13, 1950.

On admission, physical examination revealed the typical telangiectases of Osler-Rendu disease distributed over the tongue, mouth, and nasal mucous membranes. The nasal mucosa was edematous, crusted, and relatively avascular (except for the telangiectatic areas). An extensive perforation of the nasal septum from previous surgery and irradiation was noted.

Laboratory studies revealed a hemoglobin level of 8.0 gm. per 100 cc., a red blood cell count of 2,900,000, and a white blood cell count of 9,500 with a normal differential count. The hematocrit was 29%. Reticulocytes were 1.1%; platelets, 397,000. Bleeding time was 1½ minutes; clotting time, 12 minutes; prothrombin time, 17.9 minutes. Urinalysis was within normal limits. A urinary gonadotropic, follicle-stimulating hormone assay was positive for 104 mouse units and negative for 208 mouse units per 24 hours. (This is within the postmenopausal range by the method used.[5])

The patient received 1,000 cc. of whole blood on Dec. 15, 1950, and again on Dec. 18. The next day the hemoglobin level was 11.2 gm. per 100 cc. Because of the history of cyclic epistaxes and the increase in incidence and severity following roentgen castration, a course of orally administered ethinyl estradiol, 0.5 mg. twice daily, was started Dec. 22. A week later an examination of the nasal mucosa revealed a return to normal vascularity, a decrease in edema, and the absence of crusting or bleeding points. Epistaxes disappeared, and the patient became asymptomatic. She was discharged Jan. 5, 1951. Beginning Jan. 12 and continuing for the next week, the patient noted ankle edema and an increase in body weight. On Jan. 18 she was readmitted, and ethinyl estradiol was discontinued. An immediate diuresis occurred, and the patient remained asymptomatic until Jan. 27, when vaginal bleeding occurred. Epistaxes recurred on Feb. 2 and 4. On examination it was noted that the mucous membranes had returned to their pretherapy state. Ethinyl estradiol, 0.25 mg. per day, was given again on Feb. 5. The patient was discharged on March 1, while still receiving the drug, having been asymptomatic since Feb. 10.

Response to treatment continued until Sept. 17, 1951, when, on the advice of her local physician, the patient discontinued estrogen therapy because of low abdominal discomfort plus soreness and swelling of the right breast. The red blood cell count was 4,100,000. Heavy vaginal (estrogen deprivation) bleeding began Sept. 20 and continued through Sept. 23. On Sept. 26 epistaxes began and continued spasmodically for three days. At the first sign of nasal hemorrhage the patient resumed her daily medication of 0.25 mg. of orally administered ethinyl estradiol. Epistaxes disappeared Sept. 30 and have not recurred to the present writing.

Case 2.—A 60-year-old white man was first seen at Memorial Center on May 31, 1951. A history of repeated epistaxes of 25 years' known duration was elicited. His mother, two brothers, a son, and a daughter had all been subject to frequent and severe epistaxes. The mother and one brother died following severe hemorrhage. Three sisters of the patient had no signs or symptoms of this disease. Epistaxes began in the patient at the age of 35. They were mild, spontaneous, and recurrent every few days and were not troublesome until six years prior to his admission to Memorial Center, when they gradually became more frequent and more profuse. Local medical and surgical measures, as well as radium application to the nasal mucosa, were unsuccessful in controlling the hemorrhages.

On admission, physical examination revealed many telangiectases distributed over the face, trunk, upper extremities, tongue, and mouth. There was a large anterior perforation of the nasal septum due to previous radiation therapy. The mucous membrane of the nose was pale and edematous, with small hemorrhagic spots on the turbinates. Laboratory findings showed a hemoglobin level of 10.7 gm. per 100 cc., a red blood cell count of 3,800,000, and 247,000 platelets. The bleeding, clotting, and prothrombin times were within normal limits. A urinary gonadotropin assay was positive for 104 mouse units and negative for 208 mouse units per 24 hours, an abnormally high value for men. The 17-ketosteroids (total neutral fraction) were 9.4 and 8.0 mg. per 24 hours. Blood chemistry studies, including serum chloride, sodium, potassium, total protein, cephalin flocculation, and thymol turbidity tests, were all within normal limits.

[4] Peluse, S.: Gingival Hemorrhage with Oral Manifestations in Hereditary Hemorrhagic Telangiectasia: Successful Control with a Sclerosing Agent Sylnasol: Effect of Vitamin P and Nicotinic Acid: Role in Case Reported Which Was Observed 5 Years, Arch. Otolaryng. 44: 668-685 (Dec.) 1946.

[5] Method of Kleinfelter, Albright, and Griswold in Smith, P. H.; Albright, F., and Dodge, E.: Modifications in Methods for Precipitation and Assay of Increased Amounts of Pituitary Gonadotropic Substances in Urine, J. Lab. & Clin. Med. 28: 1761-1766, 1943.

Administration of ethinyl estradiol, 0.25 mg. daily, was started June 7, 1951. There was no change in the frequency or severity of the patient's epistaxes until June 16, when a severe epistaxis occurred, and the patient was admitted to the University of Pennsylvania Hospital for nasal packing and transfusion. At that time an examination revealed a decrease in the size of the facial telangiectases. There was no change in the nasal mucous membranes.

The patient was readmitted to Memorial Center June 25, at which time the dose of ethinyl estradiol was increased to 0.5 mg. daily. Laboratory studies revealed a hemoglobin level of 12.1 gm. per 100 cc., a red blood cell count of 4,300,000, and a white blood cell count of 9,700 with a normal differential. Liver function studies, including cephalin flocculation, thymol turbidity, total protein, and albumin-globulin ratio, were within normal limits. On June 28 the nasal packing was removed without bleeding. The nasal mucous membranes were pink, glistening, and without evidence of telangiectases. The patient continued to be asymptomatic and was discharged on June 29, 1951, while still receiving therapy. One week later epistaxes recurred, then subsided spontaneously with no further recurrence.

A reexamination Aug. 20 revealed tenderness and swelling of both breasts, with loss of libido. Treatment was therefore changed to orally administered ethinyl estradiol, 0.5 mg. plus 5 mg. of methyltestosterone daily. Breast discomfort disappeared, and libido improved. On Oct. 22 the platelets were 86,000; by Dec. 10, 1951, they had increased to 170,000 without change in medication. The patient has remained asymptomatic to the present writing.

Case 3.—A 47-year-old white woman was admitted to Memorial Center in March, 1951, complaining of frequent epistaxes and melena accompanied by abdominal cramps and weakness. Both her grandmother and mother had telangiectases of the face and finger tips and also frequent episodes of epistaxis. The patient had occasional epistaxes in childhood. Her menarche occurred at 12 years of age. No unusual bleeding episodes were noted during the years of regular cyclic ovarian function. In 1936, when she was 32 years of age, a hysterectomy and bilateral salpingo-oophorectomy were performed for uterine fibroids, following which menopausal symptoms appeared. Shortly after this procedure, facial and thoracic telangiectases developed.

The patient was first seen at Memorial Center in 1939, at which time a diagnosis of Osler-Rendu disease was made and the facial lesions were treated with dry ice. Nasal hemorrhages were not incapacitating until 1947, when very frequent epistaxes developed that were refractory to all medical and surgical measures. In 1949 irregular gastrointestinal bleeding developed. The patient was readmitted to Memorial Center in February, 1951, because of incapacitating nasal and gastrointestinal bleeding. Following discharge, this patient was referred to the experimental hematology section for consideration of estrogen therapy.

On March 7, 1951, physical examination revealed the typical telangiectases of Osler-Rendu disease. They were distributed over the face, trunk, and upper extremities. The nasal mucous membrane was pale, atrophic, and crusted with blood. Examination was, otherwise, noncontributory. Laboratory studies on March 7 revealed a hemoglobin level of 12.3 gm. per 100 cc., a red blood cell count of 4,500,000, and a white blood cell count of 6,300 with a normal differential count. The platelet count was 360,000. The bleeding, clotting, and prothrombin times were within normal limits. A urinary gonadotropin assay on March 30 was positive for 104 mouse units and negative for 208 mouse units, a normal value for a postmenopausal woman.

On March 13, therapy with orally administered ethinyl estradiol, 0.25 mg. daily, was started. Within 10 days after institution of hormone therapy, epistaxes and gastrointestinal bleeding diminished. In one month a distinct reduction in number, size, and erythema of cutaneous telangiectases was evident. In May, 1951, two months after the institution of hormone therapy, a cyclic pattern in treatment response was noted. While receiving orally administered ethinyl estradiol, 0.25 mg. daily, the patient was in comparatively good health for three weeks. With no change in dosage, spontaneous diuresis occurred, followed in a few hours by exacerbation of bleeding and increased prominence of the telangiectases. The episode lasted for approximately one week and was followed by a three week period of favorable response. The patient was hospitalized from June 18 through June 27 for a trial period without treatment. There was prompt return of severe bleeding and telangiectases.

In August, 1951, an episode of diuresis recurred. At the same time increased epistaxes and increased prominence of telangiectases were noted. The dose of ethinyl estradiol was temporarily increased to 0.25 mg. twice daily, with prompt amelioration of these signs and symptoms. Ethinyl estradiol, 0.25 mg. daily, was resumed and was effective for the subsequent three weeks. The patient has been taught to recognize this cyclic change in response, and she varies the dosage promptly, with resultant minimal signs and symptoms.

Case 4.—A 53-year-old white man had three or four episodes of epistaxis in childhood. During the 15 years preceding admission the epistaxes had become increasingly severe, with episodes one to three times daily. About 10 years preceding admission he had had radium treatment to the nasal cavity. Since then the nasal hemorrhages had been treated by chemical and electrical cauterizations and, more recently, by ligations of the anterior ethmoidal and external carotid arteries. None of these measures had reduced the bleeding. Most of his hemorrhages occurred at night and were preceded by prodromes of nuchal pain and fulness in the frontal region. No family history of bleeding tendency was elicited.

Physical examination revealed typical stigmas of hereditary hemorrhagic telangiectasia of the face and violaceous lesions of the tongue and hard palate. The nasal mucosa was edematous and pale, with scattered lesions on the septum and turbinates and marked crusting. The heart was enlarged both clinically and roentgenologically, although the lung fields were clear. Abdominal examination revealed a palpable liver edge 2 cm. below the costal margin in the right midclavicular line (though dietary history was adequate and alcoholic intake was denied). Rectal examination revealed a symmetrically enlarged, boggy prostate. Laboratory studies prior to therapy revealed a red blood cell count of 4,200,000, a white blood cell count of 5,300, a platelet count of 256,200, and a hemoglobin level of 11.7 gm. per 100 cc. Bleeding time was 2 minutes; clotting time, 10 minutes; prothrombin time, 16.1 minutes. Liver function studies showed a sulfobromophthalein (bromsulphalein®) sodium retention of 23%, while cephalin flocculation was negative in 24 hours and 1+ in 48 hours. Thymol turbidity was 1.29 units. Total protein was 7.0 gm., with a normal albumin-globulin ratio. Acid phosphatase was 0.2 Bodansky units, and the alkaline phosphatase was 13.6 Bodansky units. Urinary gonadotropin assay was positive for 6.5 and negative for 13 and 52 mouse units per 24 hours. (This is a normal value for the male by this method.[5]) The 17-ketosteroids (total neutral fraction) were 7.4 mg. per 24 hours.

On July 10, 1951, therapy with orally administered ethinyl estradiol, 0.25 mg. daily, was started. There was no change in the incidence or severity of epistaxes during the first two weeks of treatment. During the next two weeks epistaxes gradually diminished in volume and by Aug. 6 had ceased. At that time, however, the patient complained of lassitude, loss of libido, breast tenderness, dyspnea, and ankle edema. Treatment was changed on that date to ethinyl estradiol, 0.5 mg. plus methyltestosterone 5.0 mg. daily. In addition, he was placed on a low salt diet. He was next seen on Aug. 20, by which time breast tenderness, dyspnea, ankle edema, and loss of libido had disappeared. Also, a decrease in the size and number of telangiectases was noted. There was no change in the size of the liver, the edge of which was still palpable 2 cm. below the costal margin.

of ampullary carcinoma have been studied. The serum amylase determination was of value in the diagnosis of carcinoma of the head of the pancreas in three out of four cases (table 3). In two cases there was a significant amylase elevation, while in one there was a significant depression of the amylase titer, compatible with extensive atrophy of the acinar cells, which was confirmed by histiological examination. In cases of carcinoma of the body and tail, serum amylase values proved to be of no diagnostic value. In one case of ampullary carcinoma there was an elevated amylase level (case 10, table 3).

Table 3.—*Serum Amylase Levels in Cases of Carcinoma of the Pancreas and Ampulla of Vater*

	Case No.	Maximum Serum Amylase Level (Mg./100 Cc.)	Comment
Carcinoma of the head	1	1,426	Jaundiced; surgery confirmed diagnosis
	2	959	Jaundiced; autopsy confirmed diagnosis
	3	147	Jaundiced; lesion localized to head without obstruction of pancreatic duct
	4	82	Jaundiced; inoperable
	5	48	Jaundiced; extensive atrophy of pancreas
Carcinoma of the body or tail	6	115	Not jaundiced; confirmed at surgery (body)
	7	206	Not jaundiced; autopsy revealed lesion of tail
	8	100	Not jaundiced; surgery revealed lesion of body
	9	292	Not jaundiced; autopsy revealed lesion of body
Carcinoma of the ampulla of Vater	10	973	Jaundiced; confirmed at surgery
	11	107	Jaundiced; confirmed at surgery
	12	87	Jaundiced; confirmed at surgery

It appears to me, after studying these 12 cases, that serum amylase determinations may be of some diagnostic value in the early detection of neoplasms of the head of the pancreas and of the ampulla of Vater. However, a normal serum amylase level in a patient with obstructive jaundice contributes nothing to the perplexing problem of differentiating between a benign and a malignant lesion as the basis for the obstruction.

Peptic Ulcer.—The intimate anatomic and physiological relationship of the gastroduodenal tract to the pancreas readily explains the elevated amylase levels that are frequently encountered in cases of penetrating and perforated peptic ulcers. In 1934, Hinton [21] suggested that the study of pancreatic enzymes could be of diagnostic value in cases of duodenal ulcers penetrating into the pancreas. A few years later, Probstein and coworkers [6a] reported four cases of peptic ulcer involving the pancreas in which the blood amylase was found to be moderately elevated. Subsequent reports [22] have established the diagnostic value of elevated amylase values in penetrating peptic ulcers.

My interest in the serum amylase value in cases of penetrating peptic ulcer was stimulated by the need for a simple and reliable test to confirm the clinical impression that a previously uncomplicated duodenal ulcer was penetrating into the pancreas, as strongly suggested by the change in the character of the pain. Since this study was undertaken, nine cases of penetrating peptic ulcer have been collected in which the serum amylase level was found to be elevated. The clinical diagnosis was confirmed at surgery in six of these cases. In a fairly large number of controls (uncomplicated, active peptic ulcer) serum amylase values consistently were found to be within normal limits.

Acute gastroduodenal perforation, without pancreatic involvement, occurring within a few hours after a meal, is frequently associated with an elevated amylase level.[23] This was demonstrated by Pemberton [6c] in his experimental work on dogs. The source of this elevated serum amylase appears to be the pancreatic amylase, which has spilled from the intestine into the peritoneum and reabsorbed into the circulation. My experience with serum amylase values in cases of duodenal perforations is very meager. One such case was studied in which an erroneous diagnosis of acute hemorrhagic pancreatitis was made on the basis of a serum amylase level of 2,000 mg. per 100 cc. Postmortem examination revealed a duodenal perforation with bile peritonitis, with a normal pancreas grossly and microscopically. The common bile duct and pancreatic duct were patent and free from calculi.

Diseases of the Salivary Glands.—It has been conclusively demonstrated that disease of the salivary glands, especially mumps, are associated with elevated serum amylase levels.[24] Such cases rarely present diagnostic problems, and the elevated serum amylase is of interest only because of its source. A few cases of mumps were studied, and in all there were elevated serum amylase levels, ranging from 578 mg. to 950 mg. per 100 cc. These elevations usually reached a maximum concentration by the fourth day of the illness. It was of interest to note that none of the patients with elevated amylase levels had abdominal symptoms.

Renal Disease.—One of the mechanisms that partakes in the "regulation" of the normal amylase level of the serum is renal excretion of amylase. When renal function is impaired, there is retention of amylase in the blood as reflected by elevated values, along with diminished excretion by the kidneys.[25] The level of serum amylase in cases of renal insufficiency seldom reaches the elevations seen in acute pancreatic lesions. My experience in a small number of cases of renal disease with azotemia has shown the serum amylase to be moderately elevated, ranging between 370 and 480 mg. per 100 cc. It was of interest

to note in these cases that as the serum amylase rose there was a parallel rise in the blood urea nitrogen.

Adequate evaluation of moderate elevations of serum amylase requires consideration of the status of renal function. The temporary impairment of renal function frequently encountered in acute hemorrhagic pancreatitis does not alter the significance of the elevated value, for in this acute disease the amylase values are well over 1000 mg. per 100 cc. In cases of chronic renal insufficiency, the serum amylase value usually is under 500 mg. per 100 cc. and rarely poses any problem in the interpretation of this moderate elevation.

* Jaundiced.

Diseases of the Hepatobiliary Tract.—In view of the varied reports [26] on the significance of serum amylase values in cases of hepatic disease, bile duct calculi, cholecystitis, and cholelithiasis, it seemed desirable to evaluate the diagnostic value of serum amylase determination in such conditions.

Liver Disease: Comfort [26a] found normal values for serum amylase in 22 cases of hepatic disease. Gray and co-workers [26c] reported that impaired hepatic function due to liver disease of various types is usually associated with a subnormal level. It seems difficult to offer a valid explanation for a subnormal amylase level in cases of liver disease, unless severe pancreatic insufficiency, either functional or organic, is concomitantly present.

Thirteen cases of liver disease were studied, and my observations are of interest only in that they confirmed the impression that serum amylase levels are within normal limits in cases of disease of the liver. In all cases there was normal pancreatic function as determined by function tests. The serum amylase values observed in this small series of cases of liver disease are expressed in table 5. The serum amylase levels seen in these cases did not confirm the belief that liver disease is associated with low or subnormal amylase values.

Cholecystic Disease: Cholecystic disease is also considered to be associated with a subnormal or low amylase value. This appears most unlikely; if any deviation from normal is to be found, one would anticipate an elevation in light of the frequent associated cholecystic disease in cases of acute and chronic recurrent pancreatitis. Normal serum amylase values were obtained in four cases of obstructive jaundice due to common duct calculi and in two cases of common duct stricture secondary to surgical intervention. One patient (E. J., table 6) with a common duct calculus had a serum amylase level of 333 mg. per 100 cc.; the pancreas was reported by the surgeon to have a "normal" appearance.

Twenty-eight patients with cholecystic disease had repeated serum amylase determinations while in the hospital for a painful attack. The significant serum amylase values obtained are shown in table 6. The clinical diagnosis was confirmed at surgery in 24 cases and by postmortem examination in one case. Clinical and roentgenologic evidence established the diagnosis in the remaining three cases. Serum amylase values in all but one case (E. J.), were within normal limits; the lowest value obtained was 64 mg. per 100 cc.

The amylase values obtained in these 28 cases do not reflect any tendency toward "subnormal" values as is generally believed to be found in cholecystic diseases. However, I am of the opinion that serum amylase determinations in patients with known cholecystic disease and repeated episodes of acute painful seizures may be of diagnostic value in the detection of recurrent pancreatitis. Frequently, the diagnosis of chronic recurrent pancreatitis is missed, and in these cases the condition is usually mistaken for some form of biliary tract disease.

to such patients. The mechanism for this is the resulting spasm of the sphincter of Oddi induced by administration of morphine or codeine.[27] I have had no opportunity to study the serum amylase response in patients with biliary dyskinesia, but I have seen one patient with biliary tract disease in which spasm of the sphincter of Oddi apparently was induced by meperidine (demerol®) hydrochloride resulting in a significant rise in serum amylase (714 mg. per 100 cc.). When meperidine was not given, subsequent serum amylase values remained within normal limits. At this hospital, we do not administer morphine and allied compounds to patients undergoing serum amylase determinations, especially to those patients with abdominal pain and suspected biliary tract and/or pancreatic disease.

SUMMARY AND CONCLUSIONS

The usefulness and importance of serum amylase determination in acute pancreatic lesions has had clinical recognition since Elman's tremendous contribution to this field. Despite the diagnostic value of serum amylase in pancreatic disease, this simple informative test is frequently not utilized.

Significant elevations of serum amylase occur within a matter of hours in cases of acute pancreatitis, and maximum concentrations are observed within 12 to 24 hours. There appears to be no constant relationship between the height of the amylase level and the severity of the attack; however, it appears that serial serum amylase determinations furnish invaluable information as to the activity and duration of the acute process in the pancreas. The serum amylase test has proved to be invaluable in cases of chronic recurrent pancreatitis. Twenty-five cases of chronic recurrent pancreatitis with hyperamylasemia during an acute exacerbation were collected and are reported in this communication.

The diagnostic value of the serum amylase test in cases of carcinoma of the pancreas and ampulla of Vater was determined in a small series. It was found to be of some value in cases of carcinoma of the head and of the ampulla. In cases of carcinoma of the body and tail, serum amylase levels were of normal value, as one would anticipate in view of their location and the uninvolvement of the main pancreatic duct.

Certain types of gastroduodenal lesions are associated with elevated serum amylase levels, especially in cases of duodenal perforations without pancreatic involvement. One such case was studied and is herein reported. Penetrating peptic ulcers frequently involve the pancreas and are readily diagnosed clinically on the basis of the moderate elevations in serum amylase. Nine such cases were collected and are included in this report. Other clinical conditions associated with elevated serum amylase values are diseases of the salivary glands and renal insufficiency. From the observation of elevated serum amylase levels in these conditions one readily realizes that elevated amylase values are not pathognomonic of primary pancreatic disease. However, critical evaluation of the clinical findings, along with the height of amylase elevation, will enhance the usefulness of the serum amylase test and not detract from its diagnostic value.

The previous belief that liver disease and cholecystic disease are associated with "low" or "subnormal" serum amylase levels could not be confirmed. Serum amylase determinations in the cases herein reported almost consistently revealed values within normal limits.

I am of the opinion that significant elevations reflect a pathological increase of either pancreatic amylase or salivary ptyalin because of disease of the pancreas or salivary gland. The elevated values encountered in cases of various abdominal conditions other than primary pancreatic disease are indicative of associated or secondary pancreatitis or excessive absorption of the "exocrine" pancreatic amylase, such as occurs in duodenal perforations. The slight to moderate elevations encountered in cases of renal insufficiency are readily understood.

Serum amylase determinations routinely should be made in all patients with acute abdominal pain. Elevated values in such patients invariably are of diagnostic value when correlated with other clinical findings. Critical evaluation of an elevated serum amylase enhances the diagnostic value of this test.

CHROMIUM INTOXICATION

WITH SPECIAL REFERENCE TO HEPATIC INJURY

Luke R. Pascale, M.D., Sheldon S. Waldstein, M.D., Gertrude Engbring, M.D., Alvin Dubin, M.S.
and
Paul B. Szanto, M.D., Chicago

Although chromium compounds have been known for many years to be toxic to various organs of the body, primary hepatic injury has not been a conspicuous clinical finding. The organs most frequently injured by these agents appear to be those that come in direct contact with them, either by external exposure or by excretion, namely, the skin, the mucous membranes, and the kidneys.

A variety of surface lesions have been ascribed to contact with soluble chromium compounds. As early as 1827, Cumin[1] described the characteristic "chrome hole" lesions. These occur on exposed parts of the skin, especially the hands, and are punched out, deeply penetrating, painless ulcers.[2] Macular erythema, scarlatinoid

---

Dr. C. D. Proctor performed the polarographic determinations of chromium in the urine specimens.

From the Hektoen Institute for Medical Research of the Cook County Hospital and the Department of Medicine, Stritch School of Medicine, Loyola University.

[1] Cumin, W.: Remarks on the Medicinal Properties of Madar, and on the Effects of Bichromate of Potass on the Human Body, Edinburgh M. J. 28:295-302, 1827

and pustular eruptions, and eczematoid lesions of the skin due to contact with these substances have also been reported.[3] Ulceration and perforation of the nasal septum due to inhalation of plating solution fumes have been described frequently.[4] There is little surrounding mucosal inflammation, but there may be pronounced hyperemia. Painless inflammation of the oral mucous membranes, perforating ulcers of the palate, and ulcers of the eyelids, conjunctiva, and cornea also occur.[5] Inhalation of chromium compounds has been implicated in the pathogenesis of certain cases of pneumoconiosis, allergic asthma, and respiratory tract carcinoma.[6] Inflammation of the respiratory tree has been produced in animals by inhalation of chromic acid dust.[7]

Ingestion of chromium compounds, usually potassium bichromate, leads to severe vomiting, thus preventing much absorption. Nevertheless, instances of systemic poisoning due to absorption of chromium from the gastrointestinal tract and even from the skin have been reported in humans and produced in experimental animals.[8] Once absorbed, the compounds are eliminated by the kidneys primarily and in the bile and feces. Experimentally, it has been shown that 60% of a single dose of chromium is eliminated in the urine within the first eight hours.[8g] This would account for the frequency of uremia in cases of acute poisoning.[9] In humans the tubules are the primary site of injury, whereas in animals glomerular as well as tubular damage has been produced.[10] Other regions reported to be injured by chromium are the central nervous and hematopoietic systems.[11] Hepatic abnormalities have been reported only occasionally, for the most part in accidental human poisonings due to unusual exposure to chromates or in the experimental intoxication of animals. Hepatomegaly without jaundice was noted in a person poisoned acutely, and fatty livers have been found at autopsy in cases of acute and chronic intoxication.[12] An experimental study of chronic chromium poisoning in rabbits demonstrated liver cell degeneration, inflammatory cell infiltration, Kupffer cell proliferation, and large amounts of chromium in the liver.[8g]

The existence of hepatic injury due to the usual industrial exposure to chromium has not been recognized. Surveys of persons in contact with these compounds, for example, in the electroplating, aircraft, and shipbuilding industries, have emphasized the skin and mucous membrane lesions but have not found clinical evidence of systemic poisoning.[13] Blair [4g] stated, "There is no evidence, from the literature or otherwise, that any injury from contact with chromic acid solution or spray in chromium plating develops into a constitutional disease."

We recently had the occasion to study an employee of a chromium plating plant, who had been admitted to the Cook County Hospital because of jaundice. Urinary chromium excretion was found, and the results of hepatic tests and findings on liver biopsy were compatible with the diagnosis of acute hepatitis. In an attempt to determine whether there is a relation between industrial exposure to chromium and liver injury, eight fellow workers were screened; in four, significant urinary chromium excretion was found. The four were studied by a series of hepatic tests and, but for one, by needle biopsy of the liver. Because of the widespread industrial use of chromium at present, these cases are reported to call attention to the possibility of liver injury due to subtle intoxication with these compounds.

METHODS

Twenty-four hour urine specimens were digested with nitric and sulfuric acids and evaporated to dryness. The residue was quantitatively analyzed for chromium, as chromate, by polarography.[14] The hepatic tests performed are listed in tables 1 and 3. Liver biopsy was performed by use of the Vim-Silverman needle. The tissue was fixed in formaldehyde solution, and sections were stained with hematoxylin-eosin, aniline blue, trichrome, iron, hemofuchsin, and silver stains.

REPORT OF CASES

CASE 1.—A. J., a 36-year-old Negro woman, was admitted to Cook County Hospital on Feb. 9, 1951. She had been employed in a chromium plating factory continuously for five years, working next to a chromic acid bath. For the past year she experienced intermittent abdominal swelling. Three weeks prior to admission, she noted pruritus and anorexia, which became increasingly severe. Two weeks later icterus appeared, and the stools became lighter and the urine darker in color. These symptoms persisted until admission. There was no history of alcoholism or exposure to other known toxins.

She was well developed physically, in no apparent discomfort, and afebrile. The skin was excoriated mildly, especially over the back. The scleras were moderately icteric. A few lymph nodes were palpable in the neck, axillas, and groin. The nasal mucosa was intact. The lungs and cardiovascular system were normal. The level of the abdomen was 2 cm. above the xiphopubic line. Neither liver nor spleen was palpable, and ascites was not demonstrable.

Urinalysis revealed a specific gravity of 1.025, no albumin or sugar, 2+ bilirubin, and 2+ urobilinogen. Within two days bilirubin was absent from the urine and urobilinogen excretion increased to 4+; by the 16th day, the latter had returned to nor-

* Normal values in our laboratory are given in parentheses.

† de la Huerga, J., and Popper, H.: Estimation of Serum Gamma Globulin Concentration by Turbidimetry, J. Lab. & Clin. Med. 35: 459-465 (March) 1950.

The hospital course was one of gradual improvement, with disappearance of visible icterus in 16 days. Twice the patient had episodes of abdominal distention, vague abdominal discomfort, and headache, which lasted 24 to 48 hours and subsided without therapy other than analgesics. X-ray of the abdomen showed moderate amounts of gas in the large bowel during these episodes. Initial gastrointestinal x-rays showed findings suggestive of irritable colon, which later disappeared. The gallbladder was normal.

The results of the hepatic tests are tabulated in table 1. Initially the icterus index was 95 units, the thymol turbidity 20.8 units, and the cephalin-cholesterol flocculation 2+ (later 4+). Serum globulin, especially the gamma fraction, was moderately elevated. Serial determinations showed gradual return toward normal. Five weeks after admission sulfobromophthalein retention was 30%. Qualitative examination of the 24-hour urine on the fourth hospital day was strongly positive for chromium. Subsequent quantitative analyses of 24-hour urine specimens, before and after the use of dimercaprol injection, are recorded in table 2.

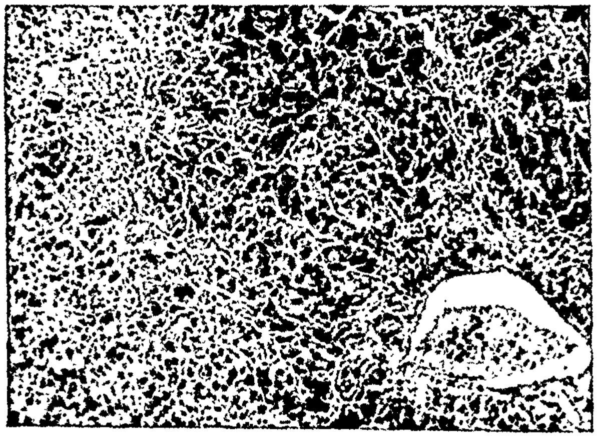

Fig. 1 (case 1).—There is marked centrolobular necrosis and Kupffer cell proliferation. The enlarged portal field is infiltrated with lymphoid and histiocytic cells and shows moderate bile duct proliferation. (× 120)

Biopsy of the liver was performed on the eighth hospital day. Histologically, there was necrosis of the liver cells of the central zone with dilatation of the sinusoids. The few liver cells preserved in the zone had eosinophilic cytoplasm, and the nuclei were markedly pyknotic or absent. The Kupffer cells were increased in number and size. There were focal accumulations of lymphoid type cells within the sinusoids or in place of liver cells. Bile pigment was noted chiefly in liver cells in the central zone, but occasionally elsewhere. The portal fields were moderately enlarged and showed lymphocytic and histiocytic infiltration and a moderate degree of mature bile duct and capillary proliferation. No fat was seen (fig. 1 and 2).

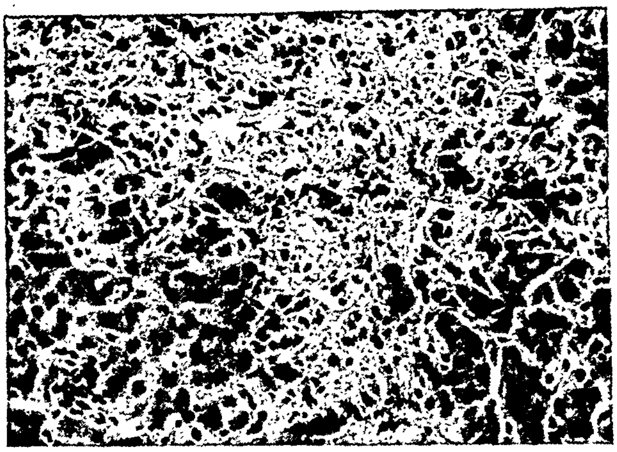

Fig. 2 (case 1).—There is necrosis of the liver cells in the center of the lobule. The cells that remain show variation in size and in nuclear and cytoplasmic staining. Marked proliferation of Kupffer cells and focal accumulations of lymphoid and histiocytic cells can be seen. (× 240)

14. Proctor, C. D.: To be published.

CASE 2.—J. R., a 28-year-old Negro, worked next to a chromium plating tank for four years. For the past year he noticed a metallic taste in his mouth. Six months previously nasal ulcers developed, which were successfully treated with petrolatum applications. There was no history of alcoholism or exposure to other known toxins. Abnormal physical findings included injection of the nasal and pharyngeal mucosa and tenderness over the area of liver dulness. Urinalysis, hemogram, chest x-ray, and gallbladder visualization gave normal results. The results of the hepatic tests and quantitative analyses of the urine for chromium are recorded in tables 2 and 3. Prior to liver biopsy, the prothrombin activity was 65% of normal. After 40 mg. of synthetic vitamin K was given parenterally, no significant change in prothrombin activity occurred.

Microscopically, the liver cells around the central vein contained pyknotic nuclei and a smudgy, or homogeneous, eosinophilic cytoplasm. Elsewhere, the nuclei showed moderate pleomorphism, and the cytoplasm contained fat and hydropic vacuoles. A moderate amount of bile pigment was found in the liver cells. The Kupffer cells were slightly increased in number, and scattered focal necroses were seen. The portal fields were enlarged and very cellular, and moderate capillary, bile duct, and fibroblast proliferations were noted (fig. 3).

CASE 3.—A. L. J., a 31-year-old Negro, worked in the chromium plating industry for four years. For the past two years he periodically noted soreness and redness of the nasal mucosa and had muscular aches. There was no history of alcoholism or exposure to other known toxins. There was injection of the nasal mucosa. The results of the remainder of the physical examination, as well as the urinalysis, hemogram, chest x-ray, and barium enema, were normal. The results of the hepatic tests and quantitative examination of the urine for chromium are recorded in tables 2 and 3. In the section a few of the liver cells about the central vein contained fine, granular bile pigment, and an occasional focal necrosis was noted. Otherwise, the liver was normal.

CASE 4.—C. R., a 27-year-old Negro, worked in a chromium plant for one year, periodically at the chromic acid bath. He had an epistaxis one month before examination but was otherwise symptom free. Except for hyperemia of the nasal mucosa, physical findings were normal. The results of urinalysis, hemogram, chest x-ray, and gallbladder visualization were normal. The results of the hepatic tests and the quantitative examination of the urine for chromium are recorded in tables 2 and 3.

Morphologically, the cells immediately around the central veins showed smudginess and eosinophilia of the cytoplasm, pyknotic nuclei, and occasional karyorrhexis. The Kupffer cells were increased in number and often increased in size. There were foci of lymphocytes within the sinusoids and occasionally in place of liver cells. The portal fields were small and contained a slight amount of lymphocytic infiltration. A few liver cells contained granular or diffuse bile pigment.

CASE 5.—R. E. J., a 22-year-old Negro was removed from the plating to the mechanic section after six months of employment because of the development of nasal ulcers. He had no subsequent symptoms. The results of the hepatic tests and analyses of the urine are recorded in tables 2 and 3. Liver biopsy was not done in this case.

COMMENT

Because of their protein-precipitating and oxidizing properties, chromium trioxide, chromates, and bichromates are potent protoplasmic poisons. Chromic oxide, trivalent chromium salts, and metallic chromium are much less toxic.[15] Chromium has been reported to be present in the teeth but has not been found in other tissues normally.[16] In intoxications, however, it has been found widely distributed in most organs and secretions, and its appearance in the urine has been reported in several patients.[17] Exposure to these substances is common, because of their widespread use in industries such as printing, tanning, photography, dyeing, and electroplating.[18] In the last process, the metal to be plated with chromium is immersed in a solution of chromic acid, through which is passed an electric current. Owing to the liberation of oxygen and hydrogen gases at the electrodes, a fine spray of chromic acid arises over the bath, carrying chromium trioxide into the air. The maximum safe concentration of chromium trioxide has been considered to be 0.1 mg. per cubic meter of inhaled air. Unless proper ventilation is present, the mist from chromic acid baths may lead to concentration of chromium trioxide of 2.5 to 6.5 mg. per cubic meter of air.[4c]

All our patients worked in a chromium plating plant for one to five years, four of the five patients constantly next to the chromic acid bath. Four had a history or findings, or both, of the commonest type of injury in the chromium plating industry, namely, nasal hyperemia or ulceration. All were eliminating significant amounts of chromium when examined. Two showed clinical evidence of hepatic involvement: A. J. (case 1) was jaundiced, and J. R. (case 2) had definite hepatic tenderness but was otherwise well. The other patients had no physical evidence of systemic disease.

[18] Chromium Poisoning: Cause and Prevention, Industrial Health Series, No. 5, United States Department of Labor, 1943.

Each patient had abnormalities in the results of the hepatic tests. A. J., whose clinical course was one of hepatitis, had grossly abnormal results of hepatic tests initially, followed by gradual improvement. The liver biopsy showed centrolobular necrosis, marked Kupffer cell proliferation, enlarged portal fields with lymphocytic and histiocytic infiltration, and bile duct proliferation. J. R., having liver tenderness on physical examination, had diminished prothrombin activity, which did not respond to adequate parenteral administration of vitamin K; a borderline elevation of the icterus index; and abnormal retention of sulfobromophthalein. Here, the findings on biopsy were focal necroses, moderately increased cellularity of the portal spaces, moderate damage of the cells around the central veins, and bile pigment imbibition. A. L. J. (case 3) had an elevated icterus index, reduced cholesterol ester percentage, and abnormal retention of sulfobromophthalein. In this instance the only abnormal finding on microscopic examination of the liver was the finely granular bile pigment imbibition. C. R. (case 4) had an elevated icterus index on one occasion (normal on another), elevated serum globulins, and abnormal retention of sulfobromophthalein. The biopsy showed minimal central degenerative changes combined with bile pigment imbibition. R. E. J. (case 5), most removed from the chromic acid bath and found to be eliminating the least amount of chromium, had borderline retention of sulfobromophthalein as the only abnormal result of the hepatic tests. Biopsy was not done in this case.

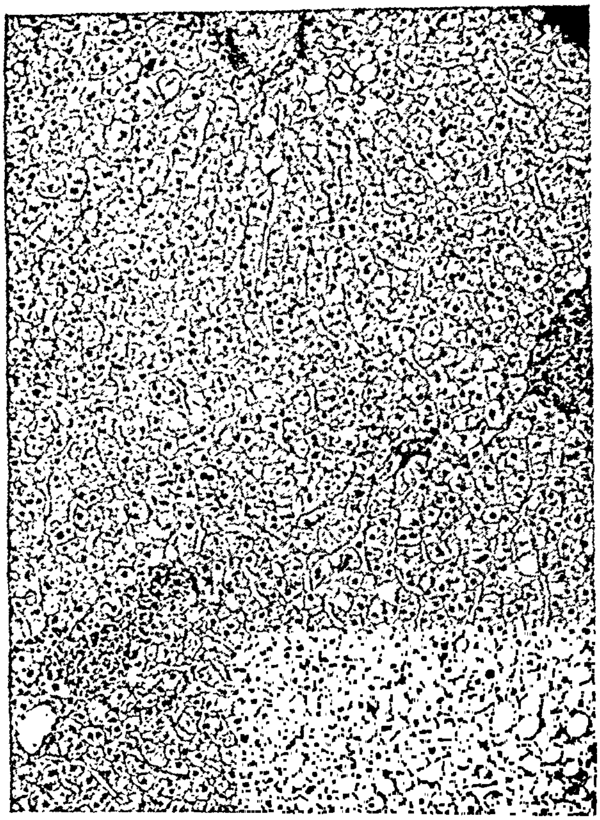

Fig. 3 (case 2).—The cells around the central vein show alterations in nuclear and cytoplasmic staining. Scattered fat and hydropic vacuoles are seen. The portal fields are enlarged and very cellular. (× 125)

Of the four biopsies, two showed pronounced and two slight abnormalities of hepatic structure. The histological changes found in the patient in whom jaundice developed were strikingly similar to those observed in experimental chromium poisoning in rabbits.[6g]

The indictment of chromium in these cases as the causative hepatotoxin seems justified in view of the history of exposure to a toxic form of chromium (chromium trioxide from chromic acid mist), the absence of exposure to other toxins (including alcohol), the finding of chromium in the urine in significant amounts, abnormalities in the results of hepatic tests, and the fact that the pathological findings in the liver did not resemble those seen in viral or other infective hepatitis, but rather those seen in the so-called toxic hepatitis.[19]

If it be true that industrial exposure to the toxic chromium compounds may cause systemic as well as surface injury in the human, the health hazard in plants using these compounds is not as negligible as suggested in the literature. Prophylactic measures, such as adequate ventilation and protective covering, should be taken in all factories to reduce exposure to a minimum. Skin and mucous membrane lesions should be treated promptly to prevent chronic systemic absorption of these compounds.[20] The effect of dimercaprol injection could not be evaluated in our patient because she was recovering at the time it was used.

The clinical well-being of most of our patients despite the presence of hepatic dysfunction as evidenced by hepatic tests and biopsy suggests that similar cases may have been overlooked because of the lack of more recent techniques for hepatic examination. The incidence of systemic poisoning in industries using chromium compounds, therefore, may require further investigation.

SUMMARY

Acute hepatitis with jaundice was observed in a person employed in the chromium electroplating industry. Chromium was identified in the urine on several examinations. Liver biopsy showed histological changes resembling those found in "toxic" hepatitis. In four other electroplating workers, found to be excreting significant amounts of chromium in the urine, hepatic tests and liver biopsy showed mild to moderate abnormalities. These workers had no symptoms related to the liver or other internal organs but did have the nasal lesions frequently attributed to chromium intoxication. The appearance of hepatitis in a chromium worker, as well as the existence of hepatic dysfunction in workers with no constitutional complaints, suggests that subtle systemic intoxication of employees of industries using chromium may be a definite health hazard.

CLINICAL NOTES

FATAL VENTRICULAR FIBRILLATION FOLLOWING PROCAINE AMIDE HYDROCHLORIDE THERAPY

REPORT OF A CASE

John M. Read, M.D., Elko, Nev.

This is a report of death immediately following an intravenous injection of procaine amide ("pronestyl") hydrochloride. The case is reported because it is felt that instances of important untoward as well as the favorable effects of a drug should be generally known. Except for deaths in moribund patients and/or following exceedingly large, rapidly administered doses [1] no instances of death following the routine, cautious use of procaine amide have come to my attention. Aside from an increasingly cautious tone in the more recent articles [2] and an isolated report of agranulocytosis following oral administration,[3] most authors have mentioned the relative lack of serious toxic effects.[4]

REPORT OF A CASE

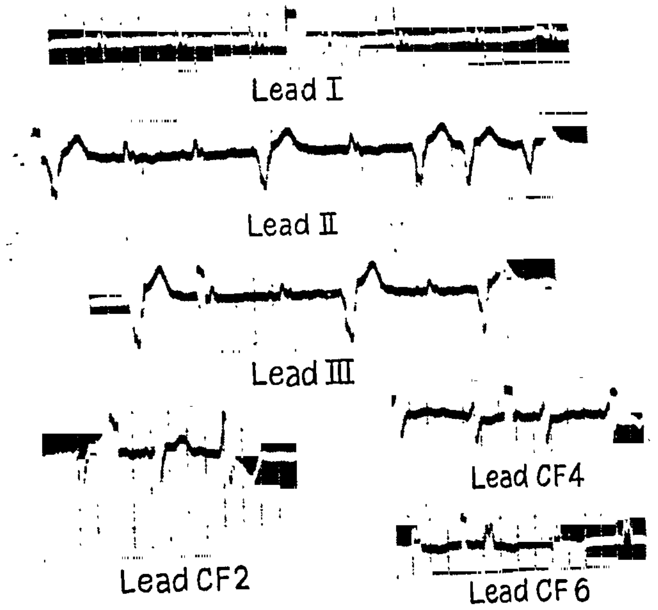
A 61-year-old widow was admitted to the Elko General Hospital in June, 1951, after a third attack of acute weakness and dyspnea in 48 hours. She had had rheumatic fever at 11 years. In 1935 she was admitted to the Elko General Hospital and a diagnosis of mitral stenosis and congestive failure was made. Since then she had been admitted to several hospitals in the Western states and had taken digitalis preparations irregularly. Prior to this recent admission she had taken no digitalis for one week. For the past several years she had noted an irregular "jumpy" heart from time to time but had noted no lasting spells.

On admission she appeared tired. The temperature and respirations were normal. A slight, but definite, malar flush was present. The ocular fundi were normal, and the neck veins not distended. The lungs showed only a few scattered rales at both bases posteriorly. The apex beat was palpable in the sixth intercostal space at the anterior axillary line, and the area of cardiac dulness corresponded to this. The second pulmonic sound was accentuated, and the loud apical first sound was preceded by a rumbing murmur. A harsh, grade 3 systolic murmur was heard over the precordium. The blood pressure was 120/80. An occasional premature beat was heard. A slightly tender, smooth liver edge descended 3 cm. below the right costal margin. There was no sacral edema. ankle edema present, graded as 1+. There was

The blood cell count, urine, sedimentation rate, and stool were normal. The result of the test with VDRL antigen was negative. The chest roentgenogram showed hazy, diffuse densities extending from both hili and a greatly enlarged heart with a typical "mitral" configuration. The electrocardiogram showed slurred ventricular complexes and diphasic T waves in the limb leads. The QRS time was 0.14 seconds. The R-T segment was slightly elevated in CF_1, CF_2, and CF_3 and slightly depressed with inverted or diphasic T waves in CF_4, CF_5, and CF_6. Successive, rapid premature beats, apparently arising in the right ventricle, were present (see the accompanying figure).

On the second day the patient complained of a smothering feeling, palpitation, and heaviness in the chest. That evening the nurse noted the pulse rate to be 130 and called the patient's physician. When seen at 11:30 p. m., she was apprehensive, cold, and orthopneic. She complained of palpitation, which she believed to have been present since 9 a. m. (14 hours). The neck veins were engorged. The apical and radial rates were equal and varied between 162 and 164. There was marked variation in the intensity of the first sound as heard over the apex and precordium, but the rhythm seemed regular. The blood pressure was 110/74. Carotid sinus pressure was not applied.

In the light of the bedside findings and the recent electrocardiographic observations, it was felt that ventricular tachycardia was present. Because of the patient's condition, prompt treatment seemed imperative. Accordingly 200 mg. (2 cc.) of procaine amide hydrochloride was given slowly into the left antecubital vein. The injection required three minutes, and a stethescope was held in place over the precordium during and after the injection. The rate and rhythm remained unchanged until just after the needle was withdrawn, when, for a few cycles, the rhythm became irregular; then the rate abruptly rose and no count could be made. At this time the patient uttered a faint cry and ceased breathing for a moment. The heart continued to beat wildly and very rapidly for 15 to 20 seconds; then the intensity of the heart sounds diminished and became inaudible. Slow, irregular respirations continued for two and a half minutes after the cessation of heart sounds.



Electrocardiogram taken 36 hours before death.

COMMENT

The close temporal relationship between the administration of the drug and sudden death was so striking as to exclude the possibility of coincidental death from an inevitable ventricular fibrillation. Though electrocardiographic and blood pressure controls were lacking, there seems little doubt that death was due to ventricular fibrillation. The remainder of the bottle was sent to the manufacturer's laboratory; the contents were reported as procaine amide hydrochloride without impurities.

Knowledge of the pharmacology of procaine amide hydrochloride is far from complete, but one may theorize on possible causes for this fatal outcome. The hypotensive effect of intravenous procaine amide has been well described.[5] Death in this instance from such a cause seems highly improbable.

Another known effect is the widening of the QRS complex, and, in some instances, bundle branch block has developed. Recently McCord and Taguchi [2b] noted an increase in ventricular rate when procaine amide hydrochloride was administered to patients with auricular fibrillation. Such quinidine-like effects [6] might more easily cause ventricular fibrillation in a heart in which bundle branch block was already established. Caution in the use of quinidine in the presence of bundle branch block has been advised for years, but in practice this is honored more in the breach than the observance. It may be that such will be the case with procaine amide hydrochloride.

SUMMARY

A case of ventricular fibrillation with death immediately following an intravenous injection of procaine amide is reported. It is emphasized that caution is necessary in the use of this drug; increased caution is suggested in cases of bundle branch block.

VENTRICULAR ACCELERATION FOLLOWING PROCAINE AMIDE HYDROCHLORIDE THERAPY

John L. Denney, M.D.
Harold Miller, M.D.
George C. Griffith, M.D.
and
Morris H. Nathanson†, M.D., Los Angeles

Procaine amide ("pronestyl") hydrochloride has been recently introduced for the treatment of cardiac arrhythmias; its use has been found effective especially in rhythms of ventricular origin.[1] The drug appears to be relatively innocuous, and, aside from occasional mild to moderate hypotensive reactions, no serious untoward effects have been observed. It is known that cardiac depressant and antifibrillatory drugs, although effective in the elimination of ectopic rhythms, may at times induce ectopic ventricular rhythms, including ventricular fibrillation. Such cardiac effects have been observed during the course of quinidine sulfate therapy.[2] They have been observed with greater frequency after the administration of the potent antifibrillatory drug alpha-fagarine and related compounds.[3] In 55 patients with various auricular and ventricular arrhythmias, continuous electrocardiograms were made during and after the intravenous administration of procaine amide hydrochloride.[1d] We found no indication of drug-induced ectopic ventricular activity in this group. However, in three patients with complete heart block the intravenous administration of relatively small doses of procaine amide hydrochloride was followed by the appearance of frequent multifocal ectopic ventricular beats in two cases and a transient ventricular fibrillation in one.[4] It has been suggested that ectopic ventricular activity and ventricular fibrillation induced by quinidine sulfate therapy depends on an impaired function of the conducting system. The following report concerns a patient in whom pronounced widening of the QRS wave and a paroxysm of ventricular acceleration developed during and after the intravenous administration of procaine amide hydrochloride.

REPORT OF A CASE

The patient was a 69-year-old white woman, admitted to the hospital on Nov. 6, 1951. Her complaints were weakness, shortness of breath, and palpitation. She had had a myocardial infarction two years previously and had made an uneventful recovery. Since that time she had had dyspnea on mild effort. On the evening of admission, while walking to the grocery store, she experienced a sudden onset of palpitation, associated with weakness and shortness of breath, and was taken to the hospital.

On admission, she showed the following significant physical changes. She was moderately dyspneic, and there was a slight degree of cyanosis of the lips and finger tips. There was a pronounced distention of both jugular veins. Moist rales were present at both lung bases posteriorly. On auscultation, the heart rate was very rapid but appeared to be regular. The sounds were distant, and there were no murmurs. The blood pressure was 90 systolic and 70 diastolic. The abdomen was obese, but there were no palpable organs or masses. There was no edema of the extremities. The diagnosis was ectopic tachycardia and acute coronary occlusion as a possible basis for the arrhythmia.

An electrocardiogram was made shortly after admission, which showed a ventricular tachycardia, rate 210 per minute (*A* in the accompanying figure). The QRS wave was 0.1 second in duration, and there was a slurring of the R wave on the descending limb. Procaine amide hydrochloride, 500 mg., was injected by vein slowly at the approximate rate of 100 mg. per minute. This was followed by a gradual widening of the QRS; at one minute after the onset of injection, the QRS was 0.14 second and a notching appeared on the descending limb of the R wave (*D* in the accompanying figure). As the injection of the drug was continued, there was a gradual reduction in heart rate and a widening and increased notching of the QRS (*E* through *K* in the figure. Strip *K* taken four and a half minutes after the start of the injection, shows the rate reduced from 210 to 160 per minute and the QRS wave widened to 0.2 second with pronounced notching on the descending limb. Five minutes after the start of the injection of the drug, a series of rapid regular ventricular oscillations appeared (*L* in the figure). There was a gradual reduction in the amplitude of these oscillations. This type of complex may be considered to represent a ventricular tachycardia from a new focus or a ventricular flutter. Such oscillations have been observed preceding the irregular oscillations of smaller amplitude, which are characteristic of ventricular fibrillation.[5] This was followed by ventricular complexes of approximately normal configuration, rate 140, a nodal rhythm (*M* in the figure). Auricular waves preceding the QRS gradually appeared, and restoration of sinus rhythm occurred eight minutes after the start of the injection (*P* in the figure). The patient was given 500 mg. of procaine amide hydrochloride every four hours. She had no further attacks, and subsequent observation showed no evidence of myocardial infarction.

---

COMMENT

Widening of the QRS wave has been observed during quinidine sulfate therapy and is considered as an indication for discontinuance of the use of the drug. Gold [2b] described a case of fatal syncope during the administration of quinidine sulfate, presumably due to cardiac standstill or ventricular fibrillation. An electrocardiogram taken after 5 gm. of the drug had been administered showed that the QRS, which had been normal before treatment, was prolonged to 0.16 second. In discussing the treatment of ventricular tachycardia, Gold stated that it is not wise to continue quinidine sulfate therapy if the QRS has been prolonged to 50% above the control. He expressed the belief that a widening of the QRS may represent a precursor to ventricular fibrillation. Sokolow,[2d] in a recent review, stated that he did not continue quinidine sulfate therapy after the increase in QRS time exceeded 50% of the control value and he used particular caution when the increase exceeded 25%. Kayden and co-workers [1b] noted that continuous intravenous infusion of procaine amide hydrochloride until death in the experimental animal produced the following events: prolongation of the P-R interval, widening of QRS complexes, wandering pacemaker, nodal and ventricular premature contractions, and ventricular tachycardia and fibrillation.

Electrocardiographic changes during the intravenous administration of 500 mg. of procaine amide hydrochloride to a patient with ventricular tachycardia.

Davis and Sprague [6] and Davis [7] have emphasized the significance of the integrity of the conducting tissue in the prevention of ectopic ventricular rhythms. An intact conducting system distributes impulses quickly and uniformly to all regions of the ventricular myocardium. This not only insures harmony of contraction but further produces a uniform state of refractoriness. Such a generalized state of refractoriness protects against reentrant excitation. When there is impairment of ventricular conduction, the stimulus is delayed to portions of the heart and subsequently there is a variable state of refractoriness in the ventricular myocardium. The stimulus may then be blocked at hypoexcitable areas, continue along responsive paths, and reenter the blocked portion when it becomes responsive. This re-entry mechanism is considered to be the basis for ventricular rhythms, including ventricular fibrillation. For this reason it has been emphasized that, during the administration of such drugs as *quinidine sulfate and digitalis, conduction defects* are a warning sign of the onset of serious ventricular rhythms. In the present instance, the ventricular arrhythmia that occurred during the treatment was of short duration and had no untoward effects. However, it represents a prefibrillation state such as is frequently seen before the onset of fatal ventricular fibrillation. It would appear that, as with quinidine sulfate, widening of the QRS during procaine amide hydrochloride therapy is an indication for discontinuance of the use of the drug.

CONCLUSION

A case of ventricular tachycardia treated with procaine amide ("pronestyl") hydrochloride is reported in which the following events occurred: (*a*) progressive and pronounced widening and notching of the QRS wave of the electrocardiogram, (*b*) a short paroxysm of ventricular acceleration of a prefibrillation type, and (*c*) restoration of sinus rhythm. It is suggested that, as with quinidine *sulfate therapy*, a widening of the QRS wave during the administration of procaine amide hydrochloride may represent a precursor to ventricular fibrillation and is an indication for discontinuance of the use of the drug.

1200 N. State St. (Dr. Miller).

Basal Metabolic Rate.—Either hypothyroidism or hyperthyroidism may be present in the face of a basal metabolic rate that falls within the normal range. Moreover, a low basal metabolic rate does not always indicate hypothyroidism, but may represent hypometabolism without hypothyroidism. Contrariwise, an elevated basal metabolic rate does not invariably mean hyperthyroidism. In the absence of thyrotoxicosis high values may be encountered in such diverse states as Paget's disease, polycythemia, anemia, leukemia, lymphosarcoma, Hodgkin's disease, essential hypertension, aortic stenosis, coarctation of the aorta, and dyspnea due to cardiac or pulmonary disease. Elevations of the basal metabolic rate may also result when the patient is inadequately rested or fasted, overexcited, or has a tremor or a punctured tympanic membrane.—J. L. Gabrilove, M.D., and W. R. Dorrance, M.D., Tests of Endocrine Function. *The Medical Clinics of North America*, May, 1952.

FEVER DUE TO PROCAINE AMIDE HYDROCHLORIDE THERAPY

Augustus C. P. Bakos, M.D.
and
John Martin Askey, M.D., Los Angeles

Procaine amide ("pronestyl") hydrochloride is a drug widely used for the elimination and prevention of ectopic ventricular rhythms. Its oral use at times is maintained for long periods to prevent recurrent premature beats or paroxysmal ventricular tachycardia. Toxic side-effects have been infrequent and usually not serious. Minor toxic affects have been gastrointestinal irritation with anorexia, nausea, and vomiting, usually occurring with a high dosage (6.0 to 8.0 gm. a day).[1]

A major toxic effect has been the production of granulocytopenia following bone marrow depression with death.[2] We recently observed a patient in whom chills, fever, generalized muscle pains, malaise, dermatitis, and mental depression developed during the administration of the drug. The fever disappeared abruptly when use of the drug was discontinued and recurred on two subsequent occasions after readministration of the drug. The causative relation of the drug to the fever seemed definite. We had not previously encountered a similar instance, but, during the preparation of this report, we found an article by Leibowitz [3] describing a patient in whom chills and fever developed after oral ingestion of procaine amide hydrochloride. He predicted, "As experience with procaine amide increases it is likely that similar reactions will be encountered." In our patient, much laboratory work was done in an attempt to explain the cryptogenic fever before the drug was suspected as causative. It is probable that other instances are occurring and are unrecognized, especially if the patient is ambulatory and not under close observation. Chills, fever, muscle aches, and malaise could easily be ascribed to current viral infections or other plausible causes. Procaine amide hydrochloride must be suspected as a possible cause of any febrile reaction occurring during its administration.

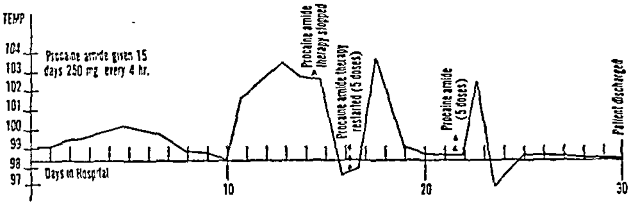
REPORT OF A CASE

A 58-year-old unmarried woman was first seen in the office Jan. 22, 1952, complaining of bilateral anterior chest and shoulder pain, with extension to both arms and to the interscapular region, of six days' duration. An electrocardiogram demonstrated unequivocal evidence of acute posterior myocardial infarction. The patient was immediately hospitalized. Anticoagulant treatment was started, with intravenous administration of heparin and oral administration of bishydroxycoumarin (dicumarol®). Procaine amide hydrochloride, 250 mg. every four hours day and night, was given on admission because of the presence of frequent premature ventricular beats. The patient's temperature on admission was 98.2 F.

During the following 10 days the oral temperature fluctuated diurnally, reaching a high of 100.4 F (see the accompanying figure). This low grade febrile response was accepted as commensurate with cardiac infarction.

On the 11th hospital day, the oral temperature rose to 101.8 F. The patient became nauseated and vomited. She was irritable and apprehensive. During the succeeding four days the temperature remained elevated, reaching a maximum of 104 F. The white blood cell count was 5,000. The cause of the sudden rise in temperature and the clinical picture of malaise, nausea, and vomiting was not clear. Septicemia, genitourinary infection, pulmonary infarction, brucellosis, typhoid, and peripheral thrombophlebitis were considered and investigated with appropriate laboratory studies. After five days of continuous fever, although no one was familiar then with reports of fever due to the use of bishydroxycoumarin or procaine amide hydrochloride, it was thought that the reaction might be caused by one of these.

On the 15th day at 6 a. m., the administration of both bishydroxycoumarin and procaine amide was discontinued. The temperature began to drop and 24 hours later was normal; it remained so during the following 36 hours. Improvement in the patient was immediate and dramatic. The aching and malaise disappeared; the mental irritability and apprehension was succeeded by cheerfulness. The nurses' record said, "She has no complaints." Two days later the procaine amide therapy was started again, 250 mg. every four hours for five doses. The first dose was given at 10 a. m. By 4 o'clock in the afternoon the patient felt distinctly uncomfortable and mentally irritable and by 11 o'clock the temperature was 104 F. The next morning she was nauseated, mentally irritable, and depressed, talking incessantly and wanting to go home. The following day the temperature was normal; she felt much better, appeared normal, and listened with interest to the radio. For five days she felt well and the temperature was normal.



Fever following oral administration of procaine amide hydrochloride. The fever subsided with discontinuance of the use of the drug and recurred when it was readministered on two occasions.

After five days procaine amide therapy was started again. After the third dose the patient recognized the effect of the drug and said, "It is those little yellow pills that are upsetting me." The temperature again rose to 104 F; the next day a maculopapular, itching rash appeared on the extensor surfaces of the arms, feet, thighs, and dorsa of both feet. Again, after discontinuance of the use of the drug, the temperature became normal the next day, and the rash faded. During the remainder of her hospital stay she had no further trouble.

SUMMARY

An instance of fever, chills, rash, and malaise following oral administration of procaine amide ("pronestyl") hydrochloride is reported.

ALLERGY TO PROCAINE AMIDE

Emanuel Hellman, M.D., New York

The therapeutic similarity between procaine amide and quinidine is recognized; however, whereas the toxic effects of quinidine are well known, procaine amide ("pronestyl") has not yet been used widely enough to permit evaluation of its ability to cause toxic reactions. The following case of a true allergic reaction to procaine amide is, therefore, discussed.

REPORT OF A CASE

A 53-year-old man with known hypertension for the past 20 years was first seen on Nov. 11, 1951, with sudden onset of severe substernal oppression. An electrocardiogram revealed acute anteroseptal myocardial infarction. On Dec. 11, 1951, the heart rate, which had been 85 per minute, increased to 115, and numerous extrasystoles, subsequently shown by electrocardiograph to be auricular premature contractions, were noted. The patient was given 1.5 gm. of procaine amide orally; this was followed by 250 mg. every four hours. After the third dose, when a total of 1 gm. had been taken, a generalized maculopapular erythematous rash developed, accompanied by severe itching, congestion of the nose, slight generalized adenopathy, and a fever of 102 F. Cessation of procaine amide therapy and institution of diphenhydramine (benedryl®) hydrochloride, 50 mg. every 4 hours, was followed by complete subsidence of all symptoms within 24 hours.

Inasmuch as the patient was receiving other medication at the time of this reaction, it was decided to test him with procaine amide alone. Consequently, on Feb. 10, 1952, he was placed on 250 mg. of procaine amide every four hours. Following the fourth dose, the identical clinical picture noted above developed; this condition again promptly responded to diphenhydramine hydrochloride. A stained blood smear at the height of the reaction showed 7% eosinophils as compared with ½ to 1% in the control smear before beginning the procaine amide test. A subsequent patch test with the drug was negative.

COMMENT

Hitherto, reported toxic effects of procaine amide had been limited to the circulatory and gastrointestinal systems.[1] Recently, reference has been made to three cases of agranulocytosis [2] and two cases of urticaria [3] following its use. Although it is not unusual to find a patient who is sensitive to quinidine and who has fever and a skin eruption following even small doses, such a reaction to procaine amide has not been previously reported.

HUMAN POISONING BY CHLORDANE

REPORT OF A CASE

Paul Lensky, M.D.
and
Howard L. Evans, M.D., Houston, Texas

The newer insecticides have proved their value in control of insects.[1] Since the products have been made available to the public, however, accidental poisonings have occurred. We are reporting our experience in such a circumstance.

Chlordane, a chlorinated hydrocarbon having the empirical formula $C_{10} H_6 Cl_8$, is in the pure state a viscous, amber-colored, odorless liquid. It can be formulated for use in varying strengths as an oil solution, an emulsion concentrate, a dust, or a wettable powder.[2] Human toxicity of these preparations depends on the type of vehicle as well as the concentration of chlordane. Some of the toxic manifestations ascribed to chlordane preparations may be due to the vehicle alone.[3] Contamination of the skin with certain petroleum distillates has produced anesthesias and paresthesias that may be due to the fat solvent properties of the distillates.[4]

The insecticide enters the body by absorption through the intact skin, by inhalation of dusts or sprays, and by ingestion. Skin and intestinal absorption is enhanced by the presence of fats, oils, or organic solvents.[5] Chlordane is moderately irritating to the skin in concentrated form, but in the diluted solutions commonly used this skin warning fails to appear. As little as 2.4 gm. in solution contacting the skin daily may be dangerous to man.[6] Acute fatal poisoning may result from a dose of 5 to 60 gm.[7] The onset of symptoms may occur as early as 45 minutes following ingestion of chlordane. Death may result within 24 hours, but most commonly not until the third or fourth day. If survival continues to the sixth day, recovery usually follows. Irritability of the central nervous system is the earliest sign and symptom. This irritability progresses into convulsions alternating with periods of depression.[3] Death occurs following deep central nervous system depression with or without a terminal seizure.[7] Chronic poisoning produces predominately inanition, probably due to the severe degenerative changes in the liver, the most severely damaged of the vital organs. These changes are similar to those produced by other chlorinated hydrocarbons such as chloroform.[8] Degenerative changes in the proximal convoluted tubules of the kidney [9] and subserosal hemorrhages in the intestines and heart have been demonstrated in animals.[10]

Prophylaxis should be directed toward preventing acute and chronic exposures to the poison through the skin and respiratory tract in the manufacture, in formulation of commercial compounds, and in the ultimate use by the public. This and a decrease in the accidental ingestion may be brought about by stressing the human toxicity of this substance. Actual treatment involves removal of the poison from the gastroenteric tract and skin as rapidly as possible by any means available. Convulsions should be controlled by sedatives or general anesthesia. Stimulants, and other supportive measures such as oxygen, should be used in the phases of central nervous system depression.

REPORT OF A CASE

C. J. E., 15-month-old daughter of one of the authors, accidentally drank a small amount, probably not more than a mouthful, of a chlordane suspension. This occurred at about 3 p. m. Although the child spit out some of the suspension, the mother promptly induced vomiting by administering sodium bicarbonate solution and gagging the child. This was accomplished within 2 to 3 minutes following ingestion. The chlordane suspension was made using 1 tablespoon of a wettable powder (50% chlordane) suspended in 1 qt. (1 liter) of water. The distributor of the commercial preparation, the county agricultural agent, and a biochemist were consulted. All were of the opinion that the amount taken was probably not toxic, although all admitted there was not sufficient information available to them concerning chlordane's toxicity.

About three hours after ingestion (6 p. m.) a generalized tremor developed, and the child became incoordinate and ataxic, falling several times. Convulsions soon ensued, tonic phases alternating with short clonic phases, until they were controlled by ethyl chloride inhalations about 40 minutes later. On examination when the convulsions began her temperature was 99.6 F rectally, the pupils were dilated but reacted to light, her face was flushed; the respirations were irregular, and the pulse rate was 140 per minute. Risus sardonicus, opisthotonos, bilateral ankle clonus, and generalized hyperactive reflexes were present. Cyanosis was noted only during administration of ethyl chloride. After the convulsions were controlled by ethyl chloride inhalations, amobarbital (amytal®) sodium was given (0.06 gm. intravenously and 0.06 gm. subcutaneously) to facilitate gastric lavage with magnesium sulfate saturated solution. The strong odor of chlordane suspension was apparent in all washings. Some of the magnesium sulfate was left in the stomach. At 7:30 p. m. (4½ hours after ingestion of chlordane) the convulsions seemed controlled, and the patient was admitted to a hospital. Thirty minutes later generalized convulsions recurred and were not controlled until 0.345 gm. of amobarbital sodium was administered intravenously, and 0.06 gm. subcutaneously. Oxygen and fluids intraveneously were given continuously. For the next eight hours respirations were irregular in rate and shallow in depth except for an occasional deep sigh. We were unable to determine whether the respiratory depression was due to the chlordane ingested or to the large amount of amobarbital sodium given. Thirteen hours after chlordane ingestion respirations resumed normal character, and 16 hours after chlordane ingestion the child roused. Examination at this time revealed irritability, dilated pupils, and some ataxia. For the next few hours the child was constantly moving, unaware of her surroundings, and irritable when disturbed. The pupils resumed normal size, and respirations continued to be regular.

During the second day the consulting neurologist found only moderate ataxia and irritability. This irritability prevented the obtaining of an electroencephalogram; however, an electrocardiogram and chest roentgenogram were made, and the patient was discharged from the hospital. The ataxia and irritability progressively diminished and finally disappeared after two to three weeks.

Past History.—The child had had no convulsions previously. She had always been in good health, and her development had been normal.

Laboratory Data.—On the day following admission a blood count revealed only mild hypochromic anemia. On this day and the following day her urine contained an occasional white blood cell and red blood cell in a centrifuged specimen. The electrocardiogram was within normal limits, and chest roentgenogram revealed no abnormality of the heart or lungs. An attempt was made to obtain an electroencephalogram three weeks later but was unsuccessful, owing to lack of cooperation by the patient.

COMMENT

Individual susceptibility to chlordane varies within wide limits, probably even more than is at present determined. In our case the quantity ingested unfortunately could not be determined exactly, but it is our impression that the amount of chlordane ingested by this child weighing 9 kg. did not exceed 100 mg. Because of the individual susceptibility, treatment should be immediate and directed toward the prompt removal of chlordane from the body, no matter how small the amount. Careful gastric lavage in our case was not done immediately because the information we obtained indicated that the amount ingested was too small to be of concern. As Lehman has well stated, "Absolute toxicity of any given insecticide is of relatively minor interest, but the real criterion of utility must ultimately be based on the hazards to man. . . . Little effort is directed towards the study of long-range effects on plant and animal life before the insecticide is introduced into commerce."[11]

SUMMARY

A case of poisoning due to a new popular commercial insecticide, chlordane, demonstrates the signs and symptoms of toxicity. The need for adequate investigation and dissemination of information concerning the dangers of insecticides to man is stressed.

MENINGITIS DUE TO PSEUDOMONAS AERUGINOSA

INTRATHECAL TREATMENT WITH STREPTOKINASE AND STREPTODORNASE AND INTRAMUSCULAR AND INTRATHECAL TREATMENT WITH NEOMYCIN

Vernon Knight, M.D.

Robert C. Hardy, M.D.

and

Juan Negrin Jr., M.D., New York

The over-all mortality from meningeal infection with Pseudomonas aeruginosa was found by Stanley to be 68% in a review of 90 cases reported to 1947.[1] The same author observed that, when the cases were divided into groups depending on whether the infection was primary in the meninges or whether it had developed secondary to foci elsewhere in the body, there was a pronounced difference in the case fatality rate. Patients in whom meningitis was the primary disease, comprised mostly of persons who were infected by lumbar punctures or after neurosurgical procedures, showed a mortality rate of 55%. Patients in whom the meningitis occurred as a complication of infection originating elsewhere in the body showed a mortality rate of 86%. From these data it is apparent that meningitis due to Ps. aeruginosa is a serious disease. Moreover, it is our opinion that published

[1] Stanley, M. M.: Bacillus Pyocyaneus Infections: A Review, Report of Cases, and Discussion of Newer Therapy Including Streptomycin, Am. J. Med. 2: 253, 1947.

reports tend to minimize the mortality figures, since it seems certain that more recoveries than fatalities are deemed worthy of reporting.

Antimicrobial treatment of Ps. aeruginosa meningitis has only occasionally been successful, with the most favorable results obtained by the use of polymyxin B. Tomlin,[2] Hayes,[3] and Jawetz,[4] and their respective associates, have reported the successful treatment of one patient each with this agent. Two of the patients experienced severe local pain at the time the intrathecal injections were administered, and the two who received the material intramuscularly exhibited transient signs of nephrotoxicity, consisting of casts in the urine and albuminuria. Two patients relapsed after initial control of the disease but were later successfully re-treated.

Although this appears to be the most effective antimicrobial agent available for treatment of meningitis due to Ps. aeruginosa, one must maintain some reservations concerning the use of an agent in which the toxic concentration is so close to the therapeutic concentration.

Another approach to the treatment of meningitis that has recently received some clinical appraisal is the intrathecal administration of streptococcic concentrates containing streptokinase and streptodornase. This treatment has proved highly beneficial in cases of empyema and infected hemothorax, and on occasion sterilization of chest cavities has resulted without concomitant antimicrobial therapy.[5] It has been demonstrated that the streptococcic concentrate may cause lysis of purulent and sanguineous exudate,[6] with the result that infecting bacteria may be more directly exposed to host defenses or antimicrobial therapy. Presumably this is the basis for the activity of these substances in meningitis.

Recently we had an opportunity to treat a patient with meningitis due to Ps. aeruginosa that had developed after an elective laminectomy. The treatment employed consisted of intrathecal injections of a solution of streptokinase and streptodornase and intrathecal and intramuscular injection of neomycin. The results were highly favorable, and details of the patient's course constitute the present report.

REPORT OF A CASE

The patient, a 26-year-old white housewife, was first admitted to Bellevue Hospital on Jan. 29, 1951, with a history and physical findings consistent with the presence of a herniated intervertebral lumbar disk. The defect could not be demonstrated by myelogram. On March 14 a right hemilaminectomy of the fifth lumbar vertebra was performed, and a small disk impinging on the nerve root was found. The protruded disk was excised, leaving the dura intact. Twenty-four hours after operation, the patient's temperature rose to 105 F and slight nuchal rigidity was noted. Examination of the wound revealed evidence of infection at its upper end. Separation of the skin margins permitted drainage of approximately 12 cc. of seropurulent material. The infection appeared to arise from the depths of the wound, which was explored down to the dura. No foreign body was found. Cultures of the wound revealed a diphtheroid bacillus, and for this reason penicillin was given intramuscularly in large doses. After five days the patient's temperature returned to normal. On the seventh postoperative day nuchal pain and rigidity were again noticed, and wound cultures at this time revealed Ps. aeruginosa. Despite the presence of this organism, healthy granulations gradually filled the wound, signs and symptoms subsided, and the patient was discharged with the wound virtually healed on May 3. Lumbar puncture was not done postoperatively.

Five days later, on May 8, the patient was readmitted to the hospital, complaining of headache, stiff neck, vomiting, chills, and fever. The operative wound appeared well healed, and there was no local tenderness. Lumbar puncture revealed cloudy xanthochromic fluid, which contained 1,420 white blood cells per cubic millimeter; cultures revealed Ps. aeruginosa. During the next six weeks, the patient received continuous antibiotic therapy in high dosage; penicillin, chloramphenicol, terramycin, and streptomycin were given in various combinations. In the course of the treatment she received three intrathecal injections of streptomycin, 0.05 gm., at two-day intervals. Despite this treatment, she continued to have daily temperature elevations to 101 or 102 F. Cerebrospinal fluid sugar concentrations were low, ranging from 15 to 34 mg. per 100 cc. The chloride level ranged from 80 to 141 mg. per 100 cc., and several protein determinations were approximately 75 mg. per 100 cc. About 1,500 white blood cells per cubic millimeter were consistently observed in the cerebrospinal fluid, and approximately 2,500 red blood cells were noted on several occasions. Several cultures of the cerebrospinal fluid revealed Ps. aeruginosa, and on one occasion this organism appeared in a culture of the blood.

In view of the unremitting infection we decided to explore the wound again. Accordingly, on June 3 a total laminectomy of the fifth lumbar vertebra was done, with exploration of the epidural space. Abscess, foreign body, or other abnormality was not found.

Drug susceptibility tests revealed the organism to be resistant to 25 µg per cubic centimeter of chloramphenicol, aureomycin, and streptomycin. It was found to be sensitive to neomycin (4 units per milliliter in 24 hours). As the patient's condition continued to deteriorate despite three months of intensive antimicrobial therapy, we decided to institute intrathecal treatment with streptococcic concentrate (streptokinase and streptodornase) and neomycin.[7] The patient was given 15,000 units of streptokinase and 3,750 units of streptodornase intrathecally at two-day intervals, with daily intrathecal administration of 5,000 units of neomycin. Neomycin was also given intramuscularly in a daily dose of 120,000 units. The patient continued to receive penicillin. Details of this portion of her course may be seen in the accompanying chart. Her temperature rose to 105.8 F 12 hours after the first intrathecal administration of streptokinase and streptodornase, despite the fact that treatment with corticotropin (ACTH), 75 mg. daily, had been started 24 hours previously. During intrathecal administration of the enzyme solution, and for about one hour thereafter, the patient complained of discomfort of the lower part of the back and saddle area and experienced a dull headache of moderate severity. Lumbar puncture six hours later, however, failed to reveal any significant changes over pretreatment findings. She felt nauseated for several hours. Twenty-four hours after the initial intrathecal medication the patient became semistuporous and disoriented, and there was pronounced increase in nuchal rigidity. The cerebrospinal fluid pressure at this time was 330 mm. of water, and the fluid appeared distinctly more turbid. Great relief followed the slow withdrawal of 25 cc. of cerebrospinal fluid. On the alternate days, in which neomycin was administered intrathecally without enzymes, no subjective discomfort was noted, and there was no temperature elevation or other objective evidence of untoward effect. Cerebrospinal fluid cultures were continuously sterile after the second day of treatment. Chills and temperature elevations to 103 to 105 F occurred 8 to 12 hours after the patient received the remaining two intrathecal injections of streptokinase and streptodornase, and cerebrospinal fluid pressure following the third administration was 520 mm. of water. Sufficient amounts of cerebrospinal fluid were withdrawn to lower the pressure either to normal or to half the initial pressure. Papilledema did not develop. Blood pressure remained fairly constant, while the pulse rate varied proportionately with temperature fluctuations. Urine output was good and remained free of albumin, casts, and blood cells. The plasma nonprotein nitrogen concentration was determined before, during, and after treatment and did not exceed normal limits. Cerebrospinal fluid turbidity rapidly diminished after the completion of treatment, and by the ninth day it was crystal clear. The patient gradually improved; by the time of her discharge, one month after the cessation of treatment, she was without significant abnormal physical signs and had no symptoms. At the time of writing, she had been followed for a period of nine months and had remained well.

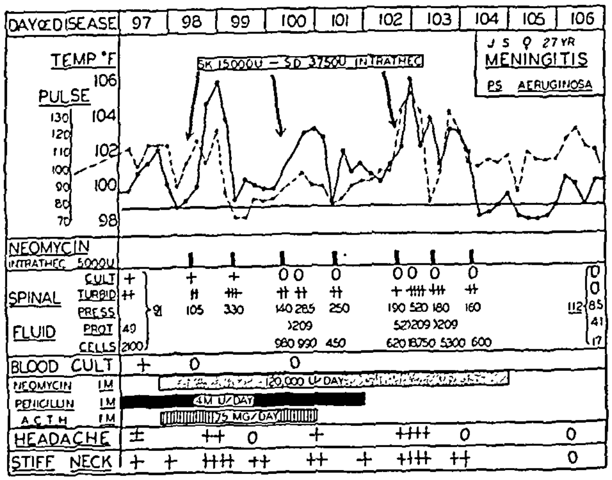
[7] The neomycin used in this study, lot no. 3500424, was supplied by Dr. L. W. Smith, Commercial Solvents Corporation, New York.



Course of patient with meningitis due to Ps. aeruginosa during intrathecal treatment with streptokinase and streptodornase. Neomycin was concomitantly administered both intramuscularly and intrathecally. A severe toxic reaction followed each intrathecal injection of streptokinase and streptodornase, but sterilization of cerebrospinal fluid occurred promptly, followed by complete recovery.

COMMENT

It is difficult to assess the role of the agents used in the successful treatment of the patient. In vitro tests indicated that neomycin was highly active against the strain of Ps. aeruginosa in the cerebrospinal fluid, and its use may have contributed materially to the control of the infection. The effect of treatment with streptokinase and streptodornase is more difficult to evaluate. There are no satisfactory clinical signs or tests by which one can reliably measure the therapeutic effect of these substances in the subarachnoid space. Moreover, the presence or absence of febrile reactions and other evidences of toxicity do not appear to correlate with the therapeutic effect and, in fact, may represent in part chemical irritation by other substances in the streptococcic concentrate. In the evaluation of the treatment of this patient, two further points are worthy of comment. First, the fact that recovery has been reported in three cases in which polymyxin B alone was used (despite two relapses) indicates that antimicrobial therapy alone may be effective. Second, Tillett and his co-workers have reported the recovery of a patient with meningitis due to Ps. aeruginosa following one intrathecal injection of streptokinase.[8] The recovery occurred after several months of failure to cure the patient with intensive antimicrobial therapy (although neomycin or polymyxin B were not given). In this case there was little doubt that the use of streptokinase and streptodornase was responsible for the patient's recovery, whether by permitting exposure of the infecting organism to the previously ineffective antimicrobial agents or by assisting host defenses by lysis of the exudate. The further possibility that the streptococcic concentrates might directly affect Pseudomonas organisms cannot be entirely excluded, but in vitro tests have failed to show inhibitory activity by this substance. Moreover, there was no change of the inhibitory activity of chloramphenicol against a strain of Ps. aeruginosa when streptococcic concentrate was added to the test.[9]

From the case reported by Tillett and his associates, and the one presently under discussion, it appears that intrathecal injection of streptokinase and streptodornase may be of therapeutic value in the treatment of meningitis caused by Ps. aeruginosa.

The toxic reactions in the present case appeared to result from the enzyme therapy, since they occurred after each intrathecal injection and did not occur when neomycin was given alone. In fact, neomycin was well tolerated without apparent evidence of local or systemic toxicity. The chills, high fever, increased cerebrospinal fluid pressure, and lethargy appeared to be referable to a local action of the injected enzyme, and striking relief was obtained by the slow withdrawal of a few cubic centimeters of spinal fluid. The reactions could be explained on the basis of a rapid accumulation of cerebrospinal fluid and increased intracranial pressure after administration of the enzymes.

As has been mentioned previously, the severity of the toxic responses does not appear to be in proportion to the therapeutic effect, and conceivably the reactions could be minimized with further studies of dosage and method of administration of the agent. The toxicity may be serious, however, and in two patients with tuberculous meningitis death occurred a few hours after intrathecal injection of enzyme.[10] At present, a number of other patients with purulent meningitis have received intrathecal enzyme therapy and have tolerated the injections with a minimum of difficulty. The corticotropin was administered in an attempt to minimize the anticipated reaction to therapy, but it apparently had little effect. It does not seem possible to attribute an important role to corticotropin in the treatment of this patient.

The choice of neomycin in the present case was based on knowledge of its in vitro activity against the offending organism. So far as is known there would be no objection to combining treatment with polymyxin B or other antibiotics with intrathecal enzyme therapy. Such a combination might permit shorter periods of treatment with potentially toxic agents and, at the same time, forestall the occurrence of relapses, such as occurred in two of the three patients receiving polymyxin B alone.

SUMMARY

A patient with meningitis due to Pseudomonas aeruginosa, resistant to treatment with several antimicrobial agents, completely recovered after a course of intrathecal treatment with streptokinase and streptodornase and intrathecal and intramuscular treatment with neomycin.

SIMPLE TRACTION DEVICE

E. H. Weissenberg, M.D.
Myron W. C. Grattendick
and
W. Lensing, Jefferson Barracks, Mo.

Recently, we were confronted with the problem of providing a method for mobilization of contractures in both hips and knees of a patient in whom none of the usual orthopedic or physical therapeutic techniques was applicable. The problem was successfully solved with the aid of a simple traction device that was built in a short time without the use of complicated machinery. The purpose of this paper is to make generally available the knowledge of this additional, easily constructed physical therapeutic aid.

The construction of this device is illustrated diagrammatically in figure 1. We used a masonite® board ⅜ in. by 16 in. by 18 in. and two pieces of plywood, each ½ in. by 6 in. by 6 in. The latter were made into two small carriages by attaching four small metal wheels to each. The wheels could spin freely because friction was low. The carriages moved easily with only slight pushing or pulling. Such pushing or pulling force was provided by the weight of the patient's legs while the device was in operation.

REPORT OF A CASE

A 40-year-old white salvage dealer sustained third degree burns while cutting up an old car with an acetylene torch. The gas tank had exploded, and burning gasoline had doused his legs. For nine weeks the patient was treated in various hospitals and at home. When he finally came to the hospital, he had lost 50 lb., and strong flexion contractures in both hips and knees had developed. Passive range of motion in these joints was about 10 degrees; active movements were almost completely lacking. Black leathery eschar covered part of the burned areas on both lower legs and feet. Greenish, purulent discharge came from beneath the fissures. Wet compresses were ordered to prepare the wounds for skin grafting. In the meantime the patient was referred to the department of physical medicine for restoration of normal function of the contracted joints and for strengthening of the severely atrophied muscles of both legs.

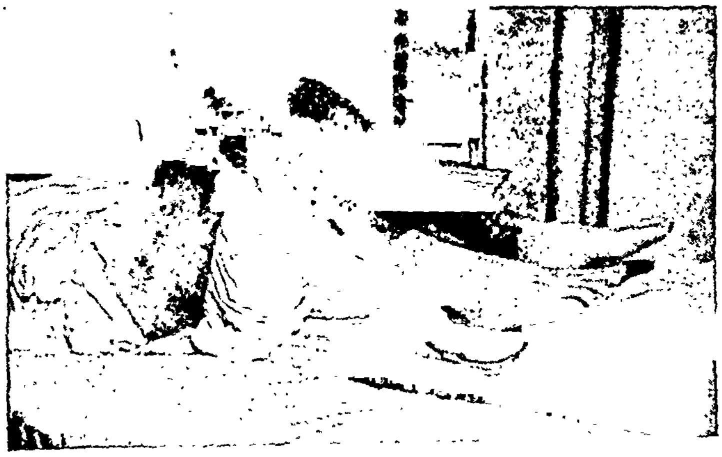

Fig. 2.—Position of patient's legs at beginning of traction therapy.

None of the usual orthopedic or physical therapeutic techniques for mobilization of hip or knee contractures could be used in this case. Adhesive tape traction requires healthy skin, of which the patient did not have enough left; skeletal traction could not be considered, because it would have been necessary to drill the Kirschner wire through denuded and infected skin, which could result in osteomyelitis; passive and assistive motion would have been too paniful, because the legs could not be gripped without including parts of the burned areas; manual traction could not be performed, because what healthy skin was left had become macerated from the wet packs and was too slippery to provide a firm grip. Nevertheless, the joints had to be moved by some method as soon as possible to prevent a seriously crippling condition to result from the contractures.

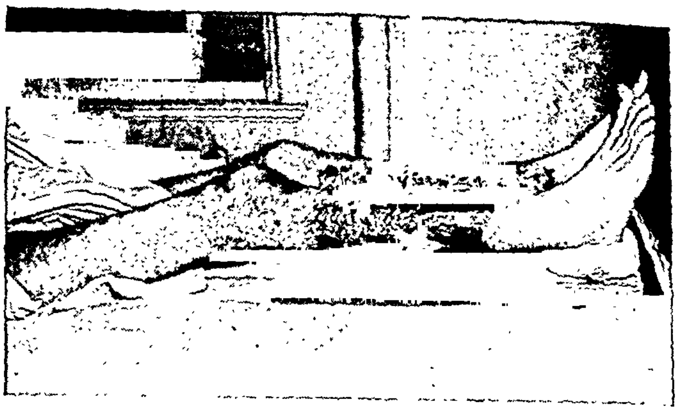

Fig. 3.—Position of patient's legs, with contractures corrected, 24 hours after traction therapy was instituted.

The problem was solved by use of the traction device described. The masonite® board and the two small carriages were put on the bed. Both heels were gently lifted onto gauze "doughnuts" and, with these, onto the carriages (fig. 2). A folded towel was placed under the foot end of the masonite® board to produce an inclined plane, with the foot end of the board higher than the head end. This was necessary because the patient's pain was too severe while the board was in the horizontal position. With the board inclined in the only position the patient could tolerate, it was noted that the carriages had a tendency to roll toward the head, thus increasing the flexion contractures; however, the weight of the legs not only nullified this tendency but even made the carriages move gradually against gravity toward the foot end of the board. It was hoped this would eventually straighten out the contractures. The patient was left in this position, since he did not complain of pain. To the surprise of all concerned, the patient's legs were almost straight after only 24 hours on the traction device (fig. 3). The patient then started active hip and knee exercises, using the device for assistive force as long as his muscles were too weak to perform these movements unassisted. When skin grafting was done, on one leg at a time, exercises were continued on the leg not being surgically treated. Exercises were resumed on the leg that had been operated on as soon as the graft had sufficiently taken. The subsequent hospital course was uneventful.

SUMMARY AND CONCLUSION

Multiple joint contractures were straightened out quickly, yet gently, by the use of a simple traction device. This device also provided assistance to the atrophied muscles for active motion. The same equipment can be used effectively for arthritic patients or postoperatively in cases in which an effective traction device is required. The tractive force is easily regulated by merely changing the incline of the board according to the patient's tolerance. The apparatus is inexpensive and can be improvised without difficulty.

From the Veterans Administration Hospital, Jefferson Barracks, Mo.

Because of space limitations, figure 1 has been omitted from THE JOURNAL and will appear in the authors' reprints.

CONGENITAL THYROID HYPERPLASIA IN TWINS

REPORT OF A CASE FOLLOWING ADMINISTRATION OF THIOURACIL AND IODINE TO MOTHER DURING PREGNANCY

E. B. Saye, M.D.
C. H. Watt, M.D.
J. C. Foushee, M.D.
and
J. J. Palmer, M.D., Thomasville, Ga.

The purpose of this communication is to record the occurrence of hyperplasia of the thyroid in newborn twins following the administration of thiouracil and iodine to the mother during gestation. To our knowledge no other case of apparently induced hyperplasia of the thyroid in humans has been reported. Experimentally hyperplasia of the thyroid has been produced in puppies by thyroidectomy upon the mothers. In regions where endemic goiter prevails, the occurrence of spontaneous congenital enlargement of the thyroid is not rare.

REPORT OF CASE

History.—The first of normally delivered twin girls was stillborn. The mother, aged 36, who had previously borne six healthy children, was receiving treatment for thyrotoxicosis. For five months she had received strong iodine (Lugol's) solution, 10 drops three times daily, and propylthiouracil, 100 mg. four times daily, with amelioration of her symptoms and reduction of the basal metabolic rate from +36 to +11%.

External Examination.—The examination of the stillborn infant began one hour after delivery, Nov. 23, 1951. Permission to open the head was not obtained. Externally the cadaver appeared normal, except that there was a conspicuous smooth tumor, 3 cm. in diameter, at the middle of the neck. The body length (estimated) was 65 cm., the weight 3,000 gm. The entire skin surface was smooth and pink, with no lividity anywhere. There was no rigor mortis. The orifices were empty and without discoloration.

Internal Examination.—The single abnormal finding was the enlarged thyroid, which measured 4.5 by 3.5 by 2.5 cm. and weighed 32 gm. The cut surface was uniform, being slightly reddish, slightly firm, and homogeneous except for slender lobular septums. The lungs were totally unexpanded; the left myocardial wall was contracted. The thymus, the adrenal glands, and all other thoracic, abdominal, and pelvic viscera were normal.

Histological Study.—The sections of the thyroid were uniform and consisted of closely arranged empty follicles separated by loose reticular tissue in which there were numerous capillaries. The follicles varied only moderately in size and were lined by simple cuboidal epithelium, with no parathyroid tissue in any of the sections. There was no demonstrable lesion of the thymus, adrenals, kidneys, liver, pancreas, or spleen. The prenatal atelectasis of the lungs appeared uncomplicated.

The surviving twin sister has an enlarged thyroid but appears normal otherwise.

SUMMARY

The occurrence of congenital hyperplasia of the thyroid, apparently induced, in twins, one of them stillborn, is reported.

From the pathology, surgical, and obstetrical services, John D. Archbold Memorial Hospital.

COUNCIL ON PHARMACY AND CHEMISTRY

REPORT TO THE COUNCIL

The following abstract of recent nomenclature decisions of the Council is authorized for publication.

R. T. Stormont, M.D., *Secretary.*

NEW GENERIC AND BRAND NAMES RECOGNIZED BY THE COUNCIL

The Council collaborates with manufacturers in the selection of generic and brand names for marketed drug preparations presented for acceptance and also for new products still under development or clinical trial. The last report on such names appeared in The Journal, May 3, 1952, p. 63.

The following abstract lists the generic designation, the chemical name, where necessary for information, and the brand name or names simultaneously recognized for the stated firms. In general, a generic name should bear recognizable relation to the chemical name and conform as closely as consistent with brevity and practicality to existing systems of scientific nomenclature. The chief requirement for a brand name is that it should not be therapeutically suggestive.

The listing of a brand name is not to be construed as indicating Council acceptance of the product itself. Products accepted for inclusion in N. N. R. are announced separately.

Basic Aluminum Carbonate Gel for an aluminum hydroxide-carbonate complex: Baseljel (Wyeth, Inc.)

Bimethoxycaine Lactate for Bis[β-(*o*-methoxyphenyl)isopropyl]amine lactate: Isocaine Lactate (The Upjohn Company)

Calcium *p*-Aminosalicylate: Pasara Calcium (Smith-Dorsey)

Carbacrylamine Resins for the following combination of the component ion exchange resins: carbacrylic resin, potassium carbacrylic resin, and polyamine-methylene resin: Carbo-Resin (Eli Lilly and Company)

Carbacrylic Resin and Potassium Carbacrylic Resin for the hydrogen and potassium forms of cross-linked polyacrylic polycarboxylic ion exchange resin

Chlormerodrin for the mercurial diuretic compound 3-chloromercuri-2-methoxypropylurea: Neohydrin (Lakeside Laboratories, Inc.)

Chlorotrianisene for the synthetic estrogen tri-(*p*-anisyl)chloroethylene: Tace (The Wm. S. Merrell Company)

Cyanocobalamin for vitamin B_{12}

Iproniazid for 1-isonicotinyl-2-isopropyl hydrazine: Marsilid (Hoffmann-LaRoche, Inc.)

Isoniazid for isonicotinic acid hydrazid (isonicotinylhydrazine): Nydrazid (E. R. Squibb & Sons) and Niadrin (Endo Products, Inc.)

Neomycorsone for a mixture of neomycin sulfate and cortisone acetate: Neosone (The Upjohn Company)

Pentaerythritol Tetranitrate: Peritrate Tetranitrate (Chilcott Laboratories, Division of the Maltine Company)

Propylhexedrine for 1-cyclohexyl-2-methylaminopropane: Benzedrex (Smith, Kline & French Laboratories)

Testosterone Cyclopentylpropionate for testosterone betacyclopentylpropionate

TREATMENT OF CANCER

The treatment of cancer, once limited to the use of surgery, x-rays, and radium, has been expanded considerably in recent years. New anticancer drugs have been developed, and hormones and radioactive isotopes have been applied to the therapy of malignant disease. These new agents represent valuable additions to the therapeutic program, but the optimistic publicity that has accompanied their use has tended to obscure several facts. In the first place, most of these substances have a relatively narrow range of therapeutic activity. The anticancer drugs, for example, are effective almost exclusively against the lymphomas, the sex steroids act only on a few types of carcinoma, and other substances are similarly limited in their action. Moreover, while these agents may prolong life and make it more comfortable, they are for the most part palliative rather than curative. Permanent cures are still achieved largely with surgery and/or external irradiation administered to patients with early lesions that have not yet metastasized widely. In spite of the many new techniques of treatment, most patients with advanced cancer still die of their disease. The search for truly curative anticancer agents with broad ranges of therapeutic activity continues, but, until such agents are found, surgery and irradiation remain the mainstays of therapy for most types of malignant lesions.

In cancer surgery, progress has been made along several fronts. More radical surgery, made practical by advances in anesthesiology, blood and electrolyte replacement, endocrine substitution, and control of infections, has expanded the concept of operability and made it possible to relieve symptoms and prolong life in many cases of cancer with extensive local spread. Total pneumonectomy for bronchogenic carcinoma, pelvic exenteration for advanced uterine, bladder, and rectal carcinoma, and radical resection of the mandible for carcinoma of the floor of the mouth are examples of this type of procedure. In general, surgical removal of metastatic lesions in distant organs has not proved effective, but in some cases apparent cure has followed the excision of solitary pulmonary lesions derived from uterine or rectal neoplasms, and removal of metastatic adenocarcinomas involving the central nervous system has been found to be a useful procedure. Many palliative operations have been developed for use when direct attack on a tumor is not possible. These include new and improved techniques for relief of malignant obstruction of the urinary, gastrointestinal, or biliary tracts, and operations designed to inhibit tumor growth by alteration of the hormone balance in patients with tumors of the breast and reproductive system. Castration and adrenalectomy are examples of the latter category. These procedures actually constitute an indirect form of chemical therapy.

The field of radiation therapy has also seen remarkable technical advances, many of them by-products of research on atomic energy. Although treatment was once limited to the use of medium voltage x-rays, radium, and radon, the radiotherapist now has at his disposal supervoltage x-ray generators, new types of radiation from the cyclotron, betatron, and other particle accelerators, and many new radioactive substances that can be applied to malignant lesions in a variety of ways. Unfortunately, clinical results have not been greatly improved by the application of these new techniques, although in some instances trial has been on too small a scale to permit final evaluation. Supervoltage (2,000 to 4,000 kv.) x-ray generators, with their increased depth dose per unit skin dose, have not given significantly better results in the treatment of deep-seated cancer than medium voltage (100 to 400 kv.) x-ray machines. The even more penetrating (10,000 to 70,000 kv.) x-rays that can be produced by the betatron have the practical disadvantage of a high skin dose at the point of exit of the beam from the body. It appears that the relative depth dose of x-rays can be increased more effectively and safely by modification of the technique of irradiation than by changes in the quality of the rays. Multiple field therapy, rotational therapy (rotation of the patient with the x-ray beam centered on the lesion), and the protection of the skin with grids or perforated shields have been effective in this regard. Among the newly available types of radiation produced by accelerators, the extremely high-energy, positively charged particles, notably protons, have shown the most promise in the treatment of deep lesions, because of the relatively low ionization that they produce at the surface of the body and the extremely dense ionization toward the end of their range. Neutron irradiation has not given results superior to those obtainable with x-rays. Neutron irradiation of tumors previously infiltrated with material that can be made radioactive by such bombardment is still in the experimental stage.

The use of radioactive isotopes has made the administration of radiation a much more flexible procedure but has not yielded types of radiation or biologic effects fundamentally different from those previously available. Radioactive isotopes in the form of solids, solutions, or colloidal suspensions may now be used not only topically and interstitially but also orally, intravenously, intra-arterially, by instillation into body cavities, and at a distance from the body. These procedures often permit better localization of radiation than has heretofore been possible. Localization may be metabolic, as when systemically administered radioactive iodine (I^{131}) is localized in thyroid tissue, or it may be physical, as when intraperitoneally administered radioactive gold colloids are deposited on the surface of the peritoneum involved by neoplastic implants or are carried to regional nodes via the lymphatics. Immunological localization has been attempted by preparing radioactive organ-specific antibodies, but none of these has been found useful in treatment. Mechanical localization can be achieved by infiltration of tissues with radioactive colloidal suspensions or by interstitial implantation of flexible wires or sutures containing radioactive substances such as cobalt 60 or gold 198. Effective irradiation of superficial lesions can be accomplished with surface applicators containing radioactive phosphorus or strontium, both of which give off beta rays free of penetrating gamma rays. Ruthenium 106 is also a useful source of beta rays. Gamma teletherapy is now possible with machines containing large quantities of radioactive cobalt, and units containing europium 152-154 or cesium 137 are being tested.

The chemical attack on cancer continues to be the subject of intensive research. This approach is based on the principle that the metabolic and mitotic activity of most neoplastic cells is greater than that of most normal cells and that this increased activity makes the neoplastic cell more susceptible to the cytotoxic action of radiation and many chemicals. The fact that some rapidly growing normal cells in the bone marrow and intestine are also damaged by these same agents indicates that the quantitative differential is not great. This, added to the fact that cancer cells, like bacteria, are capable of developing resistance to therapeutic agents, accounts for the many failures in the drug therapy of cancer. Qualitative metabolic differences in cancer cells that can be utilized in treatment have not been described.

Many anticancer drugs have been tested, but only a few have had wide clinical trial. Nitrogen mustards given intravenously have little effect on carcinomas but produce temporary remissions in a high percentage of patients with Hodgkin's disease, lymphatic leukemia, lymphosarcoma, giant follicular lymphoblastoma, and mycosis fungoides. Given intra-arterially, nitrogen mustard has produced local destruction of carcinoma of the tongue, lung, kidney, and other organs, but cures have not been obtained. Triethylene melamine (TEM) given orally or intravenously produces results similar to those obtained with nitrogen mustard in the lymphomas. Folic acid antagonists ("aminopterin" or "a-methopterin") are useful chiefly in acute leukemia of children. Urethan (ethyl carbamate) given orally produces clinical improvement in chronic leukemia, especially in the myelogenous variety.

Other, more questionable, treatments have been proposed. Fowler's solution (potassium arsenite) is effective particularly in Hodgkin's disease and chronic myelogenous leukemia, but treatment must be prolonged and the incidence of toxic manifestations is high. Stilbamidine (4,4′-stilbenedicarboxamidine) and related compounds produce symptomatic relief in multiple myeloma, but there is little objective improvement. A polysaccharide extracted from Serratia marcescens (Bacillus prodigiosus) produces hemorrhagic changes in animal tumors and occasionally a decrease in the size of lymphomatous or sarcomatous tumors in man, but it also produces fever and severe hypotension and is regarded as unpredictable and hazardous. Colchicine, resin of podophyllin, antireticular cytotoxic serum, K-R (an extract prepared from killed Trypanosoma cruzi), H. 11 (an extract of the urine of normal persons), and "krebiozen" are among the agents that have been advocated in some quarters but have not been generally accepted by experts in the cancer field.

Hormone therapy has been found beneficial only in certain kinds of cancer, and in these it is believed that the environment of the tumor rather than the tumor itself is affected. Estrogens produce regression of local and metastatic lesions in carcinoma of the prostate and may prolong life for many years. They are also of benefit in postmenopausal carcinoma of the breast and appear to have some effect on carcinoma of the bladder and chorioepithelioma. Androgens have a palliative effect in carcinoma of the breast with extensive metastasis. There is equivocal evidence that progesterone has value in carcinoma of the breast, cervix, and prostate. Cortisone and corticotropin have no consistent effect on the objective manifestations of carcinoma, but they do inhibit to some extent the growth of the malignant lymphomas. In the acute leukemias they produce spectacular remissions of short duration; in chronic leukemias the results are unpredictable, with aggravation of the disease sometimes occurring. The one feature of chronic leukemia that is regularly benefited, however, is the hypersplenic phase. When hemolytic, neutropenic, and thrombopenic crises occur, cortisone or corticotropin produces the same benefits as splenectomy, even when x-rays and other measures have failed to do so.

Other approaches to the therapy of cancer that have been employed experimentally include the use of viruses that selectively attack and destroy neoplastic cells, the attempt to stimulate immunity to cancer in the host by inoculation with extracts of tumor and other tissues, and the destruction of superficial tumors with ultrasonic waves. None of these approaches is yet of practical value in man.

In the current preoccupation with specific therapy, sight is often lost of the fact that the patient as well as the cancer must be treated. The patient's morale must be maintained, and general supportive treatment must be utilized. The relief of secondary infection with antibiotics, of disturbances in fluid, electrolyte, and nutritional balance with parenteral fluids, of any associated congestive heart failure with standard remedies, and of anemia with transfusions will often do more to make the patient comfortable than any specific measures available. It should be noted, however, that iron therapy has no value except in the treatment of hypochromic anemia following hemorrhage. Liver extract and supplementary vitamin B_{12} are equally valueless unless there is a specific deficiency of these substances.

The solution to the problem of specific anticancer therapy awaits a better understanding not only of the metabolism of cancer cells but of the mechanism of normal growth as well. For the acquisition of this knowledge unrestricted basic research may well be as important as "project" or restricted research. Support and coordination of research is being provided in the United States on an unprecedented scale by such organizations as the American Cancer Society, the American Association for Cancer Research, the National Cancer Institute, the Atomic Energy Commission, the Committee on Growth of the National Research Council, and the Committee on Research of the A. M. A.'s Council on Pharmacy and

Chemistry. An example of the type of activity sponsored by the last-named committee is the continuing cooperative study on the use of steroid hormones in the treatment of advanced breast, thyroid, and genitourinary carcinoma. The results of the breast carcinoma study, in which 45 clinics and 14 pharmaceutical firms participated, have been published in THE JOURNAL.[1]

The development of improved methods of cancer therapy seems certain. In the meantime, over-optimism concerning new remedies must be guarded against assiduously. Every effort must be made on the part of scientists, science writers, and pharmaceutical manufacturers to prevent the release to the lay press of overenthusiastic news stories of new "wonder drugs" or therapeutic procedures. The false hopes raised by such stories have caused patients to postpone urgent surgery or to refuse irradiation until their lesions have advanced beyond all hope of control. Persons in high government office and other responsible positions also have an obligation to the public to refrain from promoting new and inadequately tested therapeutic measures. Such misguided activity can result in incalculable harm to the health of the public.

1951 EXPENDITURES FOR MEDICAL CARE

The Bureau of Medical Economic Research has recently published another item in its series on personal consumer expenditures for medical care.[1] The basic data are from the July, 1952, issue of the *Survey of Current Business,* United States Department of Commerce. New data are given for 1951 and some slight revisions of the previously published data for 1949 and 1950.

Briefly stated, the percentages of total personal consumer expenditures spent for medical care and for each of the major items of medical care were about the same in 1951 as they were in 1950. The percentage spent for medical care was 4.3% in 1951 and 4.3%, according to revised data, for 1949 and 1950. The percentages ent for the services of physicians and of hospitals continue to be 1.2 and 1.0 respectively. The percentage of the medical care dollar spent on physicians' services in 1951 was 28.1, as compared with 28.3 in 1950 and 28.9 in 1949 according to the revised data for the two earlier years. On the other hand, the share of the medical care dollar going to hospitals reached an all-time high of 23.8% in 1951 and the revised data indicate 22.0% for 1949 and 23.4% for 1950. The dentists' share of the medical care dollar was 11.9% in 1949, 11.5% in 1950, and 11.0% in 1951.

Personal consumer expenditures for medical care rose from 7.8 billion dollars in 1949 to 8.4 billion dollars in 1950 to 9.0 billion dollars in 1951. Total personal consumer expenditures for all goods and services, however, rose slightly faster, from 180.6 billion dollars in 1949 to 194.3 billion dollars in 1950 to 208.0 billion dollars in 1951. Thus the American people continue to devote only slightly more than 4% of their total consumer expenditures to medical care items, among which hospital care bulks larger and larger.

GENERAL PRACTITIONER AWARD

The General Practitioner Award was presented for the first time in January, 1948, at the Association's meeting in Cleveland. Since then it has been awarded annually at the midyear session. It has been the practice for the Board of Trustees to select three names from those submitted by the state societies and present them to the House of Delegates for its choice. At its meeting in Chicago in June, 1952, the House approved the following communication from the Board of Trustees:

> It is believed that a much more dignified and fair approach would be to have the Chairman of the Board appoint an impartial committee, to remain anonymous until after the award is made, which would study the credentials and choose from the nominations submitted the general practitioner most qualified for the honor.

To meet the wishes of the House, biographical material submitted by various state medical societies for the General Practitioner Award should be in the office of the Secretary of the American Medical Association no later than Nov. 1.

SCIENTIFIC EXHIBIT, DENVER SESSION

The Scientific Exhibit will again be one of the features of the Clinical Session in Denver, Dec. 2 to 5, 1952. All activities of the session, except the House of Delegates, will be housed in the remodeled and enlarged Municipal Auditorium. The Scientific Exhibit will be located on the ground floor of the auditorium, together with facilities for colored television, motion pictures, and several of the meeting rooms.

Application blanks are now available for space in the Scientific Exhibit, and prospective authors of exhibits should make application as soon as possible. Attention is called to the fact that the Denver Session is a clinical meeting and hence emphasis is placed largely on the clinical aspects of medicine rather than on research activities.

The Committee on Scientific Exhibit is composed of three members of the Board of Trustees: L. W. Larson, M.D., Bismarck, N. D., chairman; Thomas P. Murdock, M.D., Meriden, Conn.; and James R. McVay, M.D., Kansas City, Mo. The subcommittee on Scientific Exhibit in Denver includes Dumont H. Clark, M.D., chairman; Thomas M. Van Berger, M.D.; and Marvin E. Johnson, M.D.

Application blanks for space may be obtained from the Director, Scientific Exhibit, American Medical Association, 535 N. Dearborn St., Chicago 10.

Dearborn St., Chicago 10.

MEDICAL NEWS

CALIFORNIA

Warning—Epidemic Encephalitis.—Dr. Wilton L. Halverson, state director of public health, has issued a warning that encephalitis may become epidemic in the Central Valley of California this year unless intensified action against the mosquito that transmits the disease is taken by control agencies and individual householders alike. The threat of a mosquito-borne epidemic is indicated in reports of both human and equine cases of encephalitis in the San Joaquin Valley, coupled with the appearance of extremely large numbers of Culex tarsalis mosquitoes.

At a meeting of representatives of the vector control advisory committee, State Department of Public Health, and representatives of mosquito abatement districts in the Central Valley, preventive and remedial measures were suggested. Individual householders were urged to eliminate mosquito breeding sources around their premises, keep adult mosquitoes out of the house by careful screening of doors and windows, and use hand sprays or aerosol bombs to kill mosquitoes getting indoors. All persons, and particularly children, were advised to remain indoors as much as possible during evening hours, when Culex tarsalis usually attacks, and to use mosquito repellents when outdoors.

Health departments were asked to be on the alert, maintaining close contact with private physicians, in order to provide an up-to-the-minute statewide picture, with the earliest possible warning of epidemic conditions. Encephalitis cases in the high-prevalence areas of the Central Valley normally reach a peak in July, August, and September. Mosquito abatement districts were urged to intensify their control measures directed specifically at the Culex tarsalis species, and irrigation districts and individual ranchers were asked to support the control measures, giving particular attention to irrigation practices to prevent unnecessary standing water, which would create mosquito breeding places.

ILLINOIS

Health at the State Fair.—Many phases of health are emphasized at the Illinois Centennial State Fair, which is being held at Springfield Aug. 8-17. In addition to displays of health subjects throughout the fairgrounds, free movies, and dental and chest x-ray examinations are provided. Inside the Illinois Building are displayed improvements in sanitation during the past 100 years. As part of the tuberculosis case finding program, the State Department of Public Health, in cooperation with the Illinois Tuberculosis Association, is offering x-ray examinations of the chest. The Department of Public Health is also sponsoring a special "health tent" with exhibits and motion pictures on many health subjects.

Chicago

Fellowship in Pediatric Cardiology.—The Children's Division of Cook County Hospital in Chicago has an opening for a fellow in pediatric cardiology. Training in angiocardiography and catheterization will be available if desired. Information may be obtained from Dr. Benjamin M. Gasul, 700 S. Wood St., Cook County Children's Hospital, Chicago.

Dr. MacEachern Honored.—Dr. Malcom T. MacEachern, director of professional relations for the American Hospital Association, was presented with a badge bearing the coat of arms of the Comité des Hôpitaux du Quebec (the Committee of Catholic Hospitals of Quebec) and a citation in recognition of his work in the hospital field, during the session of the Comité in Quebec City, June 23-25. In July Dr. MacEachern was in Brazil, South America, where he gave a three week lecture course to students in hospital administration at the University of São Paulo. While in Brazil he also participated in an Institute for Hospital Administrators and served as consultant on local, regional, state, and national organization of hospitals. The trip was arranged under the auspices of the University of São Paulo.

IOWA

State Medical Society Election.—At its meeting in Des Moines, April 27-30, the Iowa State Medical Society elected Dr. Ben T. Whitaker, Boone, president; Dr. Robert N. Larimer, Sioux City, president-elect; Dr. Elias B. Howell, Ottumwa, first vice-president; Dr. Lester C. Kern, Waverly, second vice-president; Dr. Allan B. Phillips, Des Moines, secretary; and Dr. N. Boyd Anderson, Des Moines, treasurer.

Dr. Barnes Retires from Faculty.—Dr. Milford E. Barnes, since 1930 head of the department of hygiene and preventive medicine, University of Iowa, was honored at a testimonial dinner June 4. Dr. Barnes, whose retirement from the university faculty was recently announced, has served as director of the university's department of health since 1930; and since 1943 he has been consulting director of the Iowa State Hygiene Laboratory, which he served as director for many years.

Before coming to the university he was a field director under the international health division of the Rockefeller Foundation. A wrist watch and a morocco-bound book, containing more than 100 letters from former students and co-workers, was presented to Dr. Barnes. Greetings from individual friends, societies, and organizations in various countries were read.

MINNESOTA

Dr. Buie Receives Alumni Award.—Dr. Louis A. Buie, professor of surgery in the Mayo Foundation, University of Minnesota, Rochester, has been given the 1952 Alumni Honor Award and Gold Key by the Medical Alumni Association of the University of Maryland "for outstanding contributions to medicine and distinguished service to mankind." The presentation was made June 5, when Dr. Buie addressed the association on "The Fruit of Loyal Nature and of Noble Mind."

Before becoming chief of the department of proctology at the Mayo Clinic in 1919, Dr. Buie was affiliated with the University of Maryland hospital and James Lawrence Kernan Hospital and Industrial School for Crippled Children in Baltimore. He is a past president of the American Proctologic Society, secretary of the American Board of Proctology, chairman of the Council on the Constitution and By-Laws of the American Medical Association, and a member of the Judicial Council of the Association and the Committee on Education and Publications of the National Foundation for Infantile Paralysis, Inc.

NEW YORK

Genesee County Sesquicentennial.—Medicine played a prominent part in the week-long observance of Genesee County's Sesquicentennial celebration through the activities of the Genesee County Medical Society and the Woman's Auxiliary of the Genesee Memorial Hospital. The medical group had a float in the Batavia parade portraying the advance of medicine since the founding of Genesee County 150 years ago. Dr. Charles M. Graney, Batavia, was chairman of the County Medical Society's Exhibition Committee; Dr. Alfred L. George, Batavia, wrote and directed the pageant, which had a cast of 500 characters.

New York City

Dr. Wolf Appointed Dean in Vermont.—Dr. George A. Wolf Jr., director of the outpatient department of New York Hospital and assistant professor of clinical medicine at Cornell Medical College, has been appointed dean of the college of medicine of the University of Vermont, Burlington, and professor of clinical medicine. He succeeds Dr. William E. Brown, who retired June 30.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Report on Tuberculosis.—In its annual report for the 50th year of an organized drive against tuberculosis, the New York Tuberculosis and Health Association points out that though fewer persons are dying of the disease today, the incidence continues at an alarmingly high level and out of proportion to the medical and social progress of the last half century. During the last 20 years the incidence has not materially changed: there were 17,645 cases of pulmonary tuberculosis in New York at the end of 1931 as compared to 17,911 cases on Dec. 31, 1951. A slow but steady increase of cases has marked the last five years. Of the 13 city hospitals caring for tuberculosis patients, 6 have more than 100% bed occupancy; 85% of capacity is the normal hospital occupancy, but according to the report none of the 13 operates at this figure.

OKLAHOMA

Insurance Company Cancels Malpractice Policy.—The London and Lancashire Indemnity Company of Hartford, Conn., has cancelled the master policy held with the Oklahoma State Medical Association for the writing of malpractice insurance for its members. The company stated that it was withdrawing from this field of insurance. Physicians whose malpractice insurance was with the London and Lancashire will find it necessary to place this coverage with companies that are now writing it in Oklahoma. The insurance committee of the association is attempting to negotiate a new contract with another company. Over 985 members of the association held contracts with the London and Lancashire.

PENNSYLVANIA

100 Years of Pennsylvania Medicine.—"A Century of Medicine, 1848-1948," a history of medicine in the Commonwealth of Pennsylvania, has just been published by the State Medical Society. Among the medical "firsts" in this country, which it lists for Pennsylvania, are the following: the first general hospital, first permanent medical periodical, and the first board of health. The first woman's medical school in the world was established in Philadelphia more than a century ago. The Medical Society of the State of Pennsylvania was the 16th state society to be organized, coming into being one year after the founding of the American Medical Association.

Philadelphia

Antivirus Research.—Schenley Laboratories, Inc., Lawrenceburg, Ind., has announced a grant of $17,000 to the Langbord Virus Laboratory at Hahnemann Medical College and Hospital, for antivirus research. The studies will be made by Dr. Bernard A. Briody, Ph.D., director of the virus laboratory.

Dr. Long Appointed to UNESCO Commission.—Dr. Esmond Ray Long was recently appointed a member of the U. S. National Commission of UNESCO, as representative of the National Academy of Sciences, National Research Council. He succeeds Detlev W. Bronk, Ph.D., president of Johns Hopkins University, Baltimore.

Director of the Henry Phipps Institute for Study, Treatment and Prevention of Tuberculosis, Dr. Long served as chief consultant on tuberculosis to the Surgeon General's Office, U. S. Army, during World War II, and later directed the tuberculosis section of public health in the U. S. zone in Germany. He has served as president of the National Tuberculosis Association, American Association of Pathologists and Bacteriologists, and the American Association of the History of Medicine.

SOUTH CAROLINA

Man of the Year.—Dr. Walter R. Mead, Florence, was the recipient recently of the "Man of the Year" civic service award, sponsored annually by the Rotary, Kiwanis, Optimist, Lions, and Exchange clubs of Florence.

Cancer Award.—Dr. Thomas A. Pitts, chairman of the Board of Trustees of the Medical College of the State of South Carolina, Charleston, was awarded the medal of the American Cancer Society for outstanding service in the cancer program for 1951. The citation was made by the South Carolina Division of the American Cancer Society, "in recognition of distinguished service in the control of cancer." He has been director of the South Carolina Baptist Hospital Cancer Clinic since it was organized and has also directed a cancer detection clinic there for the past four or five years.

VIRGINIA

Dr. Caudill Honored.—Dr. Walter Cleveland Caudill of Pearisburg was recently honored by his alma mater, the Medical College of Virginia in Richmond, which conferred on him the honorary degree of master of science in general medicine. Dr. Caudill was president of the Medical Society of Virginia (1950-1951), and in 1951 the House of Delegates of the Medical Society of Virginia selected him as "General Practitioner of the Year." For several years he has served in the Virginia State Legislature.

WISCONSIN

Health Day for Business Executives.—On July 30 the University of Wisconsin Industrial Management Institute sponsored an executive leadership program for business men. The faculty of the University of Wisconsin Medical School, Madison, cooperated in providing information on the symptoms of coronary thrombosis, nervous disorders, cancer, and tuberculosis. Dr. John W. Brown, director of the university's department of student health, who was in charge of the health day program, stated that the program was planned "to help the group understand how medical men diagnose and treat ailments that are especially prevalent among businessmen . . . to make available to business executives the most advanced scientific knowledge that will help lengthen their lives."

GENERAL

Dates Changed for Graduate Course in Urology.—The American Urological Association announces that the postgraduate course in urology, known as the South Central Section Seminar, which was scheduled to be given in Kansas City, Mo., Dec. 14-18 (The Journal, June 14, p. 698), will be given instead in the same city on Jan. 11-14, 1953. Information may be obtained from the headquarters of the association, 102-110 Second Ave., S.W., Rochester, Minn.

Proposed Nation-Wide Medical Code for Boxing.—Measures designed to protect young boxers and to promote the exchange of information on the medical effects of athletics were discussed at a symposium July 27 in New York, under the sponsorship of the State Athletic Commission. Dr. Marvin A. Stevens, New York, member of the Medical Advisory Board of the commission, was chairman.

A plea for establishing national standards to protect boxers was made by Dr. Frank R. Ferlaino, New York, former director, State Athletic Commission's medical advisory board. Among the steps suggested by Dr. Ferlaino were the establishment of a national medical sports association for interchanging information, recognized medical criteria for stopping bouts, standardized medical equipment, and safer gloves, mats, and mouthpieces for boxers. The National Boxing Association will hold a meeting on the Medical Aspects of Boxing in Montreal, Canada, Sept. 8-10.

Dermatologists Meet in San Francisco.—The Pacific Dermatologic Association will meet in San Francisco Aug. 29-30 under the presidency of Dr. Nelson P. Anderson, Los Angeles. On Friday the sessions at the Palace Hotel will open with the presidential address at 9 a. m., which will be followed at 9:20 by a talk on "The Diagnostic Pitfalls in Dermal Pathology" by Dr. Marcus R. Caro of Chicago, clinical professor of dermatology, University of Illinois. Brief reports of scientific activities will be given by the universities of Colorado, Utah, Washington, Oregon, Southern California, California at Los Angeles, and California, Stanford University, and the College of Medical Evangelists.

The Saturday session, which will be held in the Letterman Army Hospital, will open at 9 a. m. with a demonstration of clinical techniques. At 10:30 a. m. there will be a report from the International College of Dermatology in London under the chairmanship of Dr. Norman N. Epstein of San Francisco.

Discussion roundtable groups will be held during the luncheon at the hospital, which will be followed by a clinical meeting of the hospital.

On Sunday at 9 a. m. there will be a seminar in histopathology at Letterman Army Hospital.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States and its territories and possessions in the weeks ended as indicated:

Area	July 19, 1952	July 12, 1952	July 21, 1951

Total	1,405	1,060	798

During the "disease year," which began with the week ended July 5, a total of 5,406 cases of poliomyelitis had been reported (week ended July 19) as compared with 3,351 for the same period in 1951; in 1949, the corresponding figure was 5,313.

FOREIGN

Congress of Therapeutics.—The International Congress of Therapeutics will be held in Madrid, Spain, Oct. 16-18. The main topics for discussion will be potassium, massive hormonotherapy, and radioisotopes. Among the speakers will be Paul F. Hahn, Ph.D., Nashville, Tenn., who will discuss "Tumor Therapy by Radioisotopes."

LATIN AMERICA

Dr. Kemeny Honored.—Dr. Esteban Kemeny, director of the School of Dietetics, Santiago, Chile, has been elected president of the Nutrition Society of Chile. He recently visited the United States under the sponsorship of the Institute of Inter-American Affairs for the purpose of observing American dietetic methods.

CORRECTION

Annual License Renewal Not Required in Florida.—On page 506 of the May 31, 1952, JOURNAL under the heading "Annual Registration" is a statement to the effect that a new Florida law requires annual renewal of licenses of practitioners of medicine. Annual renewal is not required. The statement should have been to the effect that the Florida law requires annual registration of such licenses with the state board of health.

MEETINGS

American Medical Association Public Relations Institute, Edgewater Beach Hotel, Chicago, Sept. 4-5. Mr. Leo E. Brown, 535 N. Dearborn St., Chicago 10, Director.

Alaska Territorial Medical Association, Anchorage, Aug. 21-23. Dr. William P. Blanton, P. O. Box 2569, Juneau, Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, The Homestead, Hot Springs, Va., Sept. 4-6. Dr. William F. Mengert, 2211 Oak Lawn Ave., Dallas, Texas, Secretary.

American College of Surgeons, Waldorf-Astoria, New York, Sept. 22-26. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Secretary.

American Congress of Physical Medicine, Roosevelt Hotel, New York, Aug. 25-29. Dr. Frances Baker, One Tilton Ave., San Mateo, Calif., Secretary.

American Hospital Association, Philadelphia, Sept. 15-18. Mr. George Bugbee, 18 East Division St., Chicago 10, Executive Director

American Medical Writers' Association, Jefferson Hotel, St. Louis, Oct. 1. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

American Physiological Socety, New Orleans, Sept. 4-6. Dr. E. F. Adolph, University of Rochester School of Medicine and Dentistry, Rochester, N. Y., Secretary.

American Roentgen Ray Society, Shamrock Hotel, Houston, Texas, Sept. 23-26. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

American Society of Maxillofacial Surgeons, Hotel del Coronado, San Diego, Calif., Sept. 10-13. Dr. Casper M. Epsteen, 25 East Washington St., Chicago 2, Secretary.

Annual Gulf Coast Regional Conference on Industrial Health, Rice Hotel, Houston, Tex., Sept. 24-27. Dr. W. H. Hamrick, P. O. Box 2371, Houston, Tex., Chairman.

Biological Photographic Association, Hotel New Yorker, New York, Sept. 10-12. Mr. Lloyd E. Varden, Pavelle Color, Inc., 533 W. 57th St., New York 19, Secretary.

Colorado State Medical Society, Stanley Hotel, Estes Park, Sept. 9-12. Mr. Harvey T. Sethman, 835 Republic Bldg., Denver 2, Executive Secretary.

Constantinian Society, Lake Placid Club, Lake Placid, N. Y., Oct. 1-4. Dr. C. F. Shook, P. O. Box 1035-36, Toledo 1, Ohio, Secretary.

Medical Society of Delaware, Rehoboth, Sept. 8-10. Dr. Andrew M. Gehret, 822 North American Bldg., Wilmington, Secretary.

Medical Society of the District of Columbia, Hotel Statler, Washington, Sept. 29-Oct. 1. Mr. Theodore Wiprud, 1718 M St. N.W., Washington, Secretary.

Medical Society of the State of Pennsylvania, Bellevue-Stratford Hotel, Philadelphia, Sept. 28-Oct. 2. Dr. Walter F. Donaldson, 500 Penn Ave., Pittsburgh 22, Secretary.

Medical Society of Virginia, Jefferson Hotel, Richmond, Sept. 28-Oct. 1. Mr. Robert L. Howard, 1105 West Franklin St., Richmond, Executive Secretary.

Michigan State Medical Society, Book-Cadillac Hotel, Detroit, Sept. 24-26. Dr. L. Fernald Foster, 606 Townsend St., Lansing 15, Secretary.

Mississippi Valley Medical Society, Jefferson Hotel, St. Louis, Oct. 1-3. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Montana Medical Association, Florence Hotel, Missoula, Sept. 18-21. Mr. L. R. Hegland, 104 North Broadway, Billings, Executive Secretary.

National Medical Association, Chicago, Aug. 11-15. Dr. John T. Givens, 1108 Church St., Norfolk 10, Va., General Secretary.

Neurosurgical Society of America, The Cloister, Sea Island, Ga., Sept. 18-20. Dr. C. D. Hawkes, 22 North Manassas St., Memphis 5, Tenn., Secretary.

Nevada State Medical Association, Reno, Aug. 21-23. Dr William A. O'Brien III, 505 Chestnut St., Reno, Secretary.

New Hampshire Medical Society, Mt. Washington Hotel, Bretton Woods, Sept. 7-9. Dr. Deering G. Smith, 44 Chester St., Nashua, Secretary.

North Pacific Pediatric Society, Challenger Inn, Sun Valley, Idaho, Sept. 19-20. Dr. S. Gorham Babson, 1107 S.W. 13th Ave., Portland 5, Ore., Secretary.

North Pacific Society of Internal Medicine, Sun Valley, Idaho, Sept. 19-20. Dr. Robert L. King, 1115 Terry Ave., Seattle 1, Wash., Secretary.

North Texas-Southern Oklahoma Fall Clinical Conference, Wichita Falls, Texas, Sept. 17. Dr. E. Aubrey Cox, Hamilton Bldg., Wichita Falls, Texas, Chairman.

Piedmont Proctologic Society, Savannah Beach, Ga., Aug. 23. Dr. B. Richard Jackson, 224 Hillsboro St., Raleigh, N. C., Secretary.

Reno Surgical Society *Conference*, Reno, Nevada, Aug. 21-23. Dr. Olin C. Moulton, 130 N. *Virginia St.*, Reno, Nevada, Chairman.

Tri-State Medical Society of Texas, Louisiana and Arkansas, Texarkana, Texas, Oct. 2-3. Dr. Albert M. Hand, 619 Main St., Texarkana, Texas, Secretary.

U. S. Chapter, International College of Surgeons, Conrad Hilton Hotel, Chicago, Sept. 2-5. Dr. Arnold S. Jackson, 1516 Lake Shore Drive, Chicago, Executive Secretary.

Utah State Medical Association, Salt Lake City, Sept. 4-6. Dr. T. C. Weggeland, 42 S. Fifth East St., Salt Lake City, Secretary.

Vermont State Medical Society, Mt. Washington Hotel, Bretton Woods, N. H., Sept. 7-9. Dr. James P. Hammond, 128 Merchants Row, Rutland, Secretary.

Washington State Medical *Association*, *Olympic* Hotel, Seattle, Sept. 13-17. Dr. Bruce *Zimmerman*, 338 White-Henry-Stuart Bldg., Seattle, Secretary.

INTERNATIONAL

Aero Medical Association Interim Meeting, Paris, France, Sept. 26-28. Dr. Armand Robert, 2 Rue Marbeuf, *Paris 8e, France*, Secretary.

American Congress of Industrial *Medicine*, Rio de Janeiro, Brazil, Sept. 20-28. Prof. Dr. Jose Pedro Reggi, Calle *Arenales No.* 981 Buenos Aires, Argentina, Director General.

Australasian Medical Congress, Melbourne Victoria, Australia, Aug. 22-30. Dr. C. H. Dickson, Medical Society Hall, 426 Albert St., East Melbourne, Victoria, Australia, General Secretary.

Congress of International *Institute* of Embryology, University of Utrecht, *Zoological* Laboratory, Utrecht, Netherlands, Aug. 27-31. Dr. M. W. Woerdeman, Amsterdam, Holland, President.

European Congress of Cardiology, University of London, Bloomsbury, W.C.1, England, Sept. 10-12. Dr. K. Shirley Smith, 35 Wimpole St., London, W.1, England, Secretary.

European Society of Cardiovascular Surgery, Strasbourg, France, Oct. 3-4. Sir James Learmonth, Department of Surgery, University New Buildings, Edinburgh 8, Scotland.

Interamerican Cardiological Congress, Buenos Aires, Argentina, Aug. 31-Sept. 7. Dr. Blas Moia, Larrea 1132, Buenos Aires, Argentina, Secretary-General.

Inter-American Congress of Public Health, Havana, Cuba. Sept. 26-Oct. 1. Pan-American Sanitary Bureau, 2001 Connecticut Ave., Washington, D. C

Inter-American Congress of Radiology, Mexico City, Mexico, Nov. 2-8. Dr. Guido Torres Martinez, Marsella No. 11, Mexico, D.F., Secretary-General.

International Congress of Anthropology and Ethnology, Vienna, Austria, Sept. 1-8. For information write: Secretaries, Royal Anthropological Institute, 52 Upper Bedford Place, London, W.C.1, England.

International Congress on Diseases of the Chest, Rio de Janeiro, Brazil, Aug. 24-30. Mr. Murray Kornfeld, 112 East Chestnut St., Chicago 11, Illinois, Executive Secretary.

International Congress of Haematology, Mar del Plata, Argentina, Sept. 21-26. Dr. Carlos Reussi, Anchorena 1710, Buenos Aires, Argentina, Secretary.

International Congress of the History of Medicine, Nice-Cannes, France, and Monaco, Sept. 8-14. Dr. F. A. Sondervorst, 124 Avenue es Allies, Louvain, Belgium, Secretary-General.

ernational Congress on Hydatid Disease, Santiago, Chile, Nov. 21-24. Organizing Committee, P. O. Box 9183, Santiago, Chile.

International Congress of Internal Medicine, Friends House, London, N.W.1, Eng. Sept. 15-18. Sir Harold Boldero, 12 Pall Mall East, London, S.W.1, England, Secretary.

International Congress of Medical Press, Venice, Italy, Oct. 4-5. Dr. Bruno de Biasio, S. Marco 4646, Venice, Italy, Secretary.

International Congress on Medical Records, London, England, Sept. 7-12. Miss Gwen Perkins, 120 C Street S.E., Washington, D. C., Chairman.

International Congress of Military Medicine and Pharmacy, Montevideo, Uruguay, March 1-7, 1953. Dirreccion General del Servico de Sanitad Militar, 8 de Octubre y Mariano Moreno, Montevideo, Uruguay, Secretariat of the Congress.

International Congress on Neuropathology, Rome, *Italy*, *Sept.* 8-13. Dr. Armando Ferraro, 722 W. 168th St., New York, N. Y., U. S. A., Secretary General.

International Congress of Otorhinolaryngology, Amsterdam, Netherlands, June 8-15, 1953. Dr. W. H. Struben, J. J. Viottastraat 1, Amsterdam, Netherlands, Secretary.

International Congress of Radiology, Copenhagen, Denmark, July 19-25, 1953. Professor Flemming Norgaard, 10 Oster Voldgade, Copenhagen K., Denmark, Secretary General.

International Congress of Therapeutics, Madrid, Spain, Oct. 16-18. Professor Armijo, Instituto de *Farmacologia*, Cuidad Universitaria, Madrid, Spain, Secretary.

International Congress of Urology, The Waldorf-Astoria, New York, N. Y., U. S. A., Sept. 15-18. Dr. John A. *Taylor*, 2 East 54th St., New York, N. Y., U. S. A., Secretary-General.

International Hospital Congress, *London*, England, May 25-30, 1953. Capt. J. E. Stone, 10 Old Jewry, London, EC2, England, Hon. Secretary.

International Study Conference on Child Welfare, Bombay, India, Dec. 5-12. For information write: All India Save the *Children* Committee, 5 Carmichael Road, Bombay, India.

International Union Against Tuberculosis, Rio de Janeiro, Brazil, Aug. 24-27. Prof. Etienne Bernard, 66 Blvd. St. Michel, Paris 6e, France, Secretary-General.

Medical Women's International Association, Vichy, France, Sept. 12-16. Dr. Margaret M. Wurts, 27 East Wellesley Road, Montclair, N. J., *U.* S. A., National Secretary.

Neuroradiological Symposium, Stockholm, Sweden, Sept. 17-20. Docent Ake Lindbom, Symposium Neuroradiologicum, Serafimerlasarettet, Stockholm K., Sweden, Secretary.

Pan American Congress of the Medical Press, Buenos Aires, Argentine, July 12-16, 1953. Secretaria del Congress, 763 Uriburu, Buenos Aires, Argentine.

World Congress of *Jewish Physicians*, Jerusalem, Israel, Aug. 10-14. Secretariat: ℅ Israel *Medical* Association, Rehov Mesilat Yesharim, Beth Kovatz, Jerusalem, Israel.

World Congress of Medicine, *Montecatini*, Italy, Oct. 16-18. Secretariat: Corso Trieste, 65, *Rome*, *Italy*.

World Federation of Mental Health, Brussels, Belgium, Aug. 25-Sept. 1. Dr. J. R. Rees, 19 Manchester St., London, W.1, England, Secretary.

World Medical Association, Athens, Greece, Oct. 12-16. Dr. Louis H. Bauer, 2 East 103d St., New York 29, N. Y., Secretary General.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Part I*, Sept. 8-10. All centers *where there* are *five* or more candidates. Exec. Sec., Dr. John P. Hubbard, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* Swampscott, Mass., Sept. 28-*Oct.* 1. Sec., Dr. C. B. Hickcox, 80 Seymour St., Hartford 15.

American Board of Dermatology and Syphilology: *Written.* Various Centers, September 1953. Final date for filing *applications* was May 1. All candidates are now required to take the written examination. *Oral.* Philadelphia, October 1953. Ex. Sec., Miss Janet Newkirk, 66 East 66th St., New York 21.

American Board of Internal Medicine: *Written.* Various centers and overseas, Oct. 20. Closing date for the acceptance of applications for the written examination was May 1. *Oral. San Francisco*, Sept. 3-6; *Philadelphia*, Nov. 13-14 and Washington, D. C., Nov. 17-18. Exec. Sec.-Treas., Dr. William A. Werrell, 1 West Main Street, Madison 3.

American Board of Neurological Surgery: *Written.* New Haven, Sept. 19-21. *Oral.* Chicago, May or June 1953. Final date for filing application for the oral examination is Jan. 15, 1953. Sec., Dr. W. J. German, 789 Howard Ave., New Haven 4, Conn.

American Board of Obstetrics and Gynecology: *Written.* Various Centers, Feb. 6, 1953. Final date for filing applications is Nov. 1. Sec., Dr. R. L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written.* Various Centers, January 1953. Final date for filing applications was July 1. *Practical.* Chicago, Oct. 6-10 and New York City, June 6-10, 1953. Sec., Dr. Edwin B. Dunphy, 56 Ivie Road, Cape Cottage, Maine.

American Board of Orthopaedic Surgery: The deadline for the receipt of applications for the 1953 Part II examinations is Aug. 15. Sec., Dr. Harold A. Sofield, 122 S. Michigan Ave., Chicago.

American Board of Otolaryngology: *Written.* Chicago, Oct. 6-10. *Oral.* Chicago, Oct. 6-10 and New Orleans, April 21-25, 1953. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City.

American Board of Pathology: *Written and Oral.* Pathologic Anatomy and Clinical Pathology examination. Chicago, Oct. 9-11. Sec., Dr. William B. Wartman, 303 E. Chicago Ave., Chicago 11.

American Board of Pediatrics: *Oral.* Chicago, Oct. 24-26; Boston, Dec. 5-7. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: *Oral and Written.* New York, Sept. 26-28. Final date for filing of case reports is Aug. 15 Sec., Dr. Bradford Cannon, 4647 Pershing Ave., St. Louis 8.

American Board of Preventive Medicine and Public Health: Cleveland, Oct. 18-20. Sec., Dr. E. L. Stebbins, 615 N. Wolfe St., Baltimore.

American Board of Proctology: *Oral and Written.* Philadelphia, Sept. 27-28. Sec., Dr. Louis A. Buie, 102-110 Second Ave., S.W., Rochester, *Minn.*

American Board of Psychiatry and Neurology: New York City, Dec. 15-16. Final date for filing applications is Sept. 15. Sec.-Treas., Dr. David A. Boyd, Jr., 102-110 Second Ave. S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Dec. 1-7. Final date for filing application was June 1. *Oral.* Tampa, April 8-15. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers. October 1952. Final date for filing application was July 1. *Written.* Various Centers, March 1953. Final date for filing application is Dec. 1. Sec., *Dr.* J. Stewart Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: *Written.* Various Centers, December. *Oral.* Chicago, Feb. 7-11. Sec., Dr. Harry Culver, 30 Westwood Road, Minneapolis 16, Minn.

Board of Thoracic Surgery: *Written.* Various Centers, Sept. 5. Sec., Dr. William M. Tuttle, 1151 Taylor Ave, Detroit 2.

DEATHS

Gill, William Davis ⊕ San Antonio, Texas; born in Dallas, Texas, Nov. 24, 1895; Vanderbilt University School of Medicine, Nashville, Tenn., 1917; specialist certified by the American Board of Ophthalmology and American Board of Otolaryngology; member of the Southern Medical Association, Texas Ophthalmological and Otolaryngological Society, American Academy of Ophthalmology and Otolaryngology, American Laryngological Association, American Laryngological, Rhinological and Otological Society, and the Association for Research in Ophthalmology; fellow of the American College of Surgeons; past chairman of the city board of health; served in the medical corps of the regular army from 1919 to 1927; awarded the French Medaille d'Honneur for services rendered during World War I; member of the staff, Nix Memorial Hospital, Medical Arts Hospital, and Santa Rosa Hospital, where he died May 24, aged 56, of chronic myocarditis.

Tedder, James William ⊕ New Orleans; born in Magee, Miss., April 1, 1908; Tulane University of Louisiana School of Medicine, New Orleans, 1932; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology; formerly on the faculty of Louisiana University Medical Center; served during World War II, and was awarded the Bronze Star for heroic and meritorious service to survivors of a torpedoed, sunken ship in Langayen Gulf during the invasion of Luzon in the Philippines in January, 1945; on the staffs of Baptist and Charity hospitals and Touro Infirmary; died in Veterans Administration Hospital May 5, aged 44, of subdural hematoma and bronchopneumonia.

Garvin, Albert Henry ⊕ Buffalo; born in Joliet, Ill., in 1881; Yale University School of Medicine, New Haven, 1903; an Associate Fellow of the American Medical Association; member of the American College of Chest Physicians, American Trudeau Society, and the American Clinical and Climatological Association; president of the Buffalo and Erie County Tuberculosis Association; consultant in tuberculosis at Millard Fillmore Hospital; at one time physician in charge of the New York State Hospital for the Treatment of Incipient Pulmonary Tuberculosis at Ray Brook, N. Y., and superintendent of the Spring Hills Sanatorium in Northville, Mich.; died May 28, aged 71, of cerebral hemorrhage.

Barrera, Severo Eugene ⊕ Albany, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1929; served as professor of neurology and psychiatry at Albany Medical College and psychiatrist in chief and neurologist at Albany Hospital; formerly on the faculty of his alma mater, and principal research psychiatrist at the New York State Psychiatric Institute in New York; specialist certified by the American Board of Psychiatry and Neurology; member of the American Neurological Association, American Association of Neuropathologists, and the American Psychiatric Association; died in the Ellis Hospital, Schenectady, May 25, aged 51, of chronic cardiovascular disease.

Layman, Daniel Wunderlich ⊕ Indianapolis; born in Putnamville, Ind., June 1, 1872; Columbia University College of Physicians and Surgeons, New York, 1898; clinical professor emeritus of otorhinolaryngology at Indiana University School of Medicine; specialist certified by the American Board of Otolaryngology; member of the American Laryngological, Rhinological and Otological Society; fellow of the American College of Surgeons; served on the staffs of the Robert W. Long Hospital and James Whitcomb Riley Hospital for Children; died in Methodist Hospital April 21, aged 79, of arteriosclerotic heart disease and nephrosclerosis.

Allen, Lee Gilbert ⊕ Litchfield, Ill.; Marion-Sims-Beaumont Medical College, St. Louis, 1902; past president of the Montgomery County Medical Society; on the staff of St. Francis Hospital; died June 10, aged 75, of coronary thrombosis.

Barrett, Edward William ⊕ Medford, Mass.; Jefferson Medical College of Philadelphia, 1902; school physician; at one time city physician; on the staff of Lawrence Memorial Hospital where he died May 17, aged 82, of arteriosclerotic heart disease and bronchopneumonia.

Barthmaier, Othmar Frank, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1906; formerly on the faculty of his alma mater; served during World War I; affiliated with Hahnemann Hospital and St. Luke's and Children's Hospital, where he died May 9, aged 67, of arteriosclerosis.

Bates, George ⊕ Kingston, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1890; died in Cass City May 13, aged 91.

Baum, E. Eldon ⊕ Oklahoma City, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1928; served on the staffs of the Mercy and Wesley hospitals; died May 16, aged 56, of cerebral and kidney infarcts and bilateral tumor of adrenals.

Beeler, Bruce Henry, Evansville, Ind.; University of Louisville (Ky.) School of Medicine, 1915; served during World War I; affiliated with Deaconess Hospital and St. Mary's Hospital, where he died May 23, aged 64, of cancer and cirrhosis of the liver.

Bellak, Asher-Seelig, Philadelphia; Medico-Chirurgical College of Philadelphia, 1908; formerly affiliated with St. Agnes Hospital and the Mount Sinai Hospital, where he died May 19, aged 66, of tuberculosis.

Berger, Max Milton ⊕ Oakland, Calif.; Rush Medical College, Chicago, 1935; served during World War II; assistant chief of urology, Veterans Administration Hospital; died April 30, aged 44, of coronary thrombosis.

Carleton, Elmer Howard ⊕ Hanover, N. H.; Dartmouth Medical School, Hanover, N. H., 1897; formerly on the faculty of his alma mater; member of the New England Otolaryngological Society; served on the staff of the Dartmouth Eye Institute; in 1939 received the honorary degree of doctor of science from Bowdoin College, Brunswick, Me.; past president of the Dartmouth Medical School Alumni Association; died June 1, aged 83.

Clarke, William Thomas ⊕ Los Angeles; University of Toronto Faculty of Medicine, Toronto, Canada, 1899; L.R.C.P., L.R.C.S., Edinburgh, 1904, and L.F.P.S., Glasgow, 1904; served during World War I; an Associate Fellow of the American Medical Association; died in California Lutheran Hospital May 11, aged 75, of cerebral thrombosis.

Collins, Elmer E. G. ⊕ Chicago; Jenner Medical College, Chicago, 1910; formerly chief physician for Swift & Company, packers; died May 16, aged 68, of coronary thrombosis.

Colthorp, Ralph Weldon, Dallas, Texas; University of Texas School of Medicine, Galveston, 1942; specialist certified by the American Board of Psychiatry and Neurology; lieutenant in the U. S. Navy from 1942 to 1947; formerly director of the Boys Industrial School in Topeka, Kan.; consulting psychiatrist for the city school system; director of the Child Guidance Clinic; died May 25, aged 35, of septicemia.

Connell, John ⊕ Jersey City, N. J.; New York Homeopathic Medical College and Hospital in New York, 1889; died in the Medical Center April 1, aged 87, of bronchopneumonia.

Cooper, Jacques ⊕ Chicago; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1917; affiliated with Holy Cross Hospital; died May 9, aged 62, of heart disease.

Cress, Peter Joseph ⊕ Marysville, Calif.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1908; died in Garmisch, Germany, May 30, aged 70, of coronary occlusion.

Cummings, Joseph Leo ⊕ Poughkeepsie, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1934; specialist certified by the American Board of Psychiatry and Neurology; served during World War II; formerly member of

⊕ Indicates Member of the American Medical Association.

the city board of health; neuropsychiatrist consultant, Veterans Administration Hospital in Castle Point; affiliated with St. Francis and Vassar Brothers hospitals; died May 28, aged 45, of metastatic carcinoma of the liver.

Duckworth, William Henry ⊕ St. Clair, Mo.; National University of Arts and Sciences Medical Department, St. Louis, 1918; died in the Jewish Hospital May 3, aged 58, of heart disease.

Eckhardt, Peter, Rock Island, Ill.; Rush Medical College, Chicago, 1896; died in St. Anthony's Hospital May 9, aged 92.

Epstein, William George ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; formerly on the faculty of Loyola University School of Medicine; member of the senior surgical staff, St. Bernard's Hospital, where he died June 16, aged 65, of myocardial infarction.

Erskine, James Pendleton, Lake Worth, Fla.; Columbia University College of Physicians and Surgeons, New York, 1903; formerly practiced in New York, where he was affiliated with New York Hospital, New York Eye and Ear Infirmary, and the French Hospital; died in West Palm Beach, May 25, aged 78, of cancer.

Evans, Samuel Davidson ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1925; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology; instructor in ophthalmology at his alma mater; affiliated with Eye and Ear Hospital; died in St. Joseph's Hospital June 1, aged 51, of pneumonia and ulcerative colitis.

Harris, Henry, New York; Fordham University School of Medicine, New York, 1917; died recently, aged 59, of coronary occlusion.

Hasking, Arthur Perry ⊕ Jersey City, N. J.; Columbia University College of Physicians and Surgeons, New York, 1903; past president and secretary of the Hudson County Medical Society; member of the American Psychiatric Association; for many years county physician; affiliated with Medical Center of Jersey City; died in Monmouth Memorial Hospital in Long Branch, May 29, aged 72, of cerebral hemorrhage and hypertension.

Haworth, Dillon Benjamin, Kansas City, Mo.; Kansas City (Mo.) Medical College, 1901; served during World War I; died May 22, aged 80.

iller, Frank Brooks ⊕ Pinckneyville, Ill.; St. Louis College of hysicians and Surgeons, 1910; owner of a hospital bearing his name; died in Veterans Administration Hospital in Marion, May 6, aged 71, of coronary thrombosis.

Hirst, Virginius Bitzer ⊕ New York; University of Virginia Department of Medicine, Charlottesville, 1918; associate clinical professor of otorhinolaryngology at Post Graduate Medical School of the New York University-Bellevue Medical Center; served during World War I; fellow of the New York Academy of Medicine and American College of Surgeons; affiliated with New York Eye and Ear Infirmary; died May 9, aged 61.

Hoenes, Andrew John ⊕ Salt Lake City, Utah; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1889; an Associate Fellow of the American Medical Association; died May 29, aged 91, of arteriosclerotic heart disease.

Hoenig, Edward J. ⊕ New York; Cornell University Medical College, New York, 1910; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; consulting gynecologist, and for two terms president of the medical board, Jewish Memorial Hospital; died May 3, aged 70, of coronary thrombosis.

Holt, Charles Scott ⊕ Fort Smith, Ark.; St. Louis University School of Medicine, 1906; fellow of the American College of Surgeons; affiliated with St. Edward's Hospital and Sparks Memorial Hospital, where he died June 7, aged 72, of carcinoma of the prostate.

Kidd, James William, Fort Wayne, Ind.; Baltimore University School of Medicine, 1897; died in the Methodist Hospital May 29, aged 78, of arteriosclerotic heart disease.

Kissel, Julius Peter ⊕ Centralia, Ill.; St. Louis University School of Medicine, 1910; served during World War I; died June 3, aged 63, of cerebral hemorrhage.

Kopelowitz, Jonas Clarence ⊕ Los Angeles; Washington University School of Medicine, St. Louis, 1913; specialist certified by the American Board of Internal Medicine; served during World War I; affiliated with Cedars of Lebanon Hospital; died May 4, aged 60, of hypertensive heart disease.

Kosciolek, Stephen Frank ⊕ Lowell, Mass.; Boston University School of Medicine, 1934; drowned in Northwood Lake, N. H., April 30, aged 45.

Kroll, Louis Joseph ⊕ Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1936; died in Johns Hopkins Hospital, recently, aged 39, of glomerulonephritis.

Laessle, Henry Adolph ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1902; also a graduate in pharmacy; specialist certified by the American Board of Otolaryngology; assistant professor of otolaryngology at Graduate School of Medicine, University of Pennsylvania; member of the Philadelphia Laryngological Society; died May 13, aged 80, of coronary thrombosis.

Lamb, Gerald E., Farwell, Mich.; Detroit College of Medicine, 1899; for many years county coroner; president of the Farwell State Savings Bank; died in the Henry Ford Hospital, Detroit, May 28, aged 76.

Lange, Sidney, Cincinnati; Medical College of Ohio, Cincinnati, 1903; professor emeritus of radiology, University of Cincinnati College of Medicine; specialist certified by the American Board of Radiology; member and past president of the American Roentgen Ray Society; affiliated with Good Samaritan, St. Mary's, and Cincinnati General hospitals; died in Jewish Hospital May 9, aged 72, of cerebral hemorrhage following a fall.

Levine, Emanuel ⊕ Elizabeth, N. J.; University of Vermont College of Medicine, Burlington, 1938; served during World War II; died May 8, aged 37, of injuries received in an automobile accident.

Lewis, Harry Samuel ⊕ Washington, D. C.; George Washington University School of Medicine, Washington, D. C., 1910; fellow of the American College of Surgeons; died May 14, aged 72, of coronary thrombosis.

Lichtenwalner, Howard Adams ⊕ Bloomsburg, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1921; served during World War I; on the staff of the Bloomsburg Hospital, where he died May 12, aged 57, of cerebral vascular encephalopathy.

Light, Ralph Allison, Chanute, Kan.; University Medical College of Kansas City, Mo., 1898; veteran of the Spanish-American War; formerly secretary of the state board of registration and examination; for many years county coroner; retired surgeon of the Santa Fe Railroad; formerly member of the city council and school board; died in Neosho Memorial Hospital, June 3, aged 80, of hypostatic pneumonia.

Loefflad, Paul Aloysius ⊕ Upper Darby, Pa.; Georgetown University School of Medicine, Washington, D. C., 1925; physician for many years of Villanova (Pa.) College; on the staff of the Fitzgerald Mercy Hospital in Darby, and Misericordia Hospital in Philadelphia, where he died May 18, aged 51, of bleeding duodenal ulcer.

Long, Homer Garrison, Copley, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897; died May 20, aged 80.

Lorenzo, Frank Alexander ⊕ Punxsutawney, Pa.; Columbia University College of Physicians and Surgeons, New York, 1904; fellow of the American College of Surgeons; consulting surgeon, Elk County General Hospital, Ridgway, and the Adrian Hospital; died May 30, aged 72.

Love, Travis Drennon, Mendenhall, Miss.; Birmingham Medical College, 1915; died May 25, aged 67.

Marston, Charles Benjamin, San Rafael, Calif.; Hahnemann Medical College of the Pacific, San Francisco, 1908; past president of the board of education; on the staff of the San Rafael General Hospital, where he died May 19, aged 79, of cerebral accident and Parkinson's disease.

Martin, George Henry, Chicago; Northwestern University Medical School, Chicago, 1905; died June 27, aged 69.

Martinek, Jaroslav ⊕ Phoenix, Ariz.; University of Illinois College of Medicine, Chicago, 1946; died in Los Angeles May 28, aged 34, of bilateral pneumothorax and bronchial asthma.

Metzger, Karl Fenton, Belmar, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1933; died in Fitkin Memorial Hospital, Neptune, April 28, aged 45.

Mitchell, Allie Long, East Aurora, N. Y.; University of Buffalo School of Medicine, 1898; died in a Buffalo nursing home May 30, aged 97, of coronary thrombosis.

Nachtigall, Hans W., Chicago; Chicago College of Medicine and Surgery, 1913; for many years on the staff of St. Joseph Hospital; died May 24, aged 65, of coronary thrombosis.

O'Connor, Donald Charles ⊕ Buffalo; University of Buffalo School of Medicine, 1922; superintendent of the Edward J. Meyer Memorial Hospital, where he died May 25, aged 56, of hypertensive cardiovascular disease.

O'Donnell, John Joseph ⊕ Erie, Pa.; College of Physicians and Surgeons, Baltimore, 1904; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; served during World War I; affiliated with Hamot and St. Vincent's hospitals; died May 29, aged 70, of carcinoma.

Owen, William Arthur, Columbus, Ohio; Ohio Medical University, Columbus, 1897; died April 15, aged 78, of coronary thrombosis.

Pettit, James Kenneth ⊕ Atlanta, Ga.; Atlanta Medical College, 1914; served in France and Scotland during World War I; affiliated with the Veterans Administration; formerly on the staffs of the Georgia State Hospital for Insane in Milledgeville, Letchworth Village in Thiells, and Mansfield State Training School in Mansfield Depot, Conn.; died in Veterans Administration Hospital, Augusta, May 22, aged 63, of carcinomatosis.

Pinson, Fred Edward, Vicksburg, Miss.; Meharry Medical College, Nashville, Tenn., 1915; died May 26, aged 63, of injuries received in an automobile accident.

Plamondon, James Dillon, Lake Grove, Ore.; Willamette University Medical Department, Salem, 1898; served during World War I; formerly assistant superintendent of the Eastern Oregon State Hospital in Pendleton and Oregon State Hospital in Salem; served on the medical examining board of the Veterans Administration in Portland; died in Veterans Administration Hospital, Vancouver, Wash., May 15, aged 76, of a cerebrovascular accident.

Porter, MacGuyer ⊕ Elnora, Ind.; Eclectic Medical Institute, Cincinnati, 1897; died May 12, aged 85, of angina pectoris.

Posner, Benjamin Herman, Boston; Middlesex College of Medicine and Surgery, Cambridge, Mass., 1935; served during World War II; died April 5, aged 43, of coronary disease.

Praglin, Daniel Frank, Monterey Park, Calif.; Tulane University of Louisiana School of Medicine, New Orleans, 1929; served during World War II; died May 15, aged 49, of coronary thrombosis.

Pugh, Thomas Bryan, Napoleonville, La.; Charity Hospital Medical College, New Orleans, 1875; for many years coroner and sheriff of Assumption Parish; died May 4, aged 99.

Reilly, Maurice John ⊕ Arthur, Ill.; Chicago Medical School, 1931; served during World War II; died May 21, aged 47, of a heart attack.

Renaud, Joseph Edward ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, 1927; medical director of the Easy Washing Machine Corporation; member of the Industrial Medical Association; affiliated with St. Joseph's Hospital, where he died May 9, aged 48, of cerebral hemorrhage.

Richmond, Oscar Lee, Corbin, Ky.; Vanderbilt University School of Medicine, Nashville, 1917; died May 27, aged 58.

Roberts, Daniel Stillwell, West Point, Ky.; Kentucky School of Medicine, Louisville, 1905; local surgeon for the Illinois Central Railroad; died May 18, aged 80, of diabetes mellitus.

Roberts, William James, Logansport, Ind.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1895; died in St. Joseph Hospital March 14, aged 81, of coronary occlusion.

Scott, Walter Sidney ⊕ Denver; Columbian University Medical Department, Washington, D. C., 1896; died March 6, aged 78.

Seitz, George William, Buffalo; University of Buffalo School of Medicine, 1902; died May 6, aged 77.

Shay, Francis Leo ⊕ New Haven, Conn.; Tufts College Medical School, Boston, 1925; member of the American Academy of General Practice; affiliated with Grace Unit, Grace-New Haven Community Hospital and Hospital of St. Raphael, where he died April 24, aged 53, of coronary thrombosis and virus pneumonia.

Sheridan, Joseph Morton, Baton Rouge, La.; Fordham University School of Medicine, New York, 1910; served during World War I; formerly affiliated with the New York City Farm Colony, West New Brighton, Staten Island, N. Y., New York City Cancer Institute Hospital, Welfare Island, New York, Morrisania and Gouverneur hospitals in New York; died May 4, aged 64.

Starzynski, Theophilus A., Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1904; served during World War I; died June 9, aged 73.

Stevenson, Benjamin J. ⊕ Sparta, Ill.; Homeopathic Medical College of Missouri, St. Louis, 1898; died March 8, aged 78, of carcinoma of the prostate.

Stuart, Clyde George ⊕ Los Angeles; College of Medical Evangelists, Loma Linda and Los Angeles, 1938; certified by the National Board of Medical Examiners; public health physician with county health department for many years; affiliated with White Memorial Hospital; died May 8, aged 49, of hypertensive heart disease.

Summers, Charles Raymond ⊕ Oak Park, Ill.; University of Illinois College of Medicine, Chicago, 1929; affiliated with West Suburban Hospital; died in Veterans Administration Hospital, Hines, June 11, aged 55, of chronic glomerulonephritis with uremia.

Tillotson, Harry Trudeau, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1886; died June 15, aged 89, of coronary insufficiency.

Tittle, Lloyd Clay ⊕ Dallas, Texas; Baylor University College of Medicine, Dallas, 1918; died May 6, aged 61, of surgical shock with acute hepatic insufficiency.

Vander Bogart, Harry Eugene ⊕ Goshen, Ind.; the Hahnemann Medical College and Hospital, Chicago, 1914; served during World War I; member of the board of directors of the Goshen Hospital; died May 23, aged 68, of carcinoma of the ascending colon.

Voorhis, Anna E. Harvey ⊕ Mount Vernon, N. Y.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1893; formerly practiced in Yonkers, where she was affiliated with St. John's Hospital; died June 9, aged 85, of hypertensive arteriosclerotic disease.

West, Edward W., North Little Rock, Ark.; University of West Tennessee College of Medicine and Surgery, Memphis, 1904; died in the Provident Hospital, Chicago, May 25, aged 76, of cerebral hemorrhage and essential hypertension.

Wiener, Jacob Jesse ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1916; member of the American Academy of Pediatrics; affiliated with Hospital for Joint Diseases; died in Miami Beach, Fla., May 26, aged 58, of carcinoma of the colon.

Winne, William Ray ⊕ North Syracuse, N. Y.; Syracuse University College of Medicine, 1917; served during World War I; formerly county coroner; affiliated with Crouse Irving Hospital in Syracuse; died May 28, aged 61, of coronary disease.

GOVERNMENT SERVICES

ARMY

Lieut. Hopkins Awarded Soldier's Medal.—First Lieut. William C. Hopkins of Chicago, medical officer with the 25th Infantry Division in Korea, has been awarded the Soldier's Medal for "unselfish heroism and dauntless courage." The citation reads in part as follows: "On March 7, 1952, a helicopter crashed while attempting to evacuate two wounded soldiers from a foggy, windswept hill position near Sohuiri, Korea. With utter disregard for his personal safety, Lieutenant Hopkins ran through a known mine field to the crashed helicopter and aided in righting the flaming aircraft, rescuing one of the wounded soldiers and attempting to free the other man still trapped in the wreckage. He persisted in his efforts until the heat became unbearable and he was forced to move away from the craft.

"The helicopter pilot dashed into the flaming wreckage and tried again to rescue the trapped man. Realizing that the gas tank would soon explode, Lieutenant Hopkins ran into the inferno and forced the pilot away from the craft, saving him from permanent disfigurement and possible death. Lieutenant Hopkins' unselfish heroism and dauntless courage are in keeping with the highest traditions of the United States Army."

Lieutenant Hopkins is the son of Percy E. Hopkins, M.D., of Chicago, a former president of the Illinois State Medical Society.

DEPARTMENT OF DEFENSE

Korean Society News.—Col. Walter M. Bartlett, Decatur, Ga., Medical Consultant at Eighth Army Headquarters, has been elected president of the "38th Parallel Medical Society of Korea," and Capt. Inger Schulstad, a woman doctor with the Norwegian Surgical Hospital, secretary. They succeed Lieut. Col. Charles E. Mason, Alhambra, Calif., I Corps surgeon, the outgoing president, and Capt. Ruth Dickson, Vinton, Va., chief nurse of the 8,055th Mobile Army Surgical Hospital, former secretary.

The new vice-presidents are Col. Erling F. Hjort, commanding officer of the Norwegian Surgical Hospital; Col. Morgan Smith, Canada, newly-appointed surgeon of the First Commonwealth Division; Capt. Louis Kirkpatrick, USN, Reagan, Texas, First Marine Division Surgeon; Lieut. Col. Claude B. Knight, Wewoka, Okla., 45th Division Surgeon; Lieut. Col. Sin Jai Kuh, commanding officer of the 5th Republic of Korea Mobile Army Surgical Hospital; Lieut. Col. A. G. Rangaraj, commanding officer of the 60th Indian Field Ambulance Unit, and Lieut. Col. H. Haskell Zipperman, Mount Holly, N. J., commanding officer of the 8,063d Mobile Army Surgical Hospital. This unique society, which is composed of medical personnel in I Corps and adjacent IX Corps areas, meets twice a month on the 38th parallel. Speakers at the most recent meeting were Colonel Hjort of the Norwegian Hospital and Capt. Edward Jahnke, Pittsburgh, Pa., from Walter Reed Army Hospital, Washington, D. C.

VETERANS ADMINISTRATION

New GI Bill for Veterans.—The President has signed a new GI Bill for veterans who served in the armed forces any place in the world since the start of the Korean conflict on June 27, 1950. The new law provides five benefits, all designed to assist veterans in their return to civilian life. The benefits include education and training; guaranteed or insured loans for homes, farms, and businesses; unemployment compensation; mustering-out pay; and job finding help.

The education and training provisions allow a veteran one and one-half days of training for each day in service after the outbreak of the Korean fighting, regardless of where the service was performed, up to a maximum of 36 months; however, veterans who have previously trained under earlier veterans' training laws, the World War II GI Bill or Public Laws 16 or 894 for the disabled, may get up to 48 months, minus whatever time they have already spent in training under those earlier programs. A veteran may train in school or college, on the job or on the farm, as long as the school or training establishment has been approved by an appropriate state approving agency and meets other qualifications of the law.

Veterans in GI Bill training will receive an education and training allowance each month from the government to meet part of the expenses of their training and living costs. Tuition, fees, books, supplies, and equipment will not be paid by the government; instead, they will be paid out of the monthly allowance. Rates for veterans in full-time training in schools and colleges are $110 a month if they have no dependents, $135 if they have one dependent, and $160 if they have more than one dependent. Those in training less than full time will receive lower monthly rates. Top monthly amounts for on-the-job trainees are $70 without dependents, $85 with one dependent, and $105 with more than one dependent. The maximal allowances for institutional on-farm trainees are $95, $110, and $130, respectively. The law requires that on-job and on-farm rates be reduced, at four month intervals, as the training progresses and the veteran's own earnings increase. Veterans were reminded that the last three benefits of the new GI Bill, unemployment compensation, mustering-out pay, and job-hunting aid, are not administered by the Veterans Administration. Veterans should not write to the VA about them if they want further information or have questions to be answered; instead, they should correspond directly with the agency concerned. Education and training, for post-Korea veterans, must be started by Aug. 20, 1954, or two years after release from active duty, whichever comes later. No training may be given beyond either seven years after discharge or seven years after the end of the current emergency, whichever is later.

MISCELLANEOUS

Science Foundation to Compile Research Information.—Federal agencies supporting scientific research and development programs have been asked to supply the National Science Foundation with statistical and fiscal information about their programs for the fiscal years 1951 and 1952. The foundation is compiling such information at the request of the Bureau of the Budget, which has gathered similar information in previous years. The final report, which it is hoped will be available before Jan. 1, 1953, will be of value also to Congress and to the agencies, themselves, in the administration and planning of their programs. The information will be of value to the foundation, also, in fulfilling its statutory responsibilities with respect to scientific research and its studies concerning the effect of present support and policies on research and education in the institutions of the country.

The information will be compiled under various functional classifications, including basic research, applied research, development, and increase of research and development plant, and subject classifications including biologic, medical, agricultural, physical, mathematical, engineering, and social sciences. Typical examples of nonprofit institutions for which information will be gathered are colleges and universities, research institutes, research foundations, experiment stations, hospitals, libraries, museums, observatories, and corporations organized specifically to do scientific research and development for the federal government on a nonprofit basis. Information on direct research activities of agencies of the federal government will be excluded, but the report will include information on federal support to agencies of state, local, or foreign governments.

FOREIGN LETTERS

BRAZIL

Colon Resection with Immediate Open Anastomosis.—Dr. E. da Silva Bastos, professor of surgery at the São Paulo State University, recently reported a series of 72 patients on whom he performed resection of the colon followed by immediate open anastomosis. Except for four of the cases, two with tuberculomas of the cecum and two with inflammatory strictures from diverticulitis, all were due to cancer of the colon, the cecum, and the rectum. In the 72 cases, 12 with Mikulicz resection, 23 with closed anastomoses, and 37 with open anastomoses, there were four deaths (5.53%), one from generalized peritonitis after an ileocolic closed anastomosis, one from hypoproteinemia as a consequence of a hematoma, one from uremia, and one from cerebral thrombosis. In the cases in which closed anastomosis was performed there was one death (4.35%), and in the cases with open anastomosis there was also one death (2.70%). There were 5 complications in 12 cases of resection by the Mikulicz technique, the most frequent of which were abscesses of the intestinal wall and eventrations. In only one case of eventration was there no accompanying subcutaneous abscess. In the group of closed anastomoses, the most frequent complication was stricture, which occurred in five cases and probably also in two cases of dehiscence of the suture with abscess or fecal fistula. Closed anastomosis, used in two cases of resection of the rectum, caused stricture with fecal fistula in both. In one of the cases, the fistula was very wide, remaining so until the death of the patient 18 months after the operation. Open anastomosis, used in 16 cases without colostomy, caused fewer complications. There were four cases of fecal fistula, all of them in previous resections of the rectum. All fistulas were of little importance, disappearing spontaneously within a short time. Only one fistula occurred in a patient without colostomy; in the other three patients a minimal colostomy had been done. The author concludes that the open anastomosis is superior to the closed anastomosis for the following reasons. 1. It is a simpler technique, not needing special instruments. 2. The suture is easier; the stitches are made directly through the walls of the intestine under direct vision. 3. The suture is tighter and the approximation of the intestinal layers more perfect.

Hemagglutination with Human Red Blood Cells and BCG Tuberculin.—Dr. Laerte de Andrade, of the Oswaldo Cruz Institute, and Dr. Candido Silva, of the division of leprosy, National Department of Health, have just reported the results of their extensive investigations on the hemagglutination test of Middlebrook and Dubos and its use in connection with tuberculosis and leprosy. In the introduction of their report the authors state that, owing to the difficulty of obtaining in Brazil specific antigens prepared with the polysaccharide fraction of the tubercle bacillus or the Lederle tuberculin (O.T.) recommended by American investigators, they tried to use several tuberculin preparations made in the country. The only one that gave good results was prepared by cultivation of BCG on a Sauton medium. The authors performed 271 tests on serums from blood donors as well as from tuberculous and leprous patients. Human O Rh-negative red blood cells sensitized by BCG tuberculin were used for the test. A qualitative test very useful for routine work was performed in capillary tubes, as an adaptation of Chown's test for Rh antibodies.

The 271 serums examined included 68 from tuberculous patients, 116 from leprous patients, and 87 from donors from the blood bank of the Rio de Janeiro Hospital dos Servidores. There were 16 negative serums (23.5%) among the tuberculous patients, 22 (18.9%) among the leprous patients, and 82 (94.3%) among healthy blood donors. Of the 52 tuberculous patients with positive results, 19 showed results with titers of 1:32 or less and 33 showed results with titers from 1:64 to 1:1024. Of the 94 leprous patients with positive results, 40 showed results with titers 1:32 or less and 54 showed results with titers 1:64 to 1:1024. Of the 87 blood donors, only 5 showed positive results (3 with a titer of 1:4, one with a titer of 1:8, and one with a titer of 1:16). The 116 leprous patients included 11 of the undetermined form, 15 of the tuberculoid form, and 86 of the lepromatous form. Of the latter, 43 patients had active leprosy and 43 were in clinical regression, without bacilli in the nasal mucus and in the skin, and were scheduled to be transferred to the outpatient department. Among the patients with the lepromatous form in clinical regression, 14 showed negative results of the hemagglutination tests, and many of the others had very low positive agglutination titers. Three of them, however, had very high titers (1:256 and 1:1024). The authors explain these results as being caused by visceral leprosy, which probably did not show a regression similar to that of the tegumentary forms. In this connection, the authors' conclusion is that the Middlebrook-Dubos test is useful in supplying some indispensable information as to the course of the disease in patients with the lepromatous form and especially of candidates for transferral to the outpatient department.

Milestone in Campaign Against Yellow Fever.—A milestone has been reached in 1951 in the campaign against yellow fever in Brazil: the complete eradication of Aedes aegypti, the urban vector of the disease. A recheck is being made, however, in some parts of the eastern and northeastern regions, where the environmental conditions are very favorable to that species of mosquito, although the work done during the first five months of the current year in those areas has supposedly eradicated the mosquito. There still must be careful and continuous inspections in order to prevent the reimportation of the mosquito through the borders, and air and maritime ports, since A. aegypti still exists in 23 countries and possessions and colonies in the Americas.

The sylvan form of yellow fever is transmitted through other species of mosquitos. The last three cases of urban yellow fever were reported in 1937, and after this only the sylvan form of the disease was recorded in Brazil. During the three 5 year periods 1937-1941, 1942-1946, and 1947-1951 there were, respectively, 807, 141, and 45 cases of the disease. The campaign against the sylvan form of yellow fever includes mainly vaccination, viscerotomy, and laboratory examinations. About 900,000 persons were immunized against yellow fever in 1951, bringing the total number of vaccinations, since 1937, to more than 7 million. Immunization is mainly used to protect persons who have to work or live in forests. Viscerotomy is the best resource for the discovery of the silent foci of the disease in areas in which it frequently goes unrecognized even by trained physicians. There were, in 1951, a total of 1,324 localities with viscerotomy service, which sent 8,185 specimens of liver to be examined in the laboratory.

DENMARK

Civil Defense and Biologic Warfare.—In 1951 the governing body of civil defense requested the Danish public health authorities to compose a memorandum on civil defense problems connected with biologic warfare. In December of that year, the public health authorities appointed a committee of bacteriological, epidemiological, clinical, and administrative experts to pre-

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

pare such a memorandum. The completed memorandum is concerned with successfully combating the results of biologic warfare. The sources of information that the committee used are official publications and are available to all persons interested. The memorandum refers, of course, particularly to conditions that exist or may develop in Denmark. The authors conclude that biologic warfare is possible in theory and feasible in practice, although its effects cannot be calculated with certainty. They also conclude that though biologic weapons can be directed against military objectives, their employment undoubtedly greatly endangers civilians. Panic among civilians may be the only effect sought by an aggressor anxious to demonstrate his strength and to threaten the government of an enemy country. The possibilities for sabotage with biologic weapons are almost unlimited, and the fifth columnist can do his work with greater accuracy and with fewer weapons than a regular combatant. Many germs can be cultivated in great quantities under primitive conditions in secrecy in the country to be attacked. In Denmark an attack with infected insects is not likely to be successful owing to its climate and its indigenous insects, but yellow fever and rickettsia may be conveyed not only by insects but also by inhalation. The weight and volume of biologic weapons are so small that it may be impossible to prevent their entry into a country by smuggling. For this and various other reasons, attention must be focused on preventing the effects once such warfare has started. In Denmark there are not enough vaccines for vaccinating all persons in a community against all the diseases spread in biologic warfare, but it should be possible to produce a botulinus vaccine suitable for limited and much exposed sections of the community. The prophylactic employment of antibiotics presupposes enormous quantities of them, and they would have to be limited to sections of the community greatly exposed to infection. Penicillin and the sulfonamides are now produced in Denmark in sufficient quantities for an emergency of limited duration, but the cost of well-known antibiotics produced abroad is prohibitive.

Protests Against Wholesale Legal Abortions.—The Hippocratic attitude towards the induction of abortion has lately been defended by Prof. Erik Rydberg, in whose hospital abortions are induced only on strict and clear medical indications. Writing in the organ of the Danish Medical Association, *Ugeskrift for Laeger,* for May 22, he reports that the number of legally induced abortions has risen considerably since the adoption of the abortion law in 1937 and its practical application after 1939. Between 1940 and 1950 the number of legal abortions has risen from 522 to 3,969. It is calculated that in Copenhagen in 1951 the legal abortions were equivalent to 12% of all the confinements in this year. The annual reports of gynecologic hospitals suggest that most legal abortions are indicated by psychiatric considerations. For example, at the gynecologic department of the Frederiksberg Hospital in 1950 the 319 legal abortions included 267 induced on psychiatric grounds.

Declining Tuberculosis Rate in Childhood.—Several articles in the medical press have lately asked the reason for the tuberculosis morbidity declining more rapidly at the school age than at the preschool and postschool ages. They also wondered whether BCG vaccination offers any answer to this question. Dr. E. Groth-Petersen, who is in charge of the tuberculosis dispensary work of the County of Praestö, has studied the characteristics of tuberculosis in his district since a tuberculosis dispensary was started there in 1943. Between then and 1951 there was no great decline in the tuberculosis morbidity at the preschool age, at which BCG vaccination is comparatively rare. On the other hand, at the school age, from 7 to 14 years, the tuberculosis morbidity showed an abrupt fall, which has been maintained since 1947. Between the ages of 15 and 19 there was a more gradual fall. Practically every schoolchild found to be tuberculin-negative was vaccinated with BCG after 1943. After discussing the possibilities that the decline of the tuberculosis morbidity might be due to less exposure to infection or to changes in diagnostic standards or to other factors, Dr. Groth-Petersen concludes that the abrupt fall in the tuberculosis morbidity between the ages of 7 and 14 years can largely be explained as the outcome of wholesale BCG vaccination in school.

In another study, Dr. Jörgen Kringelbach compared the tuberculosis clientele of a children's hospital in the two years 1940 and 1950. This hospital, the only one of its kind in Denmark, dealt with tuberculous children from Copenhagen. Its 47 beds were, for many years, always in use for tuberculous patients, but of late most of them have been allocated to nontuberculous patients for want of enough tuberculous children. In the two years under review there was little difference in the number of preschool children, whereas there was a marked drop in the number of children of the school age, 7-14 years. The relative scarcity of the school age patients in 1950 is held by Kringelbach to be largely due to the extensive BCG vaccination of Copenhagen's tuberculin-negative school children in 1948 and 1949. There was a marked difference between the two years 1940 and 1950 with regard to the duration of hospitalization, which was 100 days on the average in 1940 as compared with only 62 days in 1950. The character of the disease was on the whole less serious in 1950 than in 1940 to judge by the radiological findings, the temperature, and the erythrocyte sedimentation rate. Thus in the brief span of 10 years a profound change had come over the clientele of this hospital.

PARIS

Iodochlorhydroxyquin in Experimental Tuberculosis.—P. E. David and F. Tisson reported to the National Academy of Medicine the first in vivo trials against tuberculosis of an iodochlorhydroxyquin suspension. Two groups, of 10 animals each, were inoculated with a human virulent strain of tuberculosis. At the end of three weeks one group was treated by daily subcutaneous administration of 3 cg. per kilogram of body weight of the drug while the other served as untreated controls. Eight weeks after the inoculation one guinea pig was killed in each group, the others being killed at intervals within the following 15 days. The results of the autopsy of these animals revealed that of the 10 animals who were given iodochlorhydroxyquin, 7 showed only lymph node involvement of the ganglions (stage 1), 1 an involvement of lymph nodes and spleen (stage 2), and 2 an involvement of lymph nodes, spleen, and liver (stage 3); none of these animals reached stage 4 (lymph nodes, spleen, liver, and lungs involved). On the other hand, of the 10 untreated control animals, 5 were in the disease stage 4, 1 in stage 3, and 4 in stage 2. None of the control animals remained in stage 1. Swabs of inguinal abscesses showed the presence of a larger number of bacilli in all control animals than in the treated group.

Microbial Substitution and Selection in Chronic Infections.—The failure of some therapy with antibiotics has been explained by the resistance acquired by bacteria in the course of treatment. It has also been found, in other cases, that the organism sets off a mechanism of the adaptation enzymes; for instance, penicillinase undergoes a morphological change, taking either the dwarf or the L form, according to Tulsane. J. Brissou of the French navy, on the basis of clinical and laboratory observations, noted that after a patient is treated with an antibiotic a relapse may occur after a transient improvement and the disease may become chronic. A further examination reveals new bacterial flora. There is a substitution of bacteria, and it is noted that, in this selection, resistant species are present. The author noted the substitution in urine of proteins or Klebsiella by Escherichia coli, of Proteus by enterococci and, in urethritis the substitution of streptococci by gonococci. In an unpublished work done in collaboration with Ardisson, the author show that, after massive doses of an antibiotic, the rich intestinal flor decreases and there is an upset of the bacterial equilibrium accompanied by new disorders, notwithstanding the eliminatio of Salmonella or Shigella. The author suggests a new idea the cause of chronic diseases by selection and substitution bacteria.

CORRESPONDENCE

PATIENTS WITH POLIOMYELITIS

To the Editor:—I have read with interest the article entitled "Home Care of Patients with Acute Poliomyelitis" by Philip M. Stimson, M.D., published in THE JOURNAL (June 21, 1952, page 719). There is no question but that the emotional attitudes of the family and patient are important. Hospitalization in many instances is unnecessary, and long periods of transportation are detrimental; however, I do feel it necessary to comment on some other considerations.

In the recognizable case without paralysis, it is well known that the severity of the early signs and symptoms bears no direct relationship to prognosis in regard to either life or developing weakness. Also, changes in the patient's condition can develop rapidly, and, if the patient is hospitalized, appropriate measures can be immediately instituted. However, if the patient is at home, the attendant may not notice the signs, the physician may not be located promptly, and the transportation to the hospital occur at a most inappropriate time from the point of view of the patient's welfare.

In some areas private duty nurses are scarce, and, if the patient remains at home, his care will be the responsibility of nonmedical attendants. If a diagnosis is made late in the disease, when the temperature is returning to normal and care is adequate, home care has advantages. However, we are preaching early diagnosis, and it would seem that the lack of relationship between early signs and symptoms and prognosis would indicate that hospitalization in early cases is preferable.

EOSINOPENIC RESPONSE TO EPINEPHRINE

To the Editor:—It is unfortunate that so many investigators, such as Drs. Charles W. Dowden and James T. Bradbury (Eosinophil Response to Epinephrine and Corticotropin: Studies in Alcoholics and Nonalcoholics, *J. A. M. A.* **149**:725-728 [June 21] 1952) continue to use subnormal eosinopenic response to injection of epinephrine as a means of testing pituitary-adrenal function.

In 1950, on the basis of animal investigations, Thorn and his associates (Recant, Hume, Forsham, and Thorn: Studies on the Effect of Epinephrine on the Pituitary-Adrenocortical System, *J. Clin. Endocrinol.* **10**:187, 1950) postulated that the hypothalamus, pituitary, and adrenal cortex are successively stimulated to produce epinephrine eosinopenia. Thorn and Forsham wrote that ". . . a fall of 50% or more in circulating eosinophils (after injection of epinephrine) excludes the presence of serious pituitary A.C.T.H. or adrenal cortical insufficiency," (Thorn and Forsham: Clinical Tests for Adrenal Cortical Reserve, in Progress in Clinical Endocrinology, Soskin, S., editor, New York, Grune and Stratton, 1950, p. 213). However, a large number of physicians interpret the test erroneously. They believe that an inadequate response, i. e., of less than 50% fall, indicates disease or relative dysfunction of the hypothalamus, pituitary, or adrenal cortex.

My colleagues and I have observed greater than 50% drop of eosinophils following injection of epinephrine in patients with pituitary tumors and in patients who were subjected to adrenalectomy and who were receiving small doses of cortisone. Responses of less than 50% were seen in a large number of patients with unrelated pathological conditions (Best, Muehrcke, and Kark: Studies on Adrenocortical Eosinopenia, abstract, *J. Clin. Investigation* **30**:629, 1951; Best, Muehrcke, and Kark: Clinical and Statistical Evaluation of Four-Hour Eosinophil Response Tests, abstract, *J. Lab. & Clin. Med.* **38**:790, 1951; Muehrcke and others: Mechanisms of Adrenocortical Eosinopenia: Antagonisms Between Heparin and Cortical Hormones and the Action of Epinephrine Post-Adrenalectomy, *Proc. Inst. Med. Chicago* **19**:68, 1952. Kark and Muehrcke: Does Adrenaline Eosinopenia Reflect Pituitary Adrenal Function in Man? *Lancet* **1**:1189-1191, 1952. Best, Muehrcke, and Kark: Studies on Adrenocortical Eosinopenia: A Clinical and Statistical Evaluation of Four-Hour Eosinophil Response Tests. *J. Clin. Investigation,* to be published). These observations, together with clinical and statistical analysis of 702 four-hour response tests in 284 persons, indicate that the epinephrine test is of little value in the diagnosis of adrenal, hypothalamic, or pituitary disease; nor does it accurately assess the function of these three organs.

The verbal reports given two weeks ago at the annual meeting of the Endocrine Society indicate that injection of epinephrine into healthy persons does not produce a uniformly significant increase in urinary 17-ketosteroid excretion (Jeffries and Bochner: A Comparison of Effects of Single Injection of A.C.T.H. and Epinephrine upon Adrenal Cortical Activity) or in blood levels of 17-hydroxycortico-steroids (Nelson, Sandberg, Palmer, and Glenn: Levels of 17-Hydroxy-Corticosteroids Following Intravenous Infusion of Epinephrine into Normal Men). Our observations and these two reports indicate that the mechanisms of epinephrine-induced eosinopenia are yet obscure. Therefore, we believe the epinephrine response test should be abandoned in clinical practice, at least until the mode of action is clarified. Moreover, the test should not be used to test pituitary-adrenal activity in groups of patients. Proper assessment of functional endocrine changes in alcoholics, in schizophrenics, and in others must await assay of corticotropin and adrenal steroids in these patients.

POSTPARTUM HEMORRHAGE

To the Editor:—In THE JOURNAL of June 21, 1952, there is an article by Dr. Ernest Myller titled "Control of Postpartum Hemorrhage" (page 757). In this article I am quoted as saying it is my "belief . . . that when the first uterine packing is not successful, the uterus is probably ruptured. If such is the case, a second packing is definitely contraindicated." This is not only a complete misquote, it is also contrary to my teaching of a number of years.

The correct quotation from the source used by Dr. Myller is ". . . severe postpartum hemorrhage which does not respond to massage and the rather efficient oxytocic agents, when given intravenously, particularly when it occurs in the multigravida, is quite likely to be due to a partial or a complete rupture of the uterus. If this be present, packing will not only do no good, but will actually be harmful, in that vitally necessary time will be lost."

Actually, in our clinics at the University Hospital, Baltimore, and the Baltimore City Hospitals, the uterine pack has not been used to control postpartum hemorrhage for more than six years, representing about 30,000 consecutive deliveries. It is my belief that the uterine pack to control postpartum hemorrhage has absolutely no place in present-day obstetrics.

FUNGUS INFECTIONS

To the Editor:—In the editorial "Fungus Infections Complicating Antibiotic Therapy," which appeared in THE JOURNAL, June 21, 1952, page 762, mention is made that my co-workers and I reported six instances of pulmonary moniliasis. This notation is inserted in a paragraph in such a way that it would appear that these six instances followed the use of one of the antibiotics discussed in the article. I would like to correct this impression and note that all the patients studied had pulmonary moniliasis and received no antibiotic therapy and that each of these patients was studied in the era before aureomycin, chloramphenicol, and terramycin came into general use.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Malpractice: Drainage Tube Left in Patient Following Operation.—The plaintiff sued for damages alleged to have been caused by the malpractice of the defendant physician. The jury found in favor of the plaintiff, but the trial judge entered judgment for the defendant notwithstanding the verdict. The plaintiff therefore appealed to the Supreme Court of California.

The plaintiff consulted the defendant physician concerning a severe pain in his scrotum. The ailment was diagnosed as a varicocele, and an operation was recommended and performed by the defendant. The plaintiff told the defendant that he did not want to lose his left testicle, and the defendant said that the operation was a simple one and that if the testicle was healthy there would be no occasion for its removal. Shortly after the operation the defendant told the plaintiff's mother that the left testicle was smaller than the other one but that it appeared healthy and he had not removed it. The day following the operation the plaintiff's scrotum began to swell and become painful. The dressings had to be removed. The evidence showed that at that time the operative incision was tightly sewed and that no drainage tube protruded from it. Penicillin was administered, but the swelling continued, and about a week after the operation the defendant probed the wound with surgical forceps to establish drainage and directed the plaintiff to take sitz baths. After about two weeks he was taken home but was instructed to continue the baths and to walk as much as possible. His mother helped him with the baths and dressed the incision. About two months after the operation, while cleaning pus from the probe wound, the plaintiff and his mother noticed, deep in the wound, the edge of a substance that resembled "a muscle." When this substance was touched with the swab stick, about an inch of white rubber tube protruded. On the following morning, the rubber tube stuck to a dressing and came out. The plaintiff and his mother described it as being "very wet and full of pus." This was the first time either the plaintiff or his mother knew that a rubber tube had been inserted in his scrotum. The plaintiff immediately telephoned the defendant who said: "That is fine. I left it for a drain. I am glad you found it." The defendant then advised the plaintiff that a further operation would be necessary and that the left testicle would have to be removed. This operation was performed by the defendant assisted by Dr. Gummess, who had also assisted at the first operation. The left testicle was removed, and a drainage tube was inserted, its presence being indicated on the operative report. Several days later the drain was removed, and the plaintiff left the hospital. It was the plaintiff's contention that a rubber drainage tube had been negligently left in the incision after the first operation and that such negligence resulted in the necessity for the removal of his left testicle.

Concerning the first operation, the defendant testified that he had placed a rubber tube in the plaintiff's scrotum for drainage purposes. He described it as being attached to the wall of the scrotum by sutures, part of the tube protruding from a "stab wound" made in the lowest part of the scrotum. He admitted, however, that he told no one except Dr. Gummess of the tube. He did not tell the interns or nurses of its presence and "overlooked" mention of the tube or stab wound in making his operative report, although it called for pertinent information on drainage. When asked whether the tube might have slipped entirely inside the scrotum, the defendant replied that such was ". . . within the realm of possibility . . . ." Dr. Gummess substantiated the defendant's testimony as to the insertion of the tube but said that he did not see it at any time when he examined the patient after the operation. As a practicing specialist in urology, Dr. Gummess was asked whether ". . . in an operation for the removal of a varicocele, under proper medical and surgical practice here, would a physician and surgeon intentionally permit a wound to close, leaving a rubber tube within the scrotum, with no part of the rubber tube protruding?" He replied, "No, he would not." It was further established, by expert testimony, that drainage of scrotal wounds is a mandatory rule because "proper drainage will prevent infection." Two experts identified the pain and other symptoms of disease in the plaintiff's scrotum after the operation as "classical signs" and "indications" of infection, which indicates bacterial attack on living tissue. The defendant admitted that there was infection present in the incision that was draining and that the draining involved the testicle, the spermatic cord, and the scrotum. Such infection, he said, can cause tissue to become necrotic.

On this evidence the jury returned a verdict in favor of the plaintiff, but as previously stated, the defendant's motion for judgment notwithstanding the verdict was granted. A defendant's motion for judgment notwithstanding the verdict, said the supreme court, may properly be granted only when, disregarding conflicting evidence and indulging in every legitimate inference that may be drawn from the plaintiff's evidence, the result is a determination that there is no evidence sufficiently substantial to support the verdict. Relying on this rule, the plaintiff contended that the evidence, disregarding conflicts, and the legitimate inferences to be drawn from it furnished sufficient support for the jury's implied finding that the defendant was negligent in performing the varicocelectomy, which negligence proximately caused the subsequent removal of the testicle.

The record fully supports the plaintiff in this regard, said the Supreme Court. From the evidence presented by the respective parties, the jurors reasonably might have concluded that the rubber tube was completely enclosed within the scrotum at the time of the operation and the incision tightly sutured. If, however, they chose to believe that the defendant left the tube protruding, there is ample evidence tending to prove a failure to fasten it so as to prevent withdrawal into the scrotum, a possibility admitted by the defendant. On either view of the evidence, it shows a surgical procedure that permitted the operative incision to become tightly closed, leaving the rubber tube completely within the scrotum. One of the physician witnesses in the case testified that "It is a rule, it is a mandatory rule, that we always drain scrotal wounds . . . ." The evidence would justify a conclusion that the defendant violated this "mandatory rule" by failing to drain the scrotum during the period following surgery, either because he made no provision for drainage or because he permitted the drainage tube to slip into the scrotum and the operative incision to close completely.

There is no merit, the Supreme Court continued, in the contention that the evidence failed to establish a causal relation between the failure to properly provide for drainage and the subsequent necessity for removal of the testicle. "The law does not require that negligence of the defendant must be the sole cause of the injury complained of in order to entitle the plaintiff to damages therefor. All that is required . . . is that the negligence in question shall be a proximate cause of the injury . . . ." It was shown that at the time of the first operation the plaintiff's testicle was healthy and for that reason the defendant did not remove it. Yet, 42 days later, it was in such condition that removal was deemed necessary. Although the defendant argued to the contrary, the jury's implied finding that a causal relationship existed was not purely speculative. According to the medical testimony, the reason for the "mandatory rule" of drainage is the danger of infection. That testimony also characterized the plaintiff's symptoms after the operation as "classical signs" and "indications" of infection, and unquestionably it was a necrotic condition that necessitated the second operation.

Accordingly, the Supreme Court reversed the judgment of the trial court in favor of the defendant physician with directions to the trial court to enter judgment in favor of the plaintiff. *Champion v. Bennetts, 236 P. (2d) 155 (California 1951).*

Cardiac Arrest.—Although there has been increasing interest in cardiac arrest, its pathogenesis and the possibilities of its prevention have not received sufficient attention. The "specific tissue" of the heart has no distinguishing anatomic features, but it has the capacity to originate rhythmical contractions autonomously. It is the hardiest tissue in the body, being able to function for long periods without oxygen or even blood supply. The many sources of reflexes that could influence the specific tissue are listed, and the role of anesthesia, anoxia, vitamins of the B group, and endocrine imbalance are discussed. In 35 cases in which a wide variety of anesthetic agents and stimuli were used, 19 patients showed evidence of functional derangements in the specific tissue. At the Lahey Clinic in the last seven years there have been 14 cases of cardiac arrest of such severity as to require surgical intervention, but there must have been many less serious cases that nevertheless represent examples of a vagovagal reflex. The specific tissue that has the capacity to originate stimuli is widely distributed throughout the auricles and ventricles, but there are no vagal fibers in the ventricles. In a normal healthy heart no stimulus from any source, including the carotid sinus, can cause a general collapse, because the specific tissue in the ventricles, being free of vagal influences, can form stimuli and function autonomously. Undesirable reflexes that interfere with the specific tissue may originate in the mucosa of the respiratory or gastrointestinal tracts and in the pleura; those from the pulmonary vessels act on the coronary vessels. Anesthesia depresses the capacity of the specific tissue to form stimuli; in other words, a heart under anesthesia is as vulnerable to vagal stimulation as a heart with widespread organic disease in the specific tissue. Anoxia per se will not cause or initiate these reflexes, but its presence enormously potentiates the action of the anesthetic agent, with a still further depression of the capacity of the specific tissue to form stimuli. Vitamin B complex is important for smooth cardiac function, and in deficient nutrition its adequate use preoperatively is valuable. During endocrine imbalance, such as in the climacteric, substitution therapy is a good preoperative measure. The authors stress that the introduction of various mechanical contrivances into the respiratory or gastrointestinal passages and the clamping or tying of structures containing vagal nerve endings are not without danger, and atropine should be given. In any case in which the surgeon restores cardiac activity after a cardiac arrest, with the possible exception of ventricular fibrillation, the standstill was due to a sudden depression in the automaticity of the specific tissue following a reflex stimulus and almost certainly was preventable.

Electrocardiographic Finding in Single Ventricle Hearts.—It is generally agreed that the QRS complex of the electrocardiogram is due to depolarization of the ventricular muscle. The muscle bundles in the ventricle are those of the left ventricle, those of the right ventricle, and those of the interventricular septum. The configuration of the QRS curve depends on the relative size

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

of these muscle bundles and the direction of the wave of excitation with respect to the location of the exploring electrode. A heart with a single ventricle with either one or two atriums, can be studied electrocardiographically with respect to the ventricular complex. Freireich and Nicolson studied two patients with a single ventricle. One of these patients is still alive, and the diagnosis of single ventricle was confirmed at operation, in which a subclavian artery was anastomosed to the pulmonary artery. Necropsy in the other patient revealed true cor triloculare biatriatum, with two well-defined atriums, a single large ventricle, and a rudimentary chamber. In the fatal case, the left leg lead was the inverted mirror image of the right arm lead, while in the other case, the left leg lead showed a similar relationship with the left arm lead. This was probably due to the different electrical positions of the single ventricle in relation to the extremities. The ventricular complexes in all the leads consisted of only one or two deflections, a qR, QS, or R.

Anoxemia Test in Coronary Heart Disease.—Mathers and Levy emphasize three points with regard to the anoxemia test: 1. The test should be employed clinically only when the diagnosis is in doubt. 2. A positive result affords objective evidence of coronary insufficiency. 3. A negative result does not rule out the possible presence of coronary heart disease. In order to ascertain the prognostic value of the test, a follow-up study was made of 254 persons on whom it was performed during the decade 1937 to 1947. Included were 141 patients with manifest or suspected coronary heart disease, 10 with hypertension, and 103 with no evidence of a cardiovascular disorder. The average follow-up period was six years. Sixty-three persons died during the course of the study. In the 16 cases in which an autopsy was performed, the clinical diagnosis was confirmed. In an effort to find correlations between the result of the anoxemia test, the clinical status, and the prognosis, a statistical analysis was made, but the results were inconclusive. The cumulative mortality rates of the patients with coronary sclerosis and anginal pain and of the subjects without cardiac symptoms, grouped according to the result of the initial anoxemia test, showed distinct differences. In the patients with coronary disease whose tests were positive, the prognosis was significantly worse with respect to longevity than in those whose tests were negative. It should be emphasized, however, that, whereas this is true for the group as a whole, it does not necessarily apply to any individual patient. The anoxemia test furnishes an index of the coronary erve only at the time of its performance.

um Alkaloids versus Hexamethonium Bromide in Hyper- —In 36 patients with arterial hypertension attempts were le to reduce the blood pressure by oral administration of ixed Veratrum alkaloids. In 27 continued treatment with hexamethonium bromide was also attempted. The blood pressure was reduced substantially without important symptoms in 10 of 36 patients with mixed Veratrum alkaloid therapy and in all of 27 patients with hexamethonium bromide injected subcutaneously. Treatment with hexamethonium was continued for from 1 to 15 months. There seemed no way of predicting without individual trials which patient would respond to Veratrum alkaloids; if, however, the patient was responsive, the blood pressure level throughout the day could usually be well controlled by spacing the doses, though mild toxic symptoms were likely to occur periodically. Moreover, Veratrum alkaloids seemed to be safe in the proper doses, and their hypotensive action was not excessive. Administration is easy, and, if tolerance to the drug does develop, it is very slight. Mixed Veratrum alkaloids seem unsuitable for treatment of acute cardiac complications of hypertension and encephalopathic attac ratrum
alkaloids and hexamethonium bromide resemble e in
that the therapeutic range of dosage is narrow. Grad
can be obtained with less difficulty using hex
bromide. Continued administration leads to drug tol
hexamethonium bromide, but not with Veratrum alk

sure falls a the standing, intermediate in the
and least in e. After ingestion of Veratru
loids postural conspicuous. After ingesthexamethonium bromide the pulse is ordinarily accelerated, but following continued treatment it may be unchanged. Bradycardia occurs with Veratrum alkaloid therapy. The main toxic manifestation of hexamethonium bromide is faintness and lassitude associated with excessive fall of blood pressure; the symptoms are maximal when the blood pressure is at its lowest level. Toxic effects of the Veratrum alkaloids occur while the blood pressure is still falling, and may disappear before the blood pressure reaches its lowest level.

Effect of Pasteurization on Coxiella Burnetii.—The effect of pasteurization on the survival of Coxiella burnetii was investigated. Pasteurization was carried out in commercial processing plants under routine conditions. In 1 of 35 instances the organism survived pasteurization by the vat-holding method; in this instance, however, pasteurization, as judged by the phosphatase test, may not have been complete. In 2 instances of 42 the organisms were detected in milk pasteurized by the high temperature and short time method. In an addendum to this report the authors state that after this paper had been prepared for publication, there came to their attention the report of Marmion and his associates on "The Effect of Pasteurization on Milk Containing Rickettsia Burneti," (*Monthly Bull. Ministry of Health and the Pub. Health Lab. Service* 10:119-128, 1951). These workers found that treatment of naturally infected milk at 154 to 156 F for 15 seconds was sufficient to render the milk noninfective for guinea pigs. On the other hand, artificially infected milk containing large numbers of rickettsiae still possessed infectivity after treatment at 158 to 159 F for 15 seconds, but was rendered noninfective after treatment at 161 F for 15 seconds.

Observations on "L. E." Phenomenon.—After re-
nt literature on the "L. E." cell phenomenon,
present their method for obtaining, preparing,
staining peripheral blood and bone *marrow*

specimens. Using this technique they examined approximately 5,000 peripheral blood and 800 bone marrow specimens of patients referred to a hematology service during one year. They demonstrated L. E. cells in five patients. They found that the L. E. cell has two component parts. The L. E. cell inclusion body was always a mature, autolyzed polymorphonuclear neutrophil. The phagocytic cell was either a mature polymorphonuclear neutrophilic, eosinophilic, or basophilic leukocyte, with the neutrophilic leukocytes overwhelmingly predominating. Bone marrow examination proved the most reliable means of demonstrating L. E. cells by their technique, even though, on routine examination, they found L. E. cells in the peripheral blood in four of the five summarized cases. The authors regard this as a simple, effective, direct method for demonstrating L. E. cells without special procedures on peripheral blood or bone marrow.

Hepatic Fibrosis in Cardiac Disease.—Moschcowitz prefers the term fibrosis to cirrhosis, and points out that there are widely differing opinions concerning the morphology and pathogenesis of hepatic lesions associated with cardiac disease. The earliest phase in the development of this condition is that characterized by what is usually referred to as "nutmeg" liver, in which there is dilatation of the central sinusoids with trabecular narrowing. Later, centrolobular necrosis ensues. Thereafter, the morphological changes depend on whether hypertension of the portal circulation is maintained long enough. This usually occurs in constrictive pericarditis, often in the terminal stages of tricuspid valve disease. That portal hypertension is maintained was shown by histological demonstration of "congestive splenomegaly." Under such circumstances, various forms of fibrosis occur: first, capillary sclerosis around the central veins; second, organization of the centrolobular necrotic areas with the development of new central veins in these fibrotic areas, either by autochthonous formation of capillaries or by direct sprouts from the terminal branches of the portal vein in the interlobular septa; and third, by sclerosis of the hepatic veins and the immediately adjacent parenchyma. The periportal fibrosis that has been described as occurring in "cardiac cirrhosis" bears no resemblance to that observed in true Laennec's cirrhosis. Cardiac fibrosis is not a replacement fibrosis but is an active and proliferative process. New capillary shunts or short circuits are developed simultaneously. There are four kinds of such shunts: first, between the terminations of the portal vein and the central vein in the interlobular septa; second, by newly formed capillaries that bud from the terminal branches of the portal veins within the portal septa to the central veins; third, by budding from the preexisting portal branches in the interlobular septa to the newly formed central veins; and fourth, by direct capillary communication between the terminations of the portal veins in the interlobular septa and the hepatic veins. These shunts are compensatory mechanisms to help equalize the pressures between the portal vein and the hepatic veins. Evidence is submitted that the morphological changes of cardiac fibrosis are the result of portal hypertension of central origin. Advanced hepatic cirrhosis may be suspected if there is constrictive pericarditis of long duration, persistent and recurring ascites, increased peripheral venous pressure, splenomegaly, and enlargement of right auricle and ventricle, and dilatation of the pulmonary artery.

Cortisone and Gold in Chronic Rheumatoid Arthritis.—A total of 92 patients with active chronic rheumatoid arthritis were divided into four series: first, eight patients who had been receiving gold with only moderate benefit were given cortisone in addition; second, 13 patients were given gold and cortisone concurrently; third, 42 patients were given gold alone; and fourth, 29 patients were given cortisone alone. For comparison, 273 patients who received neither gold nor cortisone were restudied. The dosage levels were as follows: Cortisone was given in doses of 100 mg. intramuscularly every eight hours for 24 hours, then every 12 hours for 24 hours, and then 100 mg. daily for 21 days. Then cortisone therapy was discontinued until a relapse occurred. It was then reinstituted at the previous level and, after 14 days, 75 to 100 mg. were given every other day parenterally, or 50 to 75 mg. per day orally. Administration of cortisone was then again discontinued. Gold was given in initial doses of 10 mg. either intramuscularly or intravenously, and then at weekly intervals in 50 mg. doses until a total of 1 gm. had been given. Administration of gold was then continued at 10, 14, 21, and 30 day intervals. The authors gained the impression that gold given to patients with active chronic rheumatoid arthritis with moderate benefit apparently had no additional effect when cortisone was added. Despite an excellent therapeutic response, no complete remissions were observed in this group of eight patients, and they returned to their precortisone state shortly after administration of the hormone was discontinued. Gold given concurrently with cortisone seemed to arrest rheumatoid arthritis in approximately the same percentage of patients as gold given alone, but it appeared superior to cortisone employed alone, and to therapy without gold or cortisone. Gold and cortisone administered concurrently gave an immediate increase in functional capacity, and in some patients it produced a complete remission. These effects continued in a number of patients when cortisone was discontinued. In addition, the concurrent administration of gold and cortisone has several therapeutic advantages: first, patients who have previously been intolerant to gold can be given gold with cortisone with less danger of a reaction (to gold). Second, with cortisone rehabilitative measures can be carried out before the gold levels are sufficiently high to be effective. Third, administration of cortisone may be discontinued in the patients who respond to gold.

Soft Tissue Calcification.—The term calcinosis circumscripta and calcinosis universalis imply the deposition of calcium salts in skin and subcutaneous tissue. Much of the confusion and mystery surrounding the use of the terms calcinosis circumscripta and calcinosis universalis stems from the practice of regarding calcification as a primary process, whereas careful study will always reveal a primary disease responsible for the calcification. This report is concerned with the 54 instances of calcinosis of the circumscript or universal varieties reported in the literature since 1938 and 12 cases of several types of collagen disease studied by Wheeler and associates at the University of Michigan Hospital. Detailed reports are given of two of the latter 12 patients and brief reports of the other 10. A table that lists the primary diagnoses of all the 66 patients with calcinosis of the circumscript or universal varieties shows that most patients had scleroderma, Raynaud's syndrome, or dermatomyositis. Thirty-four of the patients are in the scleroderma group and 32 in the dermatomyositis group. In general, serum calcium, phosphorus, and alkaline phosphatase determinations are reported as normal in collagen diseases associated with calcification, but it is suggested that possibly calcium is being removed from the blood and stored in injured tissue. Calcification may be secondary to a disturbance of factors regulating blood serum calcium and/or phosphorus levels. It may also occur in the so-called collagen diseases as a result of tissue injury. The following diseases should be considered when calcinosis is found: scleroderma, dermatomyositis, Raynaud's syndrome, rheumatoid arthritis, acrodermatitis chronica atrophicans, hyperparathyroidism, vitamin D intoxication, metastatic bone disease, multiple myeloma, Paget's disease of bone, renal failure, and pseudohypoparathyroidism. A table lists the results of laboratory tests and roentgenograms of the skeletal system to be expected in these conditions.

Electrolyte Abnormalities in Pyloric Obstruction.—Prolonged untreated illness and protracted use of potassium-free intravenous fluids may result in electrolyte imbalances. The loss of sodium and chloride accompanying vomiting is well known, and recent studies have shown that a considerable amount of potassium may also be lost as a result of vomiting or prolonged gastric suction. Patients with gastric carcinoma or vagotomy may have alkalosis, hypochloremia, and hypopotassemia, because high concentrations of chloride and potassium ions may be present in the gastric contents in spite of the absence of titratable hydrochloric acid. Analysis of the gastric contents in patients with pyloric obstruction shows that their daily potassium loss may qual from 6 to 8 gm. of potassium chloride. The loss of chloride ceeds that of sodium when the obstruction is due to peptic lcer, because free hydrochloric acid is present in the gastric juice; this leads to hypochloremia and alkalosis. Gastric resection, on the contrary, usually results in a loss of sodium exceeding that of chloride, leading to acidosis. Hypochloremia and alkalosis resistant to isotonic sodium chloride solution may be corrected by intravenous potassium chloride therapy. The addition of 3 gm. of potassium chloride to a liter of isotonic sodium chloride solution, amino acids, or 5% dextrose solution provides potassium and chloride ions in excess of sodium, resulting in an increase of intracellular potassium and extracellular chloride. Such solutions should be administered at the rate of from 120 to 180 drops a minute; faster administration may lead to a high serum potassium level, which is toxic to the heart and may cause heart block and cardiac arrest. Potassium must be given cautiously to patients with renal insufficiency or dehydration. Parenteral potassium therapy is not needed after the patient is able to eat, because most foods are good sources of potassium. This treatment resulted in a striking improvement in the mental attitude and muscular strength of all patients; 14 were in critical condition when it was begun, but all responded to therapy and there were no deaths.

Response of Bishydroxycoumarin-Induced Hypoprothrombinemia to Vitamin K_1.—Vitamin K_1 in the form of an emulsion may safely be given intravenously. It has proved effective in reversing hypoprothrombinemia due to bishydroxycoumarin (dicumarol®) and other prothrombin-depressing drugs, returning the prothrombin time to normal or nearly normal levels in approximately six hours irrespective of the degree of hypoprothrombinemia and the amount of recently administered bishydroxycoumarin. The response to a dose of 50 mg. was as prompt and effective as it was to larger doses; when a 50 mg. dose was given, resistance to subsequent doses of bishydroxycoumarin did not develop. The fact that vitamin K_1 controls bleeding by correcting the coagulation defect more rapidly than any other agent makes the use of whole blood and plasma unnecessary except when blood volume replacement is required. Vitamin K_1 is also valuable in reversing hypoprothrombinemia immediately before operation, and in reducing excessive hypoprothrombinemia not accompanied by bleeding to a therapeutic level so that anticoagulant therapy may continue without interruption. For the latter purpose doses of from 0.5 to 2.5 mg. of vitamin K_1 given intravenously will reverse the prothrombin time rapidly, returning it in most instances to a safe but still therapeutic level in from three to six hours when average doses of bishydroxycoumarin have resulted in excessively high levels.

Hydrazine Derivatives of Isonicotinic Acid in Tuberculosis.—The authors report results of treatment with the hydrazide of isonicotinic acid ("rimifon") and its isopropyl derivative ("marsilid") in 92 patients with moderately or far-advanced pulmonary tuberculosis. All patients had positive sputum and active disease before institution of therapy; 45 were toxic and febrile. Patients, divided into groups, were treated with 2, 4, and 10 mg. per kilogram of "marsilid" and 4 mg. of "rimifon" for from 4 to 15 weeks. Fever and toxicity disappeared within two to three weeks in all cases. Improvement in appetite and in sense of well-being was associated with weight gains, which were as great as 64 lb. (29 kg.) and averaged 18 lb. (8.2 kg.) in nine weeks of treatment. The sputum became negative in 25% of patients and in another 28% sputum that had been consistently positive became "occasionally positive." Cough and expectoration disappeared completely or almost so in from two to three weeks. Cavity closure occurred in 2 cases, marked reduction in cavity size was noted in 33 cases, and clearing of exudate occurred 17 times. In four cases the exudate became more extensive, and in one case a new cavity seemed to form where exudate had been present before treatment. Cure or great improvement was observed in patients with tuberculous laryngitis, otitis, or glossitis. Toxic effects of marsilid and rimifon therapy included hyperreflexia, leg-twitching, constipation, vertigo, and reflex disturbance of micturition. No fatality resulted from use of these drugs, and every patient was benefited.

Streptomycin in Skeletal Tuberculosis.—Of 90 patients with skeletal tuberculosis observed for 15 months, 50 were given at least one course of streptomycin with daily intramuscular doses of 20 mg. per kilogram of body weight for 91 days, while 40 were not treated with streptomycin. The small number of patients in the streptomycin and control groups limits the conclusions that may be drawn from the authors' observations, which are as follows: 1. On the basis of x-ray evidence alone, the condition of the patients in the streptomycin-treated and in the control groups was essentially the same; more than four-fifths of the patients in each group showed improvement roentgenographically at the end of 15 months. 2. On the basis of the patients' condition as judged by x-ray and clinical data combined, there was more improvement in the streptomycin-treated patients. At 15 months only 28 of the 40 patients in the control group showed improvement, whereas improvement was noted in 38 of the 50 streptomycin-treated patients as early as three months, and in 41 patients of this group at 15 months. 3. Streptomycin appears to produce a generalized effect on the well-being of the patient with skeletal tuberculosis and on the secondary manifestations of the tuberculous process, as illustrated by cessation of sinus drainage, reduction in the sedimentation rate, return towards a normal hemoglobin level, and evidence of greater improvement in functional ability. The data appear to substantiate the hypothesis that because of the relative avascularity of bone lesions and because a tuberculous focus is usually isolated by fibrous tissue walls, little streptomycin reaches the skeletal lesion. Hence the roentgenographic evidence of progress is quite similar for the streptomycin and control groups. However, streptomycin may ameliorate the toxic effects of the tubercle bacillus, and, in contiguous areas where the vascular supply is better, may decrease the spread of the disease process and bring about improvement in the general condition. Clinically patients treated with streptomycin were in a better condition than the control patients.

Surgical Drainage Combined with Streptomycin in Tuberculous Bone Disease.—Treatment with streptomycin in doses of 1 gm. per day intramuscularly in conjunction with the surgical incision of abscesses, débridement of lesions, and their conversion to freely draining sinuses by the use of gauze packing was practiced between October, 1946, and April, 1950, in 52 patients between the ages of 1 and 72 years who had 63 closed tuberculous bone lesions. Excellent results were obtained in 37 of the 52 patients, with cessation of bone and joint destruction, closure of all sinuses, absence of pain, retention of 75% or more of active peripheral joint motion or solid surgical fusion when performed, no recurrence of drainage, and improvement in general health. Thirteen patients obtained good results, with cessation of bone and joint destruction, closure of all sinuses, relief of pain, retention of 25 to 75% of active peripheral joint motion, recurrence of slight drainage (additional streptomycin being required for closure), and improvement in general condition. Two patients died, one 18 months after operation, of tuberculosis of the kidney and lungs and amyloid disease, although the bone lesions were healed. The other died of amyloid disease and destruction of the kidneys 37 months after operation. Although the series is small and the average follow-up period of three and a half years is short, the following preliminary conclusions may be drawn: Following adequate surgical drainage and treatment with streptomycin, destruction from bone and joint tuberculosis ceased, and roentgenograms showed evidence of recalcification and apparent regeneration of bone. There was no tendency toward reactivation of the lesion, clinically or symptomatically. In the surgically produced sinuses, subsidence of drainage and closure in from 3 to 16 weeks occurred. Although the surgically treated lesions will heal clinically, new lesions in other parts of the body may develop and progress, despite administration of streptomycin. Bone tends to regenerate in children, with reestablishment of an apparently normal epiphyseal plate and no disturbance in the rate of growth. A good functional range of motion was the usual end result, even when there was roentgenographic evidence of extensive destruction of the joint. The factor of secondary infection was apparently of no consequence in the arrest and healing of these lesions.

- *Potassium Deficiency States and Their Clinical Management. H. H. Cook Jr.—p. 27.
- Effects of Hepatic Factors on Peripheral Vascular System. C. McMillan. —p. 38.

Potassium Deficiency.—Reviewing the present status of knowledge on potassium deficiency, Cook stresses that it is a common disorder and should be suspected any time oral feeding is diminished sharply or discontinued with continued urinary excretion or there is persistent loss of gastrointestinal secretions in any form, and in diabetic acidosis and coma. Potassium deficiency also occurs in digitalis intoxication, with adrenocortical substitution therapy (including administration of corticotropin), in familial periodic paralysis, and in bulbar poliomyelitis, and is of particular importance in the latter where there is usually a marked decrease in respiratory reserve. The symptoms associated with hypopotassemia are nonspecific but usually include weakness, drowsiness, langour, hypotonia of the skeletal muscles, dyspnea with gasping respiration, cyanosis, nausea, vomiting and occasionally mild sensory disturbances in the form of mild paresthesias. The diagnosis depends not so much on the symptomatology as on recognition of situations in which potassium deficiency is likely to occur. The electrocardiogram is the most practical adjunct to the clinical impression. Typical electrocardiographic changes are prolongation of the Q-T interval. The T wave is decreased in amplitude and ultimately inverted. The S-T segment sags, and the S-T takeoff is depressed. These signs are exactly opposite to those characteristic of potassium intoxication. In the treatment of potassium deficiency the oral route is preferred, and potassium chloride is probably the best drug. There is no danger from oral potassium therapy in patients with good renal function, but adequate laboratory facilities should be available when potassium is administered intravenously.

Cortisone in Congenital Adrenal Hyperplasia.—Eleven patients with congenital adrenal hyperplasia were treated continuously with cortisone for from five to 17 months. Six were female pseudohermaphrodites between the ages of 8½ and 18½ years, three were female pseudohermaphrodites, between 11 and 19 weeks of age when treatment was started, with defects of electrolyte regulation and two were boys with macrogenitosomia praecox, aged 4½ and 7 years. As a result of their experience with these patients, the authors make the following tentative suggestions: To obtain rapid suppression of the abnormal androgenic activity of the patient's adrenals, initial treatment with relatively large doses of intramuscular cortisone may be given. For patients eight years of age or over, 50 mg. of cortisone intramuscularly per day are adequate; in infants, 25 mg. per day. It seems preferable to begin treatment with cortisone intramuscularly rather than orally, because the results are more predictable. The maximum suppression of urinary ketosteroids should be attained within 5 to 10 days, after which the maintenance dose should be determined. For patients over 8 years of age the maintenance dose of cortisone given intramuscularly is usually 25 mg. per day. Doses of 75 mg. of cortisone every third day or 100 mg. every fourth day are just as effective. When cortisone is given orally doses of 50 or 75 mg. per day are required. These amounts should be given in equally divided doses, two, three, or four times a day. For young infants the maintenance dose of cortisone is smaller. In the authors' patients, intramuscular injections of 5 mg. daily and of 25 mg. every fourth day and oral doses of 5 mg. and 12.5 mg. per day seemed to maintain suppression, but larger amounts may be required in some cases. For children between the ages of 1 and 8 years, the maintenance dose is probably somewhere between these amounts and 25 mg. per day, when the drug is given intramuscularly. It should be determined individually for each patient. The effects of intramuscular medication seem to be more predictable, probably because of the more uniform rate of absorption. In young infants who have the sodium-losing type of congenital adrenal hyperplasia, it is important that treatment include a high sodium intake and/or desoxycorticosterone in addition to cortisone. In the one patient who was given compound F (17-hydroxycorticosterone) in doses of 25 mg. per day, it seemed to have approximately the same effect as cortisone on the suppression of adrenal activity. In an infant with the salt-losing type of adrenal hyperplasia, compound B (corticosterone) seemed to have somewhat less suppressive action than cortisone, but a definite sodium-retaining effect was exerted by doses of 12.5 mg. per day. The ultimate effects on the adrenal of the amounts of cortisone administered are not known. Although cortisone seemed to suppress the response of the adrenal to 24 hour tests with corticotropin (ACTH), the activity of the adrenals as measured by the 17-ketosteroid excretion returned promptly when cortisone was discontinued after 227 days of continuous therapy.

Effects of Cortisone on Sexual and Somatic Development.—The effects of cortisone on sexual and somatic development were studied in the 11 patients with congenital adrenal hyperplasia who were treated continuously with this drug for 5 to 17 months as reported in the preceding paper. In all six girls between the ages of 8½ and 18½ years the breasts promptly developed and the vaginal smears showed estrinization. Three of these patients have menstruated regularly. There has been an unquestionable decrease of hirsutism in all patients, and in two the decrease was quite pronounced. To obtain the most satisfactory results, it is essential to give the minimum amount of cortisone necessary to maintain the excretion of 17-ketosteroids below 8 mg. per day in the older patients, as recurrence of androgenic manifestations was observed when larger amounts of ketosteroids were excreted. In one infant, 25 mg. of intramuscular cortisone daily inhibited growth and osseous development, while 5 mg. suppressed excessive androgen secretion without inhibiting normal growth. During childhood it is advisable to follow both the urinary 17-ketosteroids and the rates of growth and osseous development as guides to treatment. The minimal effective dose of cortisone and the level at which the urinary 17-ketosteroids should be maintained must be determined individually in each case. In one of the two boys with macrogenitosomia praecox, cortisone led to adolescent development and growth of the patient's testes, suggesting that normal maturation was occurring. The rapid female sexual development in three pseudohermaphrodites between 8½ and 10½ years old and the testicular development in a boy aged 7 may be due to the fact that these patients had attained a somatic and osseous development of from 13 to 15 years, owing to the accelerating effects of excessive androgen. Apparently the pituitary-gonadal mechanism had matured enough to be capable of functioning promptly as soon as the inhibiting effects of adrenal hormones were suppressed.

Effect of Corticotropin, Cortisone, and Operative Stress on Blood Cholesterol.—Kyle and associates followed the blood cholesterol levels of patients during administration of corticotropin and cortisone and following the stress of surgical intervention, and compared the observed changes with variations seen in normal persons. They found that the determination of plasma cholesterol and cholesterol esters by chromatographic separation is reproducible within 2% on repeated determinations on the same sample. The variation in plasma cholesterol content on the same patient within two to eight hours is likewise within 2%, and for periods of from two to eight days the variation is approximately 5%. The administration of corticotropin in nine patients caused an average reduction of total cholesterol of 24%, and the greater decrease in cholesterol was well correlated with greater physiological stimulation by corticotropin. In two patients who obtained little stimulation from the corticotropin there was no significant depression of cholesterol. Intravenous administration of corticotropin to one patient for 20 days and to another for 14 days produced a marked decrease in plasma cholesterol. The effect of the administration of cortisone to nine patients was less consistent than that of corticotropin. The average change was a decrease of 7%, but a more marked decrease was observed in two patients who were given larger doses of cortisone. Compound F was given to one patient for 20 days, producing only a slight decrease in plasma cholesterol, although a marked decrease in the eosinophil count occurred. In 9 of 10 cases there was a decrease in plasma cholesterol following surgery, the decrease occurring later than the reduction in eosinophil count. It is suggested that the decrease in blood cholesterol that accompanies administration of corticotropin is caused by direct action of the adrenal hormone, either by inducing temporary impairment of hepatic function, or, more probably, by suppressing cholesterol synthesis.

Clinical Aspects of Cold Injury.—Cold injury is trauma produced by exposure to cold, and includes such entities as chilblains, immersion foot, trench foot, and frostbite. Of 593 patients at the average age of 22, who with the troops in Korea had been exposed to temperatures of −20 to −30 F and were evacuated to the United States for frostbite treatment, 474 (80%) had either superficial or deep gangrene. Eighty per cent of the patients had involvement of the feet only, 16.8% had involvement of both feet and hands, and 3.2% had involvement of the hands only. Clinical experience with these patients showed that it is almost impossible to determine accurately the amount of tissue damage or whether amputation will be required without prolonged observation, up to three months in some cases. Conservative therapy is indicated to insure maximum preservation of function. The necrotic eschar on digits should be bivalved early to prevent contraction and further tissue damage. Ointments, particularly white petrolatum U. S. P. (vaseline®) gauze, are contraindicated as they result in ulceration and infection. Hexamethonium was the most effective vasodilator, as shown by high and prolonged elevation of skin temperature. This drug is just as effective as lumbar blocks and much simpler. Priscoline® (2-benzyl-4,5-imidazoline) hydrochloride administered orally was the next most effective agent. The use of vasodilators made no clinically evident difference in the rate of healing, but may have lessened the incidence of "post frostbite syndrome," such as cold feet with dependent rubor and/or cyanosis and hyperhidrosis. Administration of corticotropin (ACTH) and cortisone resulted in mild euphoria, lessening of pain, decrease in purulent drainage and odor, and apparently earlier demarcation of the necrotic area. Neither drug lessened the amount of tissue loss nor resulted in more rapid healing of the lesions. Soaks in warm, sterile, isotonic sodium chloride solution softened the eschar and in some cases apparently promoted more rapid healing.

Some Practical Aspects of Cancer Prevention. E. L. Wynder.—p. 538.

The Vaginal Smear as a Screening Test.—A single vaginal smear was obtained from each woman who attended the state-aided cancer clinics of Massachusetts between Jan. 1, 1945, and June 30, 1947. Three years after the original smear a follow-up history and, whenever possible, a pelvic examination and a repeat smear were secured. The total number of records was 3,581. Of the 210 women in whom cancer was diagnosed at the time of the original smear, 62.4% showed a positive test, 23.8% a questionable test, and 13.8% a negative test. Thus, the tests did not indicate that cancer was present in nearly one-seventh of those who had cancer of the uterus. Of 1,888 persons who had no apparent cancer of the uterus at the time of the smear or three years later, 1.9% originally showed a positive smear, 5.9% a questionable smear, and 93.1% a negative one. It is true that a few unsuspected cases of cancer have been discovered through the use of the vaginal smear, but the cost per discovered case was approximately $1,700. The large error found among the group most likely to have cancer (those who bleed) impairs the diagnostic value of this test for screening purposes. It does not seem feasible for a state health department to offer this test on an extensive scale for women without gynecologic symptoms, as the cost would be prohibitive and relatively few cancers would be found. The authors reiterate that they are not concerned with the value of the vaginal smear as a means of diagnosis per se, but rather with its use as a method of screening large populations. Its usefulness as a screening procedure is obviously less than in the study of an individual case.

Visualization of Mediastinum.—Study of the posterior mediastinum is difficult, particularly in children, in whom gas insufflation following transtracheal puncture has been considered inadvisable. The authors found the intraspinal, extradural approach, that is, injection of a gas contrast medium into the peridural space, ideal for use in children. This technique permits simultaneous, sharp visualization of both the anterior and posterior mediastinum. It is easy, safe, and well tolerated by children. Used with tomography (in anteroposterior, lateral, and axial transversal projections) this method gives interesting tridimensional pictures.

Mass BCG Vaccination in Malta.—Between March and June, 1950, 54,328 persons in Malta were tuberculin-tested, and 38,681 were vaccinated with BCG. Of the latter 36,320 were between the ages of 1 and 18 years and 2,361 were over 18. This campaign was held because destruction of habitable dwellings during World War II and the ensuing housing shortage had resulted in severe overcrowding, favoring spread of tuberculosis. The tuberculin tests indicated that between the ages of 16 and 20 more boys than girls were infected with tubercle bacilli. This is in accord with the finding that in this age group more males developed pulmonary tuberculosis, in whom, however, it was less likely to be fatal than in females. The incidence of tuberculosis infection and of pulmonary tuberculosis were lower in the rural areas, while in the semirural, suburban, and urban areas they were approximately the same. BCG vaccination was carried out by means of Wallgren's intradermal injection technique, using 0.1 ml. of a vaccine containing 0.025 mg. of BCG or about 1 million "BCG bacilli" per 0.1 ml. An accelerated reaction at the site of inoculation was observed in 11 persons. Between the 30th and 53d days after vaccination 23 patients had discharging ulcers, which tended to heal rapidly. Of 54 persons with lymph node enlargement in the axilla following BCG vaccination, 2 had a secondarily infected BCG ulcer, and 2 complained of discomfort on movement, while in 21 children between the ages of 1 and 6 years the condition progressed to suppuration. Elevation of temperature following the vaccination was rare, one person had erythema nodosum, and 17 had phlyctenular conjunctivitis. To check the efficacy of both the vaccine and the technique of its administration, postvaccination tuberculin tests were given to 2,421 unselected persons according to the epinephrine-Pirquet technique. Positive reactions occurred in 98.95% of these persons. Up to 12 to 15 months after the campaign no cases of tuberculosis had been reported among persons vaccinated with BCG.

Determination of Bacterial Sensitivity to Antibiotics. J. C. Gould and J. H. Bowie.—p. 178.
Staph. Aureus Air Infection in Maternity Hospital. A. T. Wallace and J. P. Duguid.—p. 200.

BCG Vaccination as Public Health Measure.—Experience with BCG vaccination in about 17,000,000 persons in the Scandinavian countries, in the war-devastated countries in Europe, and in undeveloped countries outside Europe suggests that adequately performed BCG vaccination produces specific immunity strong enough to provide protection to a great extent against severe tuberculosis, miliary tuberculosis, and tuberculosis meningitis, and to a certain extent against pleurisy and postprimary pulmonary tuberculosis. The morbidity and mortality rates of tuberculosis have been reported to be lower in groups of adequately vaccinated persons than in nonvaccinated groups of tuberculin-negative persons. Most observers believe that BCG vaccination should be accepted as a public health measure against tuberculosis. BCG vaccination in itself will not abolish tuberculosis in a community. Other measures are more important, such as those aimed at preventing tuberculous infection, at increasing the natural resistance of the population by a high standard of living, at early detection of tuberculous disease, and at giving every person in need of it adequate treatment. The object of BCG vaccination is to produce artificial specific immunity in persons who still are uninfected, and the earlier artificial immunity is established the better. In a country with high incidence of tuberculosis vaccination of children as young as possible is advisable as a public health measure. If most babies are born in maternity hospitals, the BCG vaccination is most conveniently performed on newborn infants, without any preliminary tuberculin testing. By tuberculin control and revaccination if necessary, the virulent infection, when and if it occurs, is generally prevented from producing clinical primary tuberculosis and early postprimary disease. In persons of all age groups exposed to sources of infection, such as children in homes with tuberculous patients and hospital personnel, BCG vaccination should as a public health measure be performed in those still tuberculin-negative.

Betatron in Cancer Therapy.—Observations on 58 patients with advanced cancer treated by means of a 22 *mev* betatron are reviewed. A 22 mev betatron has limited usefulness in treatment of deep-seated lesions. It does not appear to have specific biological advantage over conventional x-rays, but does have certain physical attributes that can be used to advantage. Constitutional effects are minimal. Lack of variation of depth dose with field size makes for simplicity. The low skin dose compared with a very high depth dose is of great value. The immediate results, in advanced cases of cancer of the cervix and bladder, were promising, but the doses given apparently caused disappearance of detectable signs of the tumor rather than eradication. It has been impossible to achieve a dose lethal for the tumor in most cases. The limiting factor in treatment of cancer of the cervix is the effect on the bowel and bladder, but even irradiation to the pelvis is possible. A dose of 6,000 r to the whole pelvis delivered in three weeks was considered the maximum possible. Considerable palliation was achieved in advanced tumors of the lung and brain. The response of cancer of the rectum was disappointing.

Thymectomy in Myasthenia Gravis.—A benign hyperplastic thymus gland was removed from 100 consecutive patients with myasthenia gravis. Only one of the seven patients who died postoperatively died of myasthenia gravis. Of the survivors, 41 patients have no symptoms and require no treatment; 26 have slight and inconstant symptoms and are able to work with no limitations due to myasthenia gravis, with irregular and much less treatment than before the operation; 20 patients have fewer or less severe signs and symptoms, and respond to a significantly smaller dose of neostigmine as well or better than before the operation; and 6 patients are unchanged or worse. The benefit was greatest in the patients who had had myasthenia for the shortest time before operation. The age of onset did not seem to be significant. Comparison with three series of patients treated by medical means alone reveals that among these the proportion of cured or greatly improved is smaller and the proportion of deaths due to myasthenia gravis much higher than in the group presented here.

Prevention of Acute Dinitro-Ortho-Cresol Poisoning.—In Great Britain eight fatal cases of poisoning have occurred since 1945 in men engaged in the manufacture of dinitro-ortho-cresol, and in spray operators using dinitro-ortho-cresol for control of weeds in cereal crops. No cases of poisoning have been recorded among men who use the substance as a late winter wash on fruit trees. Experiments on volunteers showed that, when the dinitro-ortho-cresol level in the blood was about 20 μg per gram a further dose of about 1 mg. per kilogram of body weight led to a sharp increase in the concentration of this compound in the blood, and when this was more than 40 μg per gram all the volunteers had headache, lassitude, and general malaise. When the level of this substance in the blood was about 20 μg, all the volunteers had an exaggerated feeling of well-being. Single estimations were made on blood collected from 23 workers engaged in manufacture of dinitro-ortho-cresol, 39 men using dinitro-ortho-cresol as a late winter wash on fruit trees, and 133 spray operators applying dinitro-ortho-cresol to cereal crops. The dinitro-ortho-cresol levels in four cases of acute poisoning show the correlation between the blood level and the symptoms and signs of poisoning. A man should be removed from further contact with this compound for a minimum of six weeks if the dinitro-ortho-cresol level eight hours after the last exposure is 20 μg per gram or higher. Since the main route of absorption is by inhalation, respirators should be worn, especially by spray operators. The authors consider that estimation of dinitro-ortho-cresol levels in the blood might prove a valuable measure in the prevention of acute poisoning, but that determination of dinitro-ortho-cresol in the urine is unlikely to prove a reliable test.

Flexible Plastic Tube Adapter for High-Pressure Injections. D. G. Renton.—p. 408.

Surgical Relief of Mitral Stenosis.—Commissurotomy according to the techniques of Bailey and Brock was performed by a posterolateral approach through the bed of the left fifth rib in 23 selected patients with mitral stenosis. The first patient was treated in March, 1951. Separation of the valve cusps at the commissures with the finger was attempted. If this was not possible, the finger was withdrawn and a small commissurotomy knife fashioned to fit the curve of the finger was inserted. With the knife it was usually easy to slit the valve and then carry out digital dilatation to the muscular wall of the heart. One patient with severe stenosis died during the induction of anesthesia, although adequately prepared for surgical intervention, and a second patient with auricular fibrillation of several years' standing died of embolism in the cerebral and iliac vessels on the third postoperative day. Patients with a very large heart, with established right-sided failure, with free mitral regurgitation, with significant aortic valve disease, or with active rheumatic carditis should not be operated on. In patients between 30 and 45 years of age who are not in a state of congestive failure, who have not had severe congestion, but who have had recurrent "bronchitis," pulmonary edema or hemoptysis and are seriously incapacitated, the operative mortality should be negligible and the results should be good. Two of the 21 living patients were not yet well enough for their improvement to be assessed, but 14 showed great improvement, 2 were only slightly improved, and 3, in whom for technical reasons dilatation was unsuccessful, were unimproved. The only serious postoperative complication was auricular fibrillation, which was controlled with digitalis and quinidine. The severity of the lesion was demonstrated preoperatively by cardiac catheterization in four of the first six patients operated on; the authors now carry out this procedure as a routine measure before considering surgical treatment. The authors' results and those of other workers suggest that sooner or later every patient with mitral stenosis should be treated surgically.

Excretion of Tubercle Bacilli by Patients with Inactive Pulmonary Lesions.—Frequent control tests were carried out over long periods on the sputum and gastric contents of 445 patients who had had an open form of pulmonary tuberculosis but had been clinically cured. It was found that 18% continued to eliminate tubercle bacilli intermittently. In about 15% of the patients the last 10 specimens examined for tubercle bacilli were negative, but since prolonged intermission in excretion of bacilli of from four to six months had occurred before, it is not certain whether the lesions in these patients are definitely closed.

*Anti-Edematous Therapy Combined with Palliative Chemotherapy of Epithelial Cancers. A. Morel and A. Josserand.—p. 490.
Pathology and Treatment of Abortions of Endocrine Origin. M.-F. Jayle. —p. 492.

Anti-Edema Therapy in Epithelial Cancers.—The frequent early, severe relapses following incomplete cytocidal therapy in cancer may result from perifocal swellings caused by an allergic reaction to the products of partial tumor lysis. Neoplastic cells proliferate in the edematous fluid and the exudates, carried by greatly dilated lymphatic vessels, cause distant, so-called inflammatory, adenopathies; these in turn are colonized by the cancer cells. Excellent palliative results with apparent stabilization of the tumors have been obtained by treatment in three stages: a cytocidal attack; brief, intense therapy to reduce edema; and a fairly long period of antihistaminic therapy designed to prevent reinfiltration of the perifocal area. Treatment begins with the intravenous administration of sodium oxyferriscorbone in 2 or 3 cc. of 30% hypertonic glucose solution morning and evening for five days to prepare the perifocal area for the cytocidal attack. No treatment is given on the sixth day, but on the seventh colchicine is given intravenously followed by from four to six additional injections of sodium oxyferriscorbone. Twenty days of antihistaminic therapy follow, including intradermal injection of an antihistamine solution every other day, to prevent the reappearance of edema. The complete series is then repeated as often as necessary. The treatment is generally well tolerated and may be individualized by such means as altering the dose or using other cytocidal preparations alternately with colchicine. The pain of epithelial cancer, which is usually caused by pressure of the fine nerve fibers owing to perineoplastic cellulitis, diminishes or disappears entirely after reduction of edema, and the effect of the cancerocidal substances is prolonged and accentuated by the decongestive treatment.

Q Fever in Umbria Region.—The occurrence of Q fever is reported in 51 persons from the Umbria region. The incubation periods ranged from 14 days to 26 days. The symptoms were elevation of temperature, severe headaches, profuse sweating, asthenia, and pulmonary involvement. Laboratory tests revealed an increased erythrocyte sedimentation rate during the acute stage of the disease, slight but frequent albuminuria, and in seven patients decreased reaction to tuberculin. The blood picture and the differential blood count remained unchanged. The liver was enlarged in four patients only, of whom two were alcoholics and one both alcoholic and diabetic. Since the urine urobilin level was normal, there was no bilirubin in the blood, and the Takata-Ara test was normal, the author concludes that usually Rickettsia burneti cause slight liver damage. Repeated tests demonstrated that the complement fixation was always positive and that the complement-fixing antibodies had not been influenced by antibiotic treatment and were still in circulation several months later. All these patients, except one, had a bronchopneumonic process, but in none was Q fever associated with another disease. According to the author, Q fever occurs both with and without pulmonary involvement. Diagnosis based on clinical findings is inadequate and laboratory tests for Rickettsia burneti are the decisive factor in differential diagnosis from primary atypical pneumonia and other febrile processes. Treatment of Q fever is not difficult, since the disease may regress spontaneously. Fifteen patients were treated with aureomycin, 13 with terramycin, 7 with chloramphenicol (chloromycetin®), and 1 with paraaminobenzoic acid. Aureomycin and terramycin were equally effective, while chloramphenicol failed in two patients. In all the other patients the disease disappeared spontaneously, suggesting that the effects of antibiotics on Q fever should not be overemphasized.

*Treatment of Celiac Disease with Corticotropin and Cortisone. J. Ugland, L. Wennevold and L. Salomonsen.—p. 420.

Etiology of Retrolental Fibroplasia.—A single case of retrolental fibroplasia was discovered among 570 prematurely born infants who weighed less than 2,000 gm. at birth. A search for etiological factors revealed that the recent introduction of a new type of incubator and the use of high concentrations of oxygen probably played a part in development of retrolental fibroplasia. They suggest two possible causes: (1) the unphysiological administration of oxygen may cause the eye lesions or (2) although the prematurely born infant may become adapted to the oversupply of oxygen, damage occurs when the baby is removed from the high oxygen atmosphere. The authors feel that oxygen must be used cautiously in prematurely born infants.

Corticotropin and Cortisone in Celiac Disease.—The four children with celiac disease whose cases are reported in this paper were boys between 15 months and 5½ years of age. They had had symptoms of celiac disease for from six months to three years. The response to dietetic treatment had been unsatisfactory. Treatment with corticotropin and cortisone was continued for from four to seven weeks, during which a modified dietetic treatment was continued. Corticotropin was given for two days in large doses, then for several weeks in an adjusted maintenance dose and finally in slowly decreasing doses. Patients who were treated with cortisone were given some corticotropin at the end of the course of cortisone. Treatment with corticotropin or cortisone effected improvement in the general condition, mood, appetite, appearance and fat content of stools, sideropenia, anemia, hypoproteinemia, and the blood sugar tolerance tests, but no effect was noted on osteoporosis, on the retarded development of the epiphyseal nucleus, or on the roentgenologically demonstrable changes in the small intestine.

Cortisone in Cirrhosis of Liver in Alcoholics. R. Cachera and F. Darnis. —p. 1085.
*Biochemical Diagnosis of Renal Lithiasis. J. Cottet.—p. 1096.

Biochemical Diagnosis of Renal Lithiasis.—Since dietetic and medicinal treatment of renal lithiasis varies according to the chemical nature of the lithiasis, biochemical diagnosis of the lithiasis was attempted by the author on the basis of a test in which crystalluria is induced. The crystalline sediment and the pH were studied systematically in the urine specimens collected in the course of one day while the specific gravity of these specimens varied physiologically. For the induced crystalluria test to be of any value, the specific gravity must exceed 1.015 in at least two or three specimens of the urine. The test was performed on 24 persons who had no signs of renal lithiasis, on 18 patients with renal colic but without evidence of calculi, and on 56 patients who had urinary calculi. Results of the tests suggested that it may be possible to infer the chemical nature of the lithiasis from the constitution of the urinary crystalline sediment. This concept was confirmed by a comparative study of the results of the induced crystalluria tests, which were done in 28 patients with one or several urinary calculi, the chemical constitution of which was known. The presence of a urate sediment indicates the formation of calculi of uric acid or oxalic acid. The presence of an oxalate sediment does not provide precise indications but is suggestive of the formation of calcium oxalate or phosphate calculi. The presence of uric acid in a mixed sediment rules out phosphate lithiasis, and the presence of phosphates in a mixed sediment rules out uric acid lithiasis.

*Spontaneous Fractures After Roentgen Irradiation. W. Greve.—p. 617.

Spontaneous Fractures After Roentgen Irradiation.—Most reports of spontaneous fractures following roentgen irradiation concerned the neck of the femur. This paper reports one case of bilateral fracture of the neck of the femur in a man, aged 79, in whom 5,500 r had been applied to a tumor of the penis and prophylactic doses of 1,800 r to each inguinal field. The fractures of the neck of the femur were accompanied by bone atrophy, but there were no signs of bone metastases. Whereas the bone tolerance dose is usually estimated at between 3,800 and 4,300 r, in this patient it was estimated that the neck of the femur had received a focal dose of only about 1,500 r. In the three other cases reported in this paper, rib fractures followed intensive postoperative irradiation after mastectomy for cancer. There was no callus formation in these cases; on the contrary, the irregular fracture cleft became enlarged, in some cases up to 3 cm., owing to partial decomposition of the bone. Simultaneously, fibrosis of the corresponding lung field developed in these cases. In these patients with spontaneous rib fractures the bone tolerance dose had been exceeded.

*Cerebral Thrombosis in Sickle Cell Anaemia. D. B. Jelliffe.—p. 38.

Cerebral Thrombosis in Sickle Cell Anemia.—Sickle cell anemia is characterized by a chronic or recurrent hemolytic process and a tendency toward formation of intravascular thromboses. American authors who reported the occurrence of cerebral thrombosis in sickle cell anemia concluded that almost any neurological syndrome may be produced, including coma, hemiplegia, aphasia, and cranial nerve lesions, and they emphasized the importance of examining the blood for sickling in all cases of neurological disease in Negro patients. In this paper Jelliffe describes a girl, aged 4, who had shown signs of general ill health and had become drowsy the day before hospitalization. Despite intramuscular treatment with quinine and procaine penicillin, the child rapidly became more comatose and died. A diagnosis of sickle cell anemia was made, in view of the blood count, slight icterus, rapid development of in vitro sickling, and the presence of in vivo sickling. An associated intracerebral thrombosis suggested by the patient's condition was confirmed at autopsy. Clubbing of the fingers and toes and parietal bossing of the skull have been described as occurring in sickle cell anemia. The radiological appearance of the bosses reveals a characteristic perpendicular spiculated arrangement. The sickle cells seen in this case tended to have a long filamentous shape. This is in agreement with the findings of Foy, Kondi and Brass, who feel that this type of sickle cell occurs only in cases of sickle cell anemia, in contrast to the more compact, regular, half-moon cells seen in carriers of the sickle cell trait. This observation, which requires confirmation, would provide a rapid method of differentiating the two manifestations of sickle cell disease.

Pylorospasm.—The literature on pylorospasm reveals that it occurs almost exclusively in northern latitudes, 10 to 15 times more frequently in boys than in girls, and oftener in breast-fed infants. These and other aspects suggest a spastic genesis produced by insufficient calcium ions, which results in a tendency for tetany to develop. It has been observed that shortly after delivery the calcium content of the serum of many infants is decreased, presumably as the result of deficiency of vitamin D in mother and child. The sex ratio of pylorospasm is similar to that of rickets. Inter-relations between vitamin D and hypophyseal, gonadal, and adrenal hormones also point to disturbances in the calcium metabolism: the parathyroids are larger in females than in males, and the sex hormones influence calcium metabolism. Pylorospasm occurs most frequently during the third week of life when the serum calcium content is the lowest. Pylorospasm is thought to be the result of latent tetany in which vitamin D deficiency, nutritional and endocrine factors are involved. This concept of pylorospasm implies that calcium and vitamin D should be given prophylactically to the expectant mother, particularly near delivery. During the first four weeks the infant should be nursed often, but the amounts given at each feeding should be small. Blood for transfusions should contain heparin but should never be citrated. Infusion of Tyrode's solution and calcium intravenously is recommended. Acid therapy in the form of ammonium chloride and calcium chloride should be accompanied by control of the alkali reserve. If medical therapy fails, surgical treatment in the form of Ramstedt's operation should be resorted to.

*Rare Metastases of Prostatic Carcinoma in Testis, Epididymis and Spermatic Cord. S. Rummelhardt.—p. 231.

Metastases of Carcinoma of Prostate in Testes, Epididymis, and Spermatic Cord.—Reports of metastases of the prostatic carcinoma to the testes have been rare. Four such cases have been reported in the American literature, and Eufinger describes an additional case. In all of these cases the metastasis was discovered during microscopic study of the surgical specimen. Later, in the course of 14 orchidectomies a change indicative of chronic inflammation was observed in one epididymis of one patient and the testis was removed on this side. Microscopic examination of the surgical specimen revealed cancerous infiltration in the spermatic cord and in the epididymis. Such mestatization from the prostate to spermatic cord, epididymis, and testis may take place by the blood or lymph streams or by canaliculi. When orchiectomy is done, the epididymis and spermatic cord should be carefully examined, so that easily removed metastases will not be left behind. Since the testicular metastases were observed neither clinically nor during operation, microscopic examination of the testicular parenchyma should not be neglected.

BOOK REVIEWS

The Prevention of Rheumatic Fever. By Lowell A. Rantz, M.D., Associate Professor of Medicine, Stanford University School of Medicine, San Francisco. Publication number 125, American Lecture Series, monograph in American Lectures in Circulation, edited by Irvine H. Page, M.D., and A. C. Corcoran, M.D. Cloth. $2.25. Pp. 66, with 1 illustration. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1952.

This brief monograph attempts to bring together the information that has accumulated in recent years regarding the role of Streptococcus in rheumatic fever. The author is primarily concerned with presenting evidence indicating the importance of prevention and early treatment of infection by the Streptococcus in the prophylaxis of rheumatic fever. On the basis of such evidence, specific recommendations for the prevention of rheumatic fever are discussed.

This monograph should be of great value to the pediatrician and internist interested in the problems of rheumatic fever. The brevity and simplicity of presentation should increase its usefulness for the student and house officer. With the exception of the small number of persons who still question the role of Streptococcus in rheumatic fever, there is little in the main theme of the subject matter that is controversial. Questions might be raised concerning the specific prophylactic procedures recommended, although most of them seem reasonable; however, the validity of the repeated injunctions against the use of sulfonamides in active rheumatic fever may be doubted. There seems to be no objective data to support this view, although it has been widely accepted by clinicians. This book may not be regarded as a definitive work in the general field of rheumatic fever, and its conclusions may require revision with increasing knowledge; nevertheless, it should serve as a valuable progress report on the present state of knowledge with respect to the control of rheumatic fever.

Case Histories in Psychosomatic Medicine. By Staff of Psychiatric Service, Massachusetts General Hospital, Boston. Edited by Henry H. W. Miles, M.D., Stanley Cobb, M.D. and Harley C. Shands, M.D. Cloth. $4.50. Pp. 306, with 4 illustrations. W. W. Norton & Company, Inc., 101 Fifth Ave., New York 3, 1952.

Selected cases from the clinical conferences conducted by the Psychiatric Service of the Massachusetts General Hospital are discussed from the point of view of this group's experience and approach to the understanding and handling of psychosomatic problems. Emphasis is on expanding psychiatric education, and the necessity of "team work" of psychiatrists, internists, surgeons, social workers, and psychologists is discussed. The book is planned with two chapters of preparatory material. The first chapter, which is concerned with principles and applications of psychosomatic medicine, gives a short review of the anatomic basis of emotional behavior and discusses three mechanisms of emotion, the evidence supporting emotions as a cause of disorders of function, the evidence that emotions may be one of the causes of lesions, selectivity of reactions, and psychophysiological sequences. The second chapter discusses the physician-patient relationship and its role in therapy. Following this are 21 case reports and conference presentations that cover a wide range of psychosomatic problems.

It is questionable whether the introductory chapters would satisfy the psychiatrist, the student, the general practitioner, or a specialist in any field. The chapter on the physician-patient relationship contains several ideas that seem to be used in an unusual way; for example, on page 38, the authors discuss constitutional factors from the physician's side of the physician-patient relationship and base their discussion on the physician's sex, age, and racial or national background. Although these factors are important, it is questionable whether they are constitutional factors.

Some of the conference discussions are disappointing. It is frequently impossible to detect the goals of the physicians taking part in the discussions. It seems as if one discussant is interested in the psychodynamics of the case, another in using the case material to teach, and a third in contributing generally. In addition, there is so much difference in the psychiatric approaches that one becomes confused.

Although the therapy discussed in the book is designated in the foreword as being psychoanalytically oriented, there is little evidence that this is generally so, in spite of the fact that several psychoanalytic formulations are offered. In many instances, the psychoanalytic approach is tied in by simply explaining that the psychoanalyst would use the word "castration" for something that other approaches would call "mutilation." The following quotation appears on page 201: "Some of the concepts developed by psychoanalytic investigations have appeared 'far-fetched' and even ridiculous to some physicians, in many instances because one cannot see explicit confirmation in the material obtained in a few face-to-face interviews." It would seem pertinent to question whether the approach to psychiatric problems by various disciplines is promoted for the student or the nonpsychiatrically trained physician by these demonstrations of how they work together.

Several patients mentioned in the case histories were presented to the staff. On the basis of the records, the presentations seem to have contributed little to the discussions; however, other psychiatrists have found that the presentation of the patient to the group can be beneficial to both patient and physicians.

In many of the case histories, the therapeutic approach seems to be highlighted by a warm, friendly, accepting physician-patient relationship. The role of therapy for patients whose cases are reported as failures therapeutically but who show remarkably beneficial results in the follow-up will be difficult for the beginner to understand. Although the purpose of this book, the need for discussion of the psychosomatic approach, is laudable, this effort does not, in general, achieve its aim.

The Cost of Sickness and the Price of Health. By C.-E. A. Winslow, Dr.P.H., Consultant in Public Health Administration, World Health Organization, Geneva. World Health Organization Monograph Series, no. 7. Paper. $1.50; 7/6; 6 Sw. francs. Pp. 106. World Health Organization, Palais des nations, Geneva; [Columbia University Press, 2960 Broadway, New York 27], 1951.

As part of a program for improved world health, Dr. Winslow, professor emeritus of public health at Yale University, has prepared this monograph as a basis for discussions on the economic value of preventive medicine. His thesis is that mankind suffers from many grave preventable diseases that not only involve human suffering but also impose a heavy burden on the economic resources of the regions involved. Cited studies indicate that "prevention is not only better than cure, it is also cheaper than cure." A recent study by the United States Committee on the Costs of Medical Care covering 9,000 families over a one year period showed that seven days a year were lost on account of illness, exclusive of institutional cases. It has recently been reported that in 1949 the United States had a total national income of $217,000,000,000 of which $10,600,000,000 (5%) was spent on medical and institutional care of the diseased. Any attempt to translate the statistics of life expectancy and disease prevention into terms of financial value to the community is difficult because of demographic differences of various countries.

There seems to be a high correlation between poverty and disease, or as Dr. Winslow states, "Poverty causes disease and disease creates more poverty in a vicious circle." But the prob-

---

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

lem does not end with the elimination of poverty or the creation of a sound financial system. It requires the integration of all the resources of agriculture, industry, economics, and education, with the combined effort aimed at better, more healthful living.

As a consultant to the World Health Organization, the author feels this organization should guide programs and studies in which the more fortunate areas may cooperate with those of less advanced development for the common goal of a healthful, prosperous, and peaceful world. Achievements that have been made in environmental sanitation, control of diseases spread from man to man, promotion of mental health, and promotion of positive health such as maternal and child care and nutrition, are listed and evaluated in areas where such achievement can be more easily measured. Plans, programs, studies, blueprints, outlines, and volumes of good suggestions are, unfortunately, worth very little unless they are financially and socially possible and until they are set in motion, since success is measured by the actual delivery of essential services.

You and Your Aging Parents. By Edith M. Stern and Mable Ross, M.D., Director, Prince Georges County Mental Health Clinic in Maryland. Cloth. $2.75. Pp. 212. A. A. Wyn, Publisher, 23 W. 47th St., New York 19, 1952.

One of the most important dividends of disease control by medical science is the prolongation of lives. Numerically, older citizens are increasing. Accordingly, many problems are confronting the medical profession. Not the least of these is the care of elderly parents. Questions concerning their relationship to their children, living quarters, physical care, and routine living are often the responsibility of their children.

This book discusses, in readable style, over 100 real-life histories that describe situations likely to appear. The book is written particularly for the children. It should be kept in mind that many elderly parents are capable of managing their own affairs: they cannot be classified as problem oldsters; and, as far as possible, they should guide their own destinies.

All too frequently, time brings about diminished resources. These situations are discussed in five sections: (1) the challenge of aging parents, (2) their living apart from their children, (3) their doubling up with other members of the family, (4) bereavements of aging parents, and (5) old age expectancies, safety, and comfort. A number of personal items such as illness and diet are discussed.

In this attractive volume, many families will find helpful suggestions that will enlighten them in their search for adequate answers to vexing problems that arise as their parents grow older. This book gives much detailed information that thousands of families with elderly parents will find of inestimable value.

Anatomy and Physiology for Nurses. By W. Gordon Sears, M.D., M.R.C.P., Physician Superintendent, Mile End Hospital, London. Second edition. Cloth. $2.50. Pp. 395, with 204 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; Edward Arnold & Co., 41-43 Maddox St., London, W.1, 1951.

The author states that in the preparation of the second edition of this text he has aimed to keep the work as simple as possible without sacrificing the scientific and technical approach to the subject. Then he has attempted to include all facts that are essential for examination purposes and for meeting the requirements of the syllabus laid down by the General Nursing Council of England and Wales for the preliminary state examinations. Thirdly, his aim has been to present sufficient facts to make the subject understandable and interesting. And lastly, facts are included that have a subsequent practical application and serve as basic information for the study of other subjects in the curriculum.

The data on anatomy, designed to meet the requirements of students in nursing schools in Britain, may not, in all instances, be sufficiently detailed to serve as an anatomy text for nursing schools in the United States. The material on physiology is not explained and integrated to the degree that is essential if the subject is to be understood and applied in actual nursing practice. While the author states as his aim the promotion of understanding, interest, and ability to apply, his material seems actually to be directed essentially towards presenting facts with which average examination questions can be answered. This is not an uncommon shortcoming of anatomy and physiology textbooks for nurses. While the nursing curriculum does not allow for an extensive study of physiology, there is an urgent need for intensive study of a few basic physiologic principles that are essential in nursing knowledge and practice. While classroom instruction will contribute considerably to greater understanding and integration, a textbook is not fulfilling its purpose if its material does not at least approximate that which will be covered in the classroom.

This book by an English physician includes 15 chapters, each devoted to a system of the body. The style of presentation is almost in outline form. Under some circumstances, this book may be useful as a text on anatomy. It is doubtful if it can be effective as a text or reference on physiology for student nurses.

Untoward Reactions of Cortisone and ACTH. By Vincent J. Derbes, M.D., F.A.C.P., Associate Professor of Medicine, Tulane University of Louisiana School of Medicine, New Orleans, and Thomas E. Weiss, M.D., Instructor in Medicine, Tulane University of Louisiana School of Medicine. Publication number 131, American Lecture Series, monograph in American Lectures in Internal Medicine. Edited by Roscoe L. Pullen, M.D., Director, Division of Graduate Medicine, Tulane University of Louisiana. Cloth. $2.25. Pp. 77. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, 1951.

The authors have been able to crowd a surprising amount of information into this short monograph, which is succinctly worded and excellently documented. The treatise first considers the physiological effects of corticotropin and cortisone and then illustrates how their physiological effects may be exaggerated into untoward reactions by treatment. The authors emphasize that treatment dosage, except in deficiency states, constitutes an unphysiological quantity of hormone, and outline the effects that may occur in various anatomic systems. The salient factors of interest are given in outline form at the head of each chapter; they are then more fully developed in the text. This handling of textual material is a definite aid to study and review. With the exception of the physiological considerations, the ideas concur with present day thought. This book is recommended as an excellent teaching and review text for medical students and physicians.

A Practical Handbook of Midwifery and Gynæcology for Students and Practitioners. By W. F. T. Haultain, O.B.E., M.C., B.A., Hon. Consulting Obstetrician and Gynæcologist, Royal Infirmary, Edinburgh, and Clifford Kennedy, M.B., Ch.B., F.R.C.S.Ed., Assistant Obstetrician and Gynæcologist, Royal Infirmary, Edinburgh. Including Section on The Management of the Infant and Neo-Natal Conditions. By J. L. Henderson, M.D., F.R.C.P.Ed., Professor of Child Health, St. Andrews' University, Dundee. Fourth edition. Cloth. $6. Pp. 412, with 48 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; E. & S. Livingstone, 16 and 17 Teviot Place, Edinburgh 1, 1952.

This edition of this practical handbook of obstetrics and gynecology has been revised extensively, and new material has been added. The chapter on newborn and infant feeding has been brought up-to-date by Dr. J. L. Henderson, professor of child health at St. Andrews' University. A new section on the Rh factor has been written, and the section on venereal diseases has been revised.

The authors discuss modern teaching in this specialty. All the subjects are treated in a concise manner, many in outline form, devoid of nonessential details. Thus, the student or practitioner, for whom this book is intended, can easily obtain essential clinical data and ideas on appropriate therapy. A few carefully chosen illustrations amplify the text.

Although one finds reference to some practices that have become obsolete in the United States, such as uterine douching for hemorrhage, the obstetric and gynecologic teaching is sound and in the best Edinburgh tradition. This handy synopsis can be heartily recommended to students and general practitioners.

Human Biochemistry. By Israel S. Kleiner, Ph.D., Professor of Biochemistry and Director of Department of Biochemistry, New York Medical College, New York. Third edition. Cloth. $7. Pp. 695, with 88 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1951.

In this edition, many chapters have been revised considerably, particularly those sections concerned with mineral metabolism and water balance, respiration and acid-base balance, blood coagulation, and vitamin A function. New material has been added, but, because of restrictions on the size of the book, it was necessary to give only limited space to the discussions.

The topics covered include carbohydrates, lipids, proteins and their metabolism, tissues, milk, blood, urine, enzymes, digestion, vitamins, foods, physiological oxidations, mineral metabolism and water balance, chemistry of respiration and acid-base balance, energy metabolism, hormones, chemical structure in relation to biologic phenomena, and recent clinical applications. The last-mentioned chapter includes brief sections on liver function tests, kidney function tests, dental caries, biochemistry of inflammation, biochemistry of tumors, acid phosphatase and the prostate gland, antibiotics and sulfa drugs, radioactive isotopes, mucolytic enzymes, cortisone and corticotropin (ACTH), and pyrogens.

Each chapter has general and special references that include some of the literature through 1950. The appendix includes a table of standard buffer solutions, one for the composition of foods and another for the sodium and potassium content of foods.

Living in Balance. By Frank S. Caprio, M.D. Cloth. $3.75. Pp. 246. Arundel Press, Inc., P. O. Box 2606, Washington 13, D. C., 1951.

Dr. Caprio, in the preface to his book, states that "one of its purposes is to show how nervous breakdowns can be prevented . . . to teach the reader to achieve better living through better thinking." In a good measure he has succeeded. His style and arrangement is particularly designed to capture the interest of a large group of persons who, knowing little or nothing of the workings of the human mind, wish to learn how mental and nervous illness begins and what can be done about it. Some of Dr. Caprio's concepts and formulations are open to argument, but, generally, he has lucidly and simply discussed, in everyday language, the basic principles that reflect the attitude of present-day psychiatry. The chapter on self-analysis through dream interpretation might well have been omitted.

The chapters on marital situations, sex, fear, alcoholism, and neurotic reactions are written in a manner that will stimulate interest in persons who happen to need advice and guidance. The busy medical practitioner could well recommend this work to a large group of patients who come to him with perplexing problems of everyday living.

Textbook of Biochemistry. By Edward Staunton West, Ph.D., Professor of Biochemistry, University of Oregon Medical School, Portland, and Wilbert R. Todd, Ph.D., Associate Professor of Biochemistry, University of Oregon Medical School. Cloth. $12. Pp. 1345, with 80 illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1951.

This book includes an excellent discussion of the principles of physical and organic chemistry, a feature that is often inadequately discussed in biochemistry texts. These principles are introduced in chapters on gases and solutions, electrolytic dissociation and the mass law, acids, bases, and buffers, osmotic pressure, the colloidal state and membrane phenomena, lipids, carbohydrates, monosaccharides, compound sugars, proteins, nucleoproteins, and nucleic acids. These sections comprise about 30% of the book. Correlation between facts and the underlying principles are repeatedly stressed throughout the book for pedagogic reasons.

The major portion of the text is comprehensive and detailed, with chapters on composition of tissues, enzymes, digestion, absorption, detoxication, bloods and body fluids, respiration, acid-base balance, electrolyte and water balance, energy metabolism, vitamins, biologic oxidation-reduction, intermediary metabolism, organic phosphates in metabolism, chemical energetics, lipid, carbohydrate, and protein metabolism, nutritional aspects of proteins, amino acids, lipids, and carbohydrates, metabolism of inorganic elements, foods, urine formation and composition, hormones, and antimetabolic agents.

There are many formulas, charts, and tables. The numerous tables of composition and values of biologic data compiled in one volume enhances its value as a ready reference work.

The material is clearly discussed, and both general and special references are included. This book is highly recommended to the physician to bring him up-to-date on the status of biochemistry in medicine and to the student who will be able to better appreciate the relationship between apparently isolated biochemical phenomena and general chemical and physical principles.

The Child in Health and Disease: A Textbook for Students and Practitioners of Medicine. By Clifford G. Grulee, M.D., Rush Professor of Pediatrics, University of Illinois, Chicago, and R. Cannon Eley, M.D., Assistant Clinical Professor of Pediatrics, Children's Hospital, Children's Medical Center, Harvard University Medical School, Boston. Second edition. Cloth. $15. Pp. 1255, with illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1952.

This text on pediatrics will be useful to students and general practitioners of medicine. In the preface, the authors give two reasons for sponsoring the second edition: first, medicine is moving so rapidly that the print is scarcely dry before there is something new on the subject; second, new subjects have been incorporated that were not included in the first edition. These subjects, rare in textbooks on pediatrics, include medical supervision in summer camps, cardiovascular surgery, viral hepatitis, erythroblastosis fetalis, and pancreatic fibrosis. The material is printed in two columns on each page. The book is easy to read, and each chapter contains a bibliography. Dr. Grulee's experience as a teacher of pediatrics, as editor of the *American Journal of Diseases of Children* for many years, and his official position with the American Academy of Pediatrics make him particularly well qualified to select the proper authors for the various chapters. A book of this type, which is so up-to-date, should perhaps be made into a loosely bound volume, so that newer aspects and more recent chapters can be added from time to time. This text is an excellent addition to the library of the pediatrician, general practitioner, or student of pediatrics.

Shock Treatments, Psychosurgery and Other Somatic Treatments in Psychiatry. By Lothar B. Kalinowsky, M.D., Research Associate in Psychiatry, College of Physicians and Surgeons, Columbia University, New York, and Paul H. Hoch, M.D., Principal Research Scientist (Psychiatry), New York State Psychiatric Institute and Hospital, New York. Foreword by Nolan D. C. Lewis, M.D., Professor of Psychiatry, College of Physicians and Surgeons, Columbia University, New York. Second edition. Cloth. $8.75. Pp. 396. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1952.

This is an enlarged edition of the only authentic textbook on the place of the physical therapy in psychiatry. A large section on psychosurgery is included in the edition as well as a chapter on theoretical considerations. The extensive research into sources of data, which the authors have critically integrated with their personal experiences, is indicated by the 52 pages of bibliography. The book is well written and the subject matter demarcated to enable easy reference to various aspects of the subject. For psychiatrists employing physical therapy, this work should be a great help.

A Bio-Bibliography of Edward Jenner, 1749-1823. By W. R. LeFanu. Limited numbered edition. Cloth. $16. Pp. 176, with 29 plates. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1951.

This volume consists of a catalogue of the writings of Edward Jenner, the discoverer of vaccination, together with a brief bibliographic sketch and numerous excellent photographic reproductions of original manuscripts and title pages. The book will be of interest largely to book collectors and librarians; however, the general reader will find that it contains much of interest, especially if he is unaware of the wide variety of investigations undertaken by this 18th century scientist, many in collaboration with his teacher and friend John Hunter.

QUERIES AND MINOR NOTES

LABORATORY FACILITIES IN RURAL AREA

To the Editor:—*My clinic in a rural area is 38 miles from the nearest clinical laboratory. We make our own electrocardiograms, x-ray examinations, basal metabolic rate studies, routine urinalyses, blood cell counts, and sedimentation rate studies. It is impossible to obtain a registered laboratory technician; therefore, to obtain chemical analyses, we are obliged either to mail the blood or to send it by bus to the laboratory mentioned, and often the blood is unsuitable for examination by the time it reaches its destination. Furthermore, the accuracy of tests on mailed blood specimens can be challenged. Are there simple, accurate methods of chemical analysis that can be performed by untrained personnel? Is a photoelectric colorimeter simple enough for use by untrained personnel? In mailing the specimens, what preservative should be used? How long will blood keep under mailing conditions? Kindly discuss this in relation to such determinations as nonprotein nitrogen, urea nitrogen, blood sugar, chloride, sodium, cholesterol, and protein levels, and liver function tests. I believe this to be an acute problem in rural practice, especially since we younger men are attempting to establish the same high standards of medical care that prevail in larger cities.*

J. J. Kirschenfeld, M.D., Fort Deposit, Ala.

Answer.—Whether it is logical to establish a routine blood chemistry laboratory in a rural clinic when it is impossible to obtain a registered laboratory technician is not a simple question; however, if an adequate clinical laboratory is available within 38 miles, it would appear that it would not be logical. There are many advantages that rural areas do not have, including brain surgeons, laboratories for cardiac catheterization, and general clinical laboratories. There are no simple, accurate, and foolproof methods for chemical analyses, and chemical analyses cannot be performed by untrained office personnel. Photoelectric colorimeters are highly technical instruments and require constant attention by someone skilled in their use, and highly trained personnel are needed to calibrate them. If the clinical laboratory referred to is within 38 miles of the rural clinic, it would appear that a satisfactory arrangement could be made with the laboratory for examining and reporting on specimens. This presupposes that the laboratory is competent. There are anticoagulants that have been described as being satisfactory for shipping specimens by mail. They vary with the test to be performed and the method used. Sodium fluoride and thymol will preserve specimens for sugar determinations and many other tests but cannot be used for urea. Sodium oxalate can be used when urea is to be tested.

STIMULATION OF GROWTH

To the Editor:—*A 15-year-old boy is only 5 ft. 1 in. (154.9 cm.) tall. His physical development is entirely normal, except for his height, which is partly a family characteristic. Would hormone therapy help his growth?*

N. B. Livingston Jr., M.D., Mohall, N. D.

Answer.—The patient should be carefully studied from a general medical and endocrinological point of view. Roentgenograms should be taken of the bones of the elbow, hands, and knees to see whether epiphyseal closure has occurred and to estimate the growth potential remaining in the skeleton. If the epiphyses are closed, future growth is impossible. If they are open, the degree of potential growth can be estimated by careful study. If the patient has hypothyroidism, the administration of desiccated thyroid will stimulate growth. If his basal metabolism is within normal limits and he is maturing sexually at a satisfactory rate, no form of therapy will be effective. If the patient is sexually immature, growth of the skeleton can be stimulated by the administration of chorionic gonadotropin or androgen. Androgen is not a substitute for the thyroid hormone or for the growth hormone of the pituitary, without which the skeleton cannot attain normal length. Roentgenograms of the sella turcica should be made to exclude the presence of a pituitary tumor. The growth hormone of the pituitary is not very effective in stimulating growth in man.

LOSS OF HAND FUNCTION

To the Editor:—*Please give an opinion on the percentage loss of function of a hand in which there remains a good functioning thumb, two-thirds of the middle finger, slightly over one-half the ring finger, and a little over one-half the small finger. The patient closes his hand with some difficulty because of residual swelling in the palm and in the amputation stumps.*

M.D., New York.

Answer.—Since there is no uniform system of rating disability in all states in this country, it is difficult to give an opinion on the percentage loss of function of this hand. Although it may be possible to ascribe a certain percentage of disability based on the loss of part or all of certain digits, a major factor in considering the percentage loss of function should be the particular loss of function that has resulted in this case. Before establishing a permanent disability rating, it should be determined whether further improvement in the usefulness of the hand can be obtained by the use of rehabilitative procedures, including physical therapy and occupational therapy. The patient's occupation should also be considered in determining the amount of final disability. Assistance in determining the percentage loss of function may need to be obtained by reference to tables of disability acceptable to the various parties having an interest in this particular case. The complexity of the problem of determining the percentage loss of function of a hand is apparent in an excellent discussion of this subject that appears in the book "Accidental Injuries" by H. H. Kessler (ed. 2, Philadelphia, Lea and Febiger, 1941).

ELECTRIC SHOCK TREATMENTS

To the Editor:—*Some of my patients with melancholia were given electric shock treatments years ago, but I was discouraged by the violent reactions produced and the uncertain results. Do the later type machines produce the violent convulsions produced by the older types, and do they produce better results?*

W. B. Chapman, M.D., Joplin, Mo.

Answer.—Electric shock therapy involves the application of electric currents to the head. These currents usually vary from 300 to 1,200 ma., produced by voltages of from 70 to 150 volts, and current passage times of 0.1 to 0.5 seconds are used. The purpose of the application of these currents is to produce a convulsive seizure. The dose required for production of the convulsive seizure varies from patient to patient and must be determined by the person applying the treatment. The use of an electrical device in shock therapy is advantageous in that application is simple and it is possible to induce either minor or major seizures. Modifications in the older type machines have been made, but the machines still produce a convulsive seizure.

Some use has been made of tubocurarine chloride to reduce the contractile power of the skeletal muscle in conjunction with electric shock therapy. For shock treatment as used in psychiatry, New and Nonofficial Remedies (Chicago, American Medical Association, 1952, p. 431) gives the usual dose of tubocurarine chloride as 3 mg. (20 units) for each 40 lb. (18.1 kg.) of body weight. Usually, for greater safety, a smaller dose is used initially.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

ASYMPTOMATIC NEUROSYPHILIS

To the Editor:—*A woman, aged 45, is symptom-free from latent syphilis. Her weight has not changed in 10 years. She gives a history of latent acquired syphilis of 22 years duration. In 1950, her husband developed cerebral spinal syphilis with paresis. At that time she sought treatment and was given 600,000 units of penicillin daily for 15 days. On Jan. 17, 1952, a blood serum test was strongly positive (4+) for syphilis. The results of a spinal fluid examination were as follows: quantitative reaction to Wassermann test, 444; 1 white cell per cubic millimeter; the globulin level was normal, the total protein content being 19 mg. per 100 cc.; and the colloidal gold test reaction was 1122100000. What treatment is indicated for this patient? Should treatment with a saturated solution of potassium iodide be continued?*

M.D., Pennsylvania.

Answer.—If the patient described has not yet been examined by a skilled neuropsychiatrist, such a consultation should be promptly requested. If the results of his examination are normal, the patient may be considered as having asymptomatic neurosyphilis. If the latter proves to be the correct diagnosis, the patient is not in need of further treatment. The spinal fluid apparently was not examined before the patient received treatment. On examination 8 months after the administration of 9 million units of penicillin, the spinal fluid is "inactive" in the sense that the cell count and protein content are normal. The normality of these two tests indicates that whatever inflammatory component of the asymptomatic neurosyphilis may have been present when treatment was started has now been adequately dealt with. There is a 90 to 95% certainty that this result will be permanent. Nothing is gained by the administration of potassium iodide, arsenic or bismuth, or, for the time being at any rate, additional penicillin therapy or fever therapy.

The patient should be followed from this point with repeated physical (especially neuropsychiatric) examinations and with recheck examinations of the blood serum and the spinal fluid at intervals of every 6 months for the next 3 years, at yearly intervals thereafter for another 3 years, and at somewhat longer intervals after that. Indications for retreatment will be the appearance of clinical signs or symptoms of neurosyphilis of any type or the reappearance in the spinal fluid of an increased cell count and/or protein content. The persistence of a positive complement fixation test and/or flocculation test in the blood and spinal fluid may be ignored as long as the patient's physical condition and the cell count and protein content of the spinal fluid remain normal.

UNDESCENDED TESTES IN YOUNG BOY

To the Editor:—*What is the consensus regarding treatment of a 3-year-old boy with bilateral undescended testicles? The boy is otherwise well developed, but the testicles cannot be palpated either in the scrotum or in the canals. The penis is extremely small and was noted as being very small at birth. The pregnancy and delivery were uneventful. Other siblings are normal, as are the parents.*

M. E. Friedman, M.D., New Buffalo, Mich.

Answer.—The following point of view is the one most generally accepted concerning the treatment of undescended testes: 1. Accurate diagnosis is important. The patient should be examined at least twice in both the upright and recumbent positions to ascertain the exact location of the testis. 2. The earlier the testis is brought into the scrotum the better its function in later life. The testis cannot function normally except in the environment of the scrotum. The longer it remains at some level above the scrotum, the greater the likelihood of permanent damage. 3. Glandular treatment should be instituted as soon as it is practical to carry out operative procedures so that these may be used if glandular therapy is not effective. This means that treatment should be started by about the age of 3 years. 4. The material of choice is chorionic gonadotropin. It should be given in a dose of 500 I. U. by intramuscular injection 3 times a week. In patients with bilateral undescended testes, chorionic gonadotropin may be ineffective. Under these circumstances, testosterone propionate should be given in a dose of 25 mg. 3 times a week by intramuscular injection. 5. If glandular therapy is effective, descent will usually occur within eight weeks. If the treatment is ineffective, operative procedures should be carried out at once by some one specially skilled in this field. Great care must be taken to preserve the blood supply of the testis. Glandular therapy should be continued until the time of operation. 6. Only a small amount of genital growth should be induced. This means that chorionic gonadotropin and testosterone propionate should not be continued for a long period of time in a young boy.

FERTILITY IN MEN

To the Editor:—*What effect, if any, have the following on fertility in men: (a) inhalation of carbon tetrachloride, (b) high altitude flying, (c) inhalation of fumes of the galvanizing process, (d) exposure to radar waves, as experienced by naval personnel who are in fairly constant contact with them, and (e) infectious hepatitis?*

Norman L. Wilson, M.D., Quincy, Mass.

Answer.—(*a*) Inhalation of carbon tetrachloride does not cause male sterility. The liver detoxicates this chemical. (*b*) High altitude flying over long periods of time has not been proved to cause male sterility. Modern airplane cabins have both pressure and oxygen control for human safety. (*c*) In the galvanizing process, iron is coated with tin and is then immersed in a zinc bath. Physiological damage from exposure to this process would be the same as occurs in lead or zinc poisoning. Progressive anemia may occur and may result in temporary or permanent sterility. (*d*) Exposure to radar waves does not cause sterility. Radar waves are high frequency electromagnetic radiation and may have the same frequency as short-wave or ultrashort-wave radio waves. They do not produce ionization within tissues and cannot cause sterility. The alpha, beta, and gamma rays generated by radioactive substances, such as radium, or by x-ray apparatus are the three types of rays usually considered in the problem of sterility. The gamma rays are those that produce sterility; the beta rays, it is believed, probably do not produce sterility; the alpha rays cannot produce sterility. (*e*) In infectious hepatitis as a primary infection of the liver, secondary sites of infection may develop as a result of invasion by the infecting organism, after its transmission through the blood stream. Orchitis may result, with unilateral or bilateral sterility, depending on the severity of the attack and the extent of involvement (one or both testicles). Mechanical blocking of the vas deferens by invading organisms, such as filariae and amebas will prevent egress of spermatozoa from the vas deferens, causing male sterility. High body temperatures sustained over long periods of time can destroy the ability of the testes to manufacture spermatozoa.

DIATHERMY IN REGION OF METALLIC IMPLANTS

To the Editor:—*A patient with several silver wires in her fractured patella needs short wave diathermy for her arthritic knee. Is it dangerous to apply diathermy to bones with silver wires in them? Is there a type of diathermy (for instance, diathermy by Microtherm®) that can be applied with safety?*

M.D., New York.

Answer.—Both short wave and microwave diathermy, which are effective in heating human tissues, are even more effective in the heating of metals. For this reason, it is generally felt that in any condition in which metallic implants are present near the area or in the area to be treated, short wave and microwave diathermy are contraindicated. Metallic substances, such as bullets, screws, bands, and wires in tissues may be excessively heated if diathermy is applied. It is known that, in many instances, damage has not occurred, but there is a potential danger, both actual and theoretical, which makes it advisable to heat these areas by means other than medical diathermy.

PENICILLIN INJECTIONS

To the Editor:—*In* The Journal, *June 28, 1952 (page 906), the answer to the query about penicillin injections contains a serious error. It suggests the use of "two injections a day of 300,000 to 600,000 units of crystalline penicillin G or K." A number of years ago it was conclusively shown that penicillin K was relatively ineffective in almost all infectious diseases. It is not obtainable commercially, and all penicillin manufacturers make every effort to remove penicillin K from their products. The only penicillins now commercially available are penicillin G and penicillin O in the form of one or another of their salts. The answer is further at fault in that it makes no distinction between repository preparations of penicillin G and aqueous solutions of crystalline penicillin.*

FLUORIDE BY MOUTH DURING PREGNANCY

To the Editor:—*In answering the question of whether fluoride given to the mother by mouth during pregnancy will cause the baby to have better teeth in life, it is stated that there is no evidence that fluoride taken by the mother during pregnancy will cause a baby to have better permanent teeth* (J. A. M. A. *March 1, 1952).*

In the April, 1951, Journal of Dental Medicine, *Dr. Reuben Feltman of Passaic, N. J., writes "Since 1948, 309 children have been born to mothers who have ingested tablets containing 2 to 4 mgms. of Calcium fluoride daily. Some of the children who were born from these mothers have been examined. The results to date are most heartening,—the numbers are too small and the ages too young to be of importance at this stage of the investigation.*

"This much can be reported, the caries rate in three year olds in this area is two decayed teeth. Caries has been found in only one child. The enamel has the appearance of the inside of an oyster shell highly polished and pearly."

The following quotation is from "Industrial Fluorosis: A Study of the Hazard to Man and Animals Near Fort William, Scotland" (Medical Research Council, Memorandum no. 22, London, His Majesty's Stationery Office):

"Evans Phillips and Hart (1938) suggested that fluorine is transferred through the placenta of the cow to the foetus. Velu (1936) held that fluorine in young animals born of mothers exposed to fluorine must have passed to the foetus. Knouff (1936) confirmed the passage of fluorine through the placenta of bitches."

Ample evidence has been compiled from the literature to lend feasibility to the theory that fluorine ingested during pregnancy and the formative years of tooth development will cause a reduction in the incidence of dental caries. There is a maternal transference of fluorine, which makes both the deciduous and permanent teeth less subject to caries if the child continues to get the optimum daily dose regularly.

David W. Bronson, D.D.S.
200 W. 40th St.
New York 18.

o the Editor:—*A question concerning the effect of fluoride given by mouth during pregnancy was answered in your column in* The Journal *of March 1, 1952, with the statement that "the tooth buds of the permanent teeth are not even formed at the time of birth [so] it is difficult to see how fluoride can affect the baby's future teeth in utero."*

According to J. A. Salzmann (Principles of Orthodontics, Philadelphia, J. B. Lippincott Company, 1943, p. 182) epithelial buds are present for the permanent incisors, cuspids, bicuspids, and first molars at the time of birth, and differentation of the tooth germ has so far advanced that calcified tissue is found in the germ of the maxillary and mandibular first permanent molars. The permanent mandibular first incisor also shows calcification. The tooth germ of the permanent maxillary first incisor and the permanent mandibular second incisor have reached a high degree of development. The precursors of the other teeth listed above are described as small undifferentiated buds at this stage.

It would seem, therefore, that the failure of ingested fluoride to affect the baby's teeth in utero must depend upon some mechanism other than the lack of permanent tooth buds in the fetus. Such failure, it is not inconceivable, may even be apparent rather than real and due to difficulties in assembling and evaluating clinical material.

PAINFUL FEET

To the Editor:—*I would like to add the following aids that I have found valuable in the treatment of metatarsalgia to that described in* The Journal *March 8, 1952 (p. 877):*

1. The use of carpeting with foam rubber underpads to provide a soft walking surface in the home or office. 2. The addition of an extra leather sole to the shoe. This helps tremendously to give a cushioned effect to the sole of the shoe. 3. Application of metatarsal bars to the shoe. I have found it best to make and apply these myself.

H. C. Goldberg, M.D.

PROGRESSIVE MYOPIA IN A CHILD

To the Editor:—*In the query concerning progressive myopia in a child in* The Journal *March 29, 1952 (page 1165), a statement was made that "The amount of correction of myopia has no effect on the progress of the refractive error." I agree that in some young patients who abuse their eyes, myopia cannot be checked even with the strongest glasses; however, in most cases the progress of myopia can be decreased by the use of full correction eyeglasses. This favorable outcome is significant socially, particularly for girls. If the myopia can be checked at the strength of three diopters, attendance at formal functions later in life will be possible without eyeglasses.*

I disagree with the philosophy that "There need be no insistence on the wearing of the glass unless clear vision is preferred by the patient." This erroneous concept is contrary to the concepts of modern preventive ophthalmology and may explain why some physicians do not refer young myopic patients for refraction until complaints of poor vision are recorded by the school authorities. The progress of myopia is accelerated when the indifference suggested in the reply is practiced. Normal or 20/20 vision must be demanded by all practitioners and not left to the whims of children or their parents.

Teachers in the field of eye muscle dysfunctions know that in young myopic patients with accommodative exophoria who fail to wear eyeglasses constantly the muscle imbalance may be aggravated and divergent strabismus may develop. In a series of cases previously reported (Smith, J. W.: The Problem of Strabismus in Childhood, with Especial Reference to Convergent Strabismus in Infancy and Early Childhood, Am. J. Ophth. **31:**85 *[Jan.] 1948), 10% of patients in early stages of divergence were restored to orthophoria by continually wearing eyeglasses to correct their myopia.*

It is regrettable that authorities are not in agreement regarding the treatment of myopia. In my experience, extending over thirty years, early and full correction and insistence on the constant wearing of the glasses during the school years is the regimen that pays dividends in good eye health. This plan insures the minimum of progression and in many cases actually arrests the myopia.

DISEASES OF THE AGED

ANALYSIS OF PATHOLOGICAL OBSERVATIONS IN 1,251 AUTOPSY PROTOCOLS IN OLD PERSONS

Leon S. Medalia, M.D.
and
Paul D. White, M.D., Boston

For the first time in history, the average expectation of the duration of human life at birth has passed the Biblical mark of three score and 10 years. This applies to a girl born in the United States today; a boy has an expectation of about five years less. This sex difference in longevity is a characteristic found throughout the animal kingdom and may prove to be an insurmountable law of nature. It is gratifying to know, however, that the duration of human life has steadily and rapidly increased during the past two generations for both sexes. Coincident with our gaining control primarily over the infectious diseases in the majority of persons, both young and old, a heavy responsibility has devolved on us to study and to lessen, as far as we are able, the progress and effects of the chronic, so-called degenerative diseases, mainly those involving the heart and blood vessels, in the earlier old age decades as well as to combat malignant neoplastic disease. If we can eventually make possible the maintenance of reasonably good health in our fellow citizens up to the age of perhaps 90 and can utilize their accumulated experience, knowledge, and wisdom, the world will be a better place in which to live. In order to make a start in this worth-while, indeed essential, effort, we must establish a baseline of knowledge of the incidence of diseases in the aged, for adequate information in this area is still very scanty. This paper is an initial effort to record more accurate data on the incidence of the diseases of older persons than have been hitherto available.

At the time this study was finished and was ready for publication (January, 1950), we had found only one reference in the literature that was in any way related to our work—an article published in 1949 by Trevor Howell.[1] He reported the pathological observations in 240 patients who were 80 years old and over made in a large general hospital in London. No comparisons were made by him between data for this group and those of other age decades. As an illustration of the paucity of such studies in the literature he quotes Sherlock Holmes: "I have no data yet. It is a capital mistake to theorize before one has data. Insensibly one begins to twist facts to suit theories, instead of theories to suit facts." It was this lack of data in the literature that held up our publication of this article. We believed our inability to find any references in the literature pertaining to our work was due to the lack of a proper search, so we continued searching.

In a recent article entitled "Morbid Anatomy of Old Age," Trevor Howell begins by saying, "There is as yet little knowledge concerning the morbid anatomy found in aged patients."[2] In this article he reports the pathological observations in 25 patients aged 90 or over and in 90 patients between the ages of 80 and 89. In both series he deals with the description of the pathological conditions. He makes no comparisons between the patients of different decades nor between men and women; however, it is a worth-while study, and the cumulative reports of such studies, we believe, will be of great value in the future.

Rosenthal and Feigin [3] give no statistical data on their observations in patients of different age groups. On the other hand, they quote Philo, who, in the same hospital, studied cancer of the prostate in 1,081 patients on whom autopsies were done. He reported his observations according to the patients' ages by decades from 40 years old and over, thus providing material for comparison. Monroe [4] recently published a survey of the records of the patients 61 years old and over who were treated at the Peter Bent Brigham Hospital from its opening in 1913 to 1943. Although he states that some of the information given in the records was verified by autopsy, his report is

Myocardial infarcts were found in only 2.5% (6 men and 4 women) of the 406 patients with normal heart weights, although 47 others (28 men and 19 women) showed myocardial scarring; in contrast, 13% (70 men and 42 women) of the 845 persons with abnormal heart weights had myocardial infarcts, and 197 more (114 men and 83 women) showed myocardial scarring. Myocardial infarcts and scarring occurred with little difference in frequency in patients in all four decades (fig. 2).

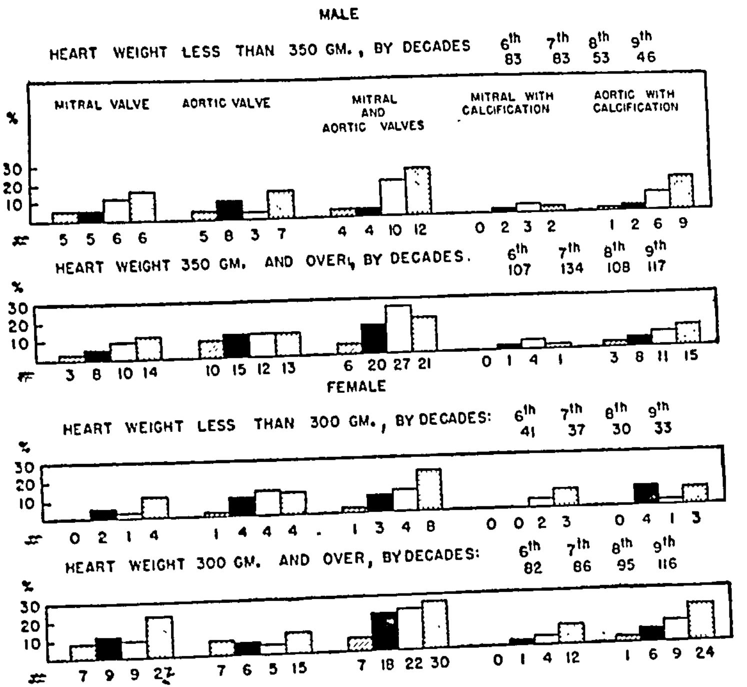

Fig. 5.—Incidence of valvular sclerosis in the 1,251 patients whose autopsy protocols were analyzed (arranged as in figure 2).

Aortic atherosclerosis without calcification (fig. 4) dedecreased in frequency of occurrence in successive decades in both men and women with hearts of normal weight; for example, it occurred in about 65% of the men in their sixth decade compared with 40% in their ninth decade and in about 60% of the women in their sixth decade compared with 28% in their ninth decade. Aortic atherosclerosis with calcification, however, increased in occurrence in successive decades in both men and women with normal heart weights, increasing from 12% of the men in their sixth decade to 55% in their ninth and from 10% of the women in the sixth decade to 75% in their ninth. There was much less difference in the incidence of aortic atherosclerosis either among the decades or between the sexes in patients with increased heart weights.

Valvular sclerosis with or without calcification, especially basal, (fig. 5 and 6) was seen occasionally, occurring increasingly with advancing age. It occurred in either the mitral or the aortic valve or, more frequently, in both, whether or not the heart weight was increased. Recognizable rheumatic heart disease was rare, being diagnosed in only 16 (5%) of 313 patients in their sixth decade, in 17 (5%) of 340 patients in their seventh decade, in 10 (3.5%) of 286 patients in their eighth decade, and in 8 (only 2.5%) of 312 patients in their ninth decade.

Hypertension in slight degree was not a rare condition, especially in the case of persons with hearts that were heavier than normal, but it did not vary much in occurrence either in the decades or between the sexes. There were 165 (13.2%) patients with slight hypertension and abnormally heavy hearts and only 33 (2.5%) with slight hypertension and hearts of normal weight. Fewer patients had moderate hypertension, which again was much commoner among those with heavier hearts, 116 (9%) patients being affected, than among those with hearts of normal weight, 18 (1.5%) patients being affected. Marked hypertension was rare in these older age patients, confirming the clinical impression that malignant hypertension is a disease primarily of youth and middle age; it occurred in only 35 patients (2.8%) altogether, of whom all except 2 had abnormally heavy hearts and only 23 were over the age of 60.

Cerebral vascular accidents occurred oftenest in patients under age 70, affecting 67 (5.4%) patients altogether, only 21 of whom were over 70. Only 2 of the latter 21 patients had hearts of normal weight, but 24, or slightly over one-half, of those under age 70 had hearts of normal weight. The cases were about evenly divided between the sexes, occurring in 35 men and 32 women. Acute pericarditis was seen in 100 (8%) patients in all, of whom 66 were men and 34 were women. All decades were represented, from 22 patients in the sixth to 23 in the ninth, but there was a considerable minority of patients (only 19 of the 100) whose hearts were not overweight. Cardiovascular syphilis (fig. 4) was surprisingly rare, being found in only 51 (4%) patients altogether. Forty of the patients were men, and only 20 patients had hearts of normal weight. Only 3% (23 men and 15 women) of the total number of patients had aortic aneurysms.

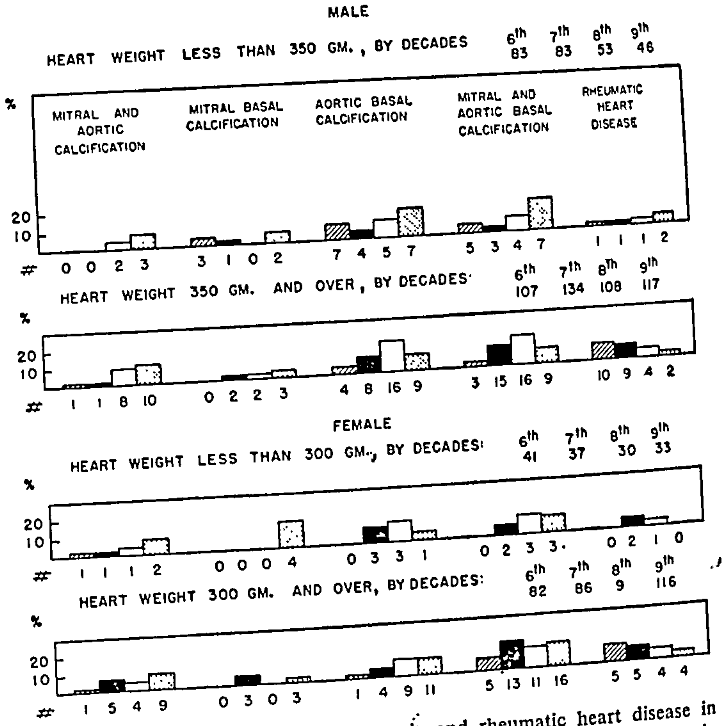

Fig. 6.—Incidence of valvular sclerosis and rheumatic heart disease in the 1,251 patients whose autopsy protocols were analyzed (arranged as in figure 2).

Nephrosclerosis was common, being diagnosed in 460 (37%) patients. Its prevalence increased with increasing age, occurring in 71 patients in their sixth decade and in 171 in their ninth. There was no appreciable difference in its occurrence in the sexes (remembering that men outnumbered women in the total series 7 to 5), 249 men and 211 women being affected. There were 121 (about 25%) of these patients whose hearts were not overweight. In contrast to arteriosclerotic nephritis (nephrosclerosis), other kidney diseases were relatively rare. There were only 16 patients who had nephritis as such and 105 who had pyelonephritis, of whom 68 were men and 37 were women. Cystitis occurred in 134 (11%) patients, and was seen more often in the men (86) than in the women (48).

Noncardiovascular Diseases.—Of noncardiovascular diseases, bronchopneumonia (fig. 1) occurred oftenest, affecting a total of 449 (36%) patients, the number affected increasing with increasing age from 81 in their sixth decade to 147 in their ninth. There was an uneven sex distribution, with 270 men and 179 women affected. Lobar pneumonia was relatively rare; there were only *51 (4%)* cases altogether, 38 in men and only 13 in women. Next in prevalence was cancer (fig. 1), with 303 (24%) patients affected, 68 in their sixth decade, 83 in their seventh, 85 in their eighth, and 67 in their ninth. The distribution of cases by sex was even for the series, with 167 in men and 136 in women. The majority of these patients (160) had hearts of normal weight or below. Active tuberculosis (fig. 1) was rare, occurring in only 117 patients altogether, with 39 in their sixth decade, 30 in their seventh, 34 in their eighth, and only 14 in their ninth. It was commoner in the men (78) than in the women (39) and occurred oftener in persons with normal heart weight (71) than in those with abnormal heart weight (46).

Blood diseases, chiefly anemia, were rare, affecting only 35 patients altogether, 22 women and 13 men. Cirrhosis of the liver was rare, occurring in 107 patients (64 men and 43 women). It was commonest in patients in their sixth decade (35) and showed no particular relation to heart weight. The occurrence of cholecystitis increased with increasing age, affecting 17 patients in their sixth decade, 37 in their seventh, 43 in their eighth, and 61 in their ninth. Women were affected oftener than men, numbering 100 and 68, respectively. Peptic ulcers (fig. 1) were rare. Only 43 patients (29 men and 14 women) had duodenal ulcers, and only 39 (22 men and 17 women) had gastric ulcers. The total of 82 patients made up only 6.5% of the entire group. .

CONCLUSION

This survey of 1,251 autopsies of aged persons has brought to light some well known and some rather surprising indications of disease incidence in old persons. This study indicates the need for further analyses of this sort to establish a firmer foundation for the appraisal of measures for the medical care and the prevention of disease in the increasing number of old persons. Social, economic, and educational as well as medical advances are to a certain degree dependent on this increasing knowledge.

264 Beacon St. (Dr. White).

DUODENAL ULCER

RESULTS OF TREATMENT WITH SUBDIAPHRAGMATIC VAGUS RESECTION AND GASTROENTEROSTOMY; INTERIM REPORT

Stanley O. Hoerr, M.D., Charles H. Brown, M.D., Eugene W. Rumsey, M.D.
and
George Crile Jr., M.D., Cleveland

The physiological basis for the use of vagotomy in the treatment of duodenal ulcer rests on two findings: (1) patients with duodenal ulcer have increased nocturnal gastric secretion of hydrochloric acid and (2) complete vagotomy abolishes the increased secretion.[1] Excellent clinical results from the use of subdiaphragmatic vagotomy with gastroenterostomy in duodenal ulcer have been reported by Dragstedt, Crile, and others.[2] An unpublished report of a nation-wide survey conducted by the vagotomy committee of the American Gastroenterological Association in 1950 cited excellent results from the operation in nearly 98% of the patients. Other reports have indicated an unsatisfactory experience with the operation, and the 1951 report of the committee mentioned above was less impressive than that of the preceding year, although there were still about 94% of patients satisfied with the results of the operation.[3]

Because of these conflicting views, further studies on the long-term results of the operation are desirable to form a basis for critical comparison with results from other procedures, such as gastric resection. In this connection, a report of the present condition of 147 patients who have been followed from two to four years after vagus resection with gastroenterostomy for duodenal ulcer is presented.

From the Cleveland Clinic Foundation and Bunts Educational Institute.

MATERIAL

The study is based on the hospital records and the answers to questionnaires received from a group of 147 patients who were operated on between September, 1946, and March, 1949, at the Cleveland Clinic Hospital. Since seven additional patients operated on during this period could not be traced, the follow-up is 95% complete. Two years had elapsed since operation for 78 patients, three years for 53, and four years for 16. These patients had physical evidence of a duodenal ulcer at the time of laparotomy in nearly every instance; in the few cases in which it was not demonstrated, there was roentgenographic evidence together with a consistent clinical history. The questions submitted to the patients were as follows:

1. Have you had any recurrence of ulcer pain since your operation?
2. Have you had any other abdominal distress? If so, describe.
3. Have you had any diarrhea? If so, how many stools a day on the average?
4. To your knowledge, has hemorrhage from the stomach occurred since operation?
5. What is your present weight?
6. How is your appetite (good, fair, poor)?
7. Are you satisfied with your operation?
8. Are you able to work or perform your usual duties?

Table 1.—*Age Distribution of Patients*

Age, Yr.	No. of Patients
20-29	6
30-39	25
40-49	48
50-59	53
60-69	14
70 plus	1
Total	147

Table 2.—*Duration of Symptoms*

Duration, Yr.	No. of Patients
1 or less	3
2-4	17
5-9	36
10-14	28
15-19	21
20 plus	42
Total	147

Table 1 gives the age distribution. It will be noted that approximately half the patients were less than 50 years of age. Some believe that in the older patients a gastroenterostomy alone will give a good clinical result but that in the younger patients a high incidence of marginal ulceration is to be expected if a vagotomy is not performed at the same time. (The experience of the Cleveland Clinic is that age is not an important factor in the development of marginal ulceration.) Table 2 shows the duration of symptoms. It may be seen that ulcer symptoms had existed for many years in the great majority of patients and that these patients, by inference, had had years in which to try the effects of a medical regimen.

INDICATIONS FOR OPERATION

A review of the records of the 147 patients shows that the indications for surgery were strict. The percentage of patients who are operated on for duodenal ulcer and its complications at the Cleveland Clinic, in comparison with the total number treated for this disease, has remained remarkably constant in recent years, varying from 10% to 15%. During the period studied, approximately 13.5% of the patients with duodenal ulcer were treated surgically. The policy at the Cleveland Clinic has been to regard duodenal ulcer as fundamentally a "medical" disorder and to recommend surgery only for those patients who have had one or more of the major complications or who have had repeated and incapacitating recurrences of activity of the ulcer.

Table 3 lists the primary indication for surgery, as well as previous complications and weight loss in each main group. It is seen that in the group of 75 patients operated on primarily for "intractability" there were 11 who gave a history of hemorrhage from the ulcer; eight had a history of a previous perforation, and two had had obstruction. When these 21 patients are added to the 56 who were operated on for obstruction and 14 who were operated on for hemorrhage, the number of patients who had had one or more of the major complications of ulcer totals 91 (63%). The 14 patients who were operated on because of hemorrhage had surgery during a quiescent interval. (Vagus resection with gastroenterostomy is not advisable during active bleeding; if emergency surgery must be done, the procedure of choice is a direct ligation of the bleeding vessels in the ulcer bed and a subtotal gastric resection.) The two patients in whom operation was undertaken for suspected neoplasm had roentgenographic evidence suggestive of gastric carcinoma; the duodenal ulcer in these two was disclosed at operation.

Table 3.—*Indications for Operation*

Principal Reason for Surgery	No. of Patients	Other Complications, No. of Patients			
		Weight Loss of 10 Lb. (4.5 Kg.)	Previous History of		
			Hemorrhage	Obstruction	Perforation
Intractability	75	6	11	2	8
Obstruction	56	22	15	..	5
Hemorrhage	14	2	..	1	0
Neoplasm (?)	2	1	0	0	0

OPERATIVE PROCEDURE

The operation carried out on these patients was a subdiaphragmatic division of the vagus nerves (segments always being sent to the pathologist for subsequent microscopic verification), together with any accessory fibers that could be found, and a short loop posterior gastroenterostomy. During the period covered by this report other operative procedures were performed for duodenal ulcer, but these are not included in this analysis. The largest group comprised some 50 patients who had vagotomy and a pyloroplasty instead of a gastroenterostomy. There were a few who had a gastric resection with the vagotomy, several who had only a vagotomy without an accompanying drainage operation, and three instances of unilateral vagotomy among the earliest cases in which a posterior branch of the vagus was not found.

In a series of 397 patients undergoing the procedure through Oct. 1, 1951, there were two operative deaths, a mortality rate of 0.5%. There have been no deaths in the last 159 patients. It would seem that operative mortality should not exceed 1%.

POSTOPERATIVE DIARRHEA

It is difficult to ascertain the significance of diarrhea from answers to the questionnaires (table 4). In only four patients was the diarrhea a troublesome daily event, and in at least one of these patients diarrhea had existed before the operation.

RESULTS

It is worth while noting that the routine management of these patients after operation did not include antacids or antispasmodics. After six weeks on a bland diet, the patient is told he may eat when he pleases and what he pleases, and smoking or drinking in moderation is permitted. This is in sharp contrast to the rigid ulcer schedules employed by some surgeons after a gastric resection for duodenal ulcer.

Very strict criteria were employed in the appraisal (see figure). An "excellent" result means that the patient has no gastrointestinal complaints, takes no medicaments, follows no dietary restrictions, pursues his regular occupation, and himself regards the operation as an unqualified success. In this classification there were 101 patients (69%). Nine of these patients recorded a very occasional, mild diarrhea, which required no treatment.

TABLE 4.—*Incidence of Diarrhea After Operation*

Degree Diarrhea		No. of Patients
Not troublesome		16
Infrequent and mild	11	
Daily and mild	5	
Troublesome		14
Infrequent	10	
Daily	4	
Transient (in hospital only)		3
Total		33 (22% of 147)

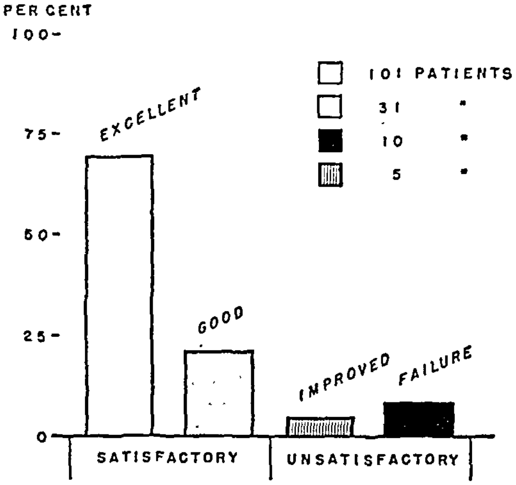
A "good" result was one in which the patient had occasional vague digestive complaints, such as gas, bloating, or upper abdominal distress. Ulcer pain was not present. Regular medication was not needed, and the usual occupation could be followed. Some of these patients undoubtedly suffer from the irritable colon syndrome, and some are mild neurotics who would never be in excellent health under any circumstances. All these patients regarded themselves as improved by the operation, and all but a few were completely satisfied. When "good" results are added to the "excellent" results, there are 132 patients, or 90%, in whom the operation may be termed successful.

Five patients continue to have partially incapacitating gastrointestinal disturbances, but so far as we could determine there was no clinical evidence of recurrent ulceration. These were classified as "improved." Psychic factors seemed to play a large role in the unsatisfactory result.

There are 10 patients in whom treatment failed. Four of these patients had subsequent operations, resulting in the relief of symptoms in two; the condition in four of the remaining six is satisfactorily controlled with a medical regimen. There are thus four whose present condition as it relates to the ulcer is unsatisfactory. Failure was felt to be due to a mechanically imperfect stoma in three, to an incomplete vagotomy in one, to the dumping syndrome in one, and to severe psychoneurosis in one; in four instances, the reason was not clear. In 6 of these 10 patients, the presence of a marginal ulcer was proved roentgenographically, was seen at a secondary operation, or could be inferred from the clinical course.

COMMENT

Although gastric resection has proved of value in the treatment of duodenal ulcer, the continued search by surgeons for alternative procedures is evidence that it is not a perfect solution. The principal objections to gastric resection are two: 1. It is an intrinsically hazardous procedure, which in the hands of master surgeons still carries a mortality rate of 2% to 4%. The mortality in the hands of the average surgeon can only be conjectured, but it is certainly much higher. 2. Many patients who have had two-thirds or more of the stomach removed cannot be considered "normal" from a digestive standpoint. While the patients are free from ulcer symptoms and the complications of ulcer, the majority of careful investigators find that, after gastrectomy, a substantial proportion of patients fail to regain their normal weight and often suffer in some degree from "stomach consciousness," anemia, malnutrition, or the dump syndrome, or must follow a restricted diet. The fact that these discomforts usually are insignificant in comparison with the symptoms for which the patient had his operation may lead both surgeon and patient to treat them lightly. The surgeon performing a gastric resection for duodenal ulcer still faces a delicate problem: the less stomach he removes, the more likely is recurrence of ulceration; while the more stomach he removes, the more likely is the occurrence of other sequelae.



Summary of results of surgical treatment of duodenal ulcer in 147 patients.

The initial appeal of vagus resection was tremendous, since it appeared to answer both the objections to gastric resection, in offering a substantially lower mortality rate and in leaving intact the entire digestive tract. As so often occurs with new procedures, time was necessary to establish certain shortcomings. It is now clear that transthoracic vagotomy has at best a very limited usefulness, since it prevents an accurate operative diagnosis of gastroduodenal pathological changes and also results in a high incidence of persistent gastric retention. It has likewise become clear that vagus resection has no place in the surgical treatment of gastric ulcer (in which gastric resection is almost invariably indicated) or in the treatment of gastritis or gastric neuroses. It may also be regarded as established that, in the treatment of duodenal ulcer, a vagus resection should not be performed without an accompanying drainage operation. Yet, failures resulting from the practices noted above are still cited as evidence that vagotomy has no place in the treatment of duodenal ulcer. Some authors lump together gastric ulcer, duodenal ulcer, and marginal ulcer as if they were the same disease and may even confuse the issue further by failing to separate the procedures done with the vagotomy, such as gastroenterostomy, pyloroplasty, or gastric resection. When the data are broken down to cases of a specific lesion (i. e., duodenal ulcer) for which a specific operation was performed (i. e., vagotomy with gastroenterostomy) the number of failures often becomes too small to be of significance.

We feel that some of the surgeons currently condemning vagotomy with gastroenterostomy on the basis of personal experience may have used the operation in a selective way without realizing the consequences of such selection. For example, a surgeon who finds little or no evidence of an ulcer at operation is usually unwilling to perform a gastric resection but may decide to perform a vagotomy with gastroenterostomy rather than do nothing. Results in such borderline cases are almost always poor, since the symptoms are usually due to some other condition. If the surgeon habitually performs a gastric resection for a real pathological condition, and vagotomy for a questionable pathological condition, he is bound to be disappointed with his results from vagotomy.

Many experienced surgeons who regard gastric resection as the procedure of choice contented themselves in the prevagotomy days with performing a simple gastroenterostomy for duodenal ulcer in patients in whom old age, obesity, serious coexistent disease, or technical difficulties rendered gastrectomy unduly hazardous. Under similar circumstances some now add vagotomy to the gastroenterostomy. This is undoubtedly a sound and conservative surgical practice and should yield good clinical results, but it may produce misleading statistics and a deceptively low mortality rate for gastric resection. More studies of consecutive series of patients surgically treated for duodenal ulcers are needed for proper evaluation of the two procedures.

Finally, it is certain that many surgeons have been discouraged by a high incidence of persistent gastric retention following vagotomy with gastroenterostomy. We feel that certain technical details in the placement and execution of the gastroenterostomy have great bearing on this point, as emphasized by one of us (G. C.).[4] These details have received insufficient emphasis in the literature. We shall give this matter further attention in a subsequent publication. In our hands, the supplementary gastroenterostomy has proved superior to a pyloroplasty.

Bearing in mind the possibility that a longer period of observation may reveal flaws in the operation not now apparent, we believe that our experience of 90% satisfactory results justifies the policy of continuing to perform vagus resection with gastroenterostomy as the operation of choice for duodenal ulcer. We feel that the operation has no place in the treatment of gastric ulcer or in patients who have no demonstrable pathological condition at the time of surgery. We recognize that failures will occur and that some patients will require a subsequent gastric resection. It is possible that careful study of the failures will reveal some as yet unrecognized clinical features, enabling prediction of failure from vagus resection and permitting selection of the small group of patients in whom a gastric resection should be done as the primary procedure.

SUMMARY

The results in 147 patients treated for duodenal ulcer by subdiaphragmatic vagus resection with gastroenterostomy is reported after a follow-up of two to four years. Seven patients were not traced; thus the follow-up is 95% complete. In 90% of the patients, the operation has produced a satisfactory clinical result. In 10%, the results have been unsatisfactory, including failure in 6.8%. During the period studied, approximately 13.5% of patients treated for duodenal ulcer in the Cleveland Clinic Hospital underwent operation. In approximately half the patients included in this report, surgery was performed for one or more of the major complications of duodenal ulcer.

The operation is not advocated for gastric ulcer (for which gastric resection is the procedure of choice) nor for patients who do not show clear-cut evidence of ulcer at the time of operation. It should not be performed as an emergency procedure for active hemorrhage. In view of the good clinical results and a low operative mortality (less than 1%), further employment of the procedure seems warranted.

Diagnostic Significance of 17-Ketosteroids.—The urinary 17-ketosteroids may be determined simply and accurately in the laboratory. They reflect the secretory activity of the testes and the adrenal cortex. The values obtained appear to be of little diagnostic significance in testicular hypofunction, but may be of considerable assistance in ascertaining the state of the adrenal cortex. However, an abnormally low value for these steroids is of no diagnostic significance in itself, since there is a lowered 17-ketosteroid excretion in many nonspecific chronic diseases. In those conditions with an intact adrenal cortex, the administration of ACTH over a period of time will cause an elevation in these values.

In the adrenogenital syndrome this laboratory determination is of greatest diagnostic importance. The 17-ketosteroids will not only assist in making the diagnosis of adrenal virilism, but may be of help in determining the nature of the underlying adrenal pathology, whether it be hyperplasia, adenoma or carcinoma. If a neoplasm is present, surgical extirpation is indicated. If hyperplasia is present, the administration of cortisone appears to be the treatment of choice at the present time. The success or failure of therapy can be easily gauged by following the urinary 17-ketosteroid values.—Joseph W. Jailer, M.D., Diagnostic Significance of the 17-Ketosteroids, *The Medical Clinics of North America*, May, 1952.

COORDINATED MEDICAL PROGRAM FOR DOMICILIARY PATIENTS IN A VETERANS HOSPITAL

Thomas F. Barrett, M.D., Daniel B. MacCallum, M.D., Maxwell J. Binder, M.D.
and
Cleo B. Nelson, Los Angeles

The Veterans Administration is at present furnishing medical care to approximately 17,000 chronically ill veterans in 15 domiciliary units in the United States. The largest of these domiciliary units has a capacity of 3,074 veterans and comprises part of the Los Angeles Veterans Administration Center. A 1,400 bed general medical and surgical hospital and a 2,000 bed neuropsychiatric hospital complete the medical facilities of the center. Both hospitals function under the Veterans Administration Deans' Committee Program.

MEDICAL PROGRAM

During the past two years, a coordinated medical program has been established in the domiciliary unit under the supervision of the chief of professional services of the general medical and surgical hospital. The purpose of this program has been to improve the medical care given the 3,074 chronically ill, aging veterans residing in the domiciliary unit by (*a*) critically evaluating their medical, psychological, and sociologic problems, (*b*) returning as many as possible to a more useful and relatively more normal life in the outside community, (*c*) providing those remaining in the domiciliary unit with an integrated therapeutic regimen and medical follow-up, (*d*) training physicians in clinical geriatrics, and (*e*) providing opportunities for investigative studies of a well-controlled aging population.

The backbone of this program has been a general practitioner system, in which each of the eight 400-bed buildings operates as a modified hospital wing and is manned by a team consisting of a full-time physician, a part-time physician, a registered nurse, and a medical secretary. The ultimate responsibility for the patient's complete medical care rests with the full-time general practitioner and his part-time associate. The nurse's duties combine those of a public health nurse with those of an office nurse. Specialistic examinations are obtained from a domiciliary consultation service, called a diagnostic clinic. This consists of four full-time certified internists, aided by three full-time medical residents, and functions under the Deans' Committee Program. With the aid of medical and dental personnel from the nearby general medical and surgical hospital, the diagnostic clinic provides a consultation service covering all the medical and surgical specialties. The departments of physical medicine and social service have an indispensable role in the medical program.

A mental hygiene clinic has been established because of the high incidence of psychological problems among the domiciliary patients. It is staffed by two psychiatrists, two clinical psychologists, and five clinical psychology trainees, with one psychiatric social worker. This clinic has as its attending staff the chief of professional services of the adjacent neuropsychiatric hospital and his clinical psychologist. Consultation service is being arranged with the staff of the nearby University of California at Los Angeles medical school.

When hospitalization is necessary, continuance of the doctor-patient relationship essential to the general practitioner system of medicine is made possible through the facilities of a 30 bed ward set up for this purpose. The general practitioner retains responsibility for his own patients. Consultation is obtained, when needed, from the domiciliary consultation service.

A comprehensive screening procedure designed to aid in the rehabilitation of all new domiciliary members has been functioning since April, 1951. The veteran, having been found eligible for admission to the domiciliary unit, is thoroughly evaluated medically by the domiciliary consultation service. This evaluation includes the taking of a complete history and a thorough physical examination, with the use of any indicated laboratory procedures. A similarly thorough psychological, vocational, educational, and social evaluation of the veteran then follows. The veteran's composite picture is completed with an evaluation by the department of physical medicine. The information obtained by this screening procedure forms the basis of a rehabilitation program individually tailored to the needs of each veteran. The rehabilitated veteran is returned to a more useful life either in the outside community or in the domiciliary unit.

1950 DOMICILIARY POPULATION

The mean age of the 3,864 domiciliary patients examined at this center in 1950 was 61 years. Of the total group, 53% were in the age group 55 to 64, while only 4% were under 45, and 9% were 75 or over (*fig. 1*). Analysis of morbidity among the entire group revealed that diseases of the circulatory system were far commoner than any other disease entity (fig. 2). Arterial disease, hypertension, and arteriosclerotic heart disease were the conditions observed in most of the patients in this category. The next commonest group was diseases of the nervous system and sense organs, closely followed by diseases of the musculoskeletal system and the respiratory system. Syphilis occurred in 500 patients; in 248 of these, the central nervous system was affected, and in 51 the

Reviewed by the Veterans Administration and published with the approval of the Chief Medical Director. The statements and conclusions of the authors are the result of their own study and do not necessarily reflect the opinion or policy of the Veterans Administration.

Chief, Professional Services, Medical Service, Veterans Administration Center, and Clinical Professor of Medicine, Department of Medicine, School of Medicine, University of California at Los Angeles (Dr. Barrett); Assistant Chief, Professional Services, Medical Service, Veterans Administration Center, and Visiting Professor of Anatomy, Department of Anatomy, University of Southern California School of Medicine (Dr. MacCallum); Chief, Diagnostic Clinic Medical Service, Veterans Administration Center, and Clinical Instructor in Medicine, Department of Medicine, School of Medicine, University of California at Los Angeles (Dr. Binder); and Medical Record Librarian, Medical Service, Veterans Administration Center (Mrs. Nelson).

cardiovascular system was affected. Malignant neoplasms were found in 200 patients and benign neoplasms in 65. Diabetes mellitus occurred in 172 patients.

In patients under age 45, diseases of the nervous system and psychogenic disorders were the most prevalent, both occurring in almost 50% of the patients in this group. In those over 45, diseases of the circulatory system were the leading causes of disability, occurring in about 75% of the patients and assuming increasing importance with increasing age. Multiple cardiovascular diseases were most prevalent in the older age groups. At all ages diseases of the nervous and musculoskeletal systems played a prominent role. Diseases of the digestive and respiratory systems were present in 25% of the patients over age 45 and seldom occurred in patients below that age. The incidence rate of malignant disease increased from 1 per 100 patients under age 45 to 9 per 100 patients over age 65.

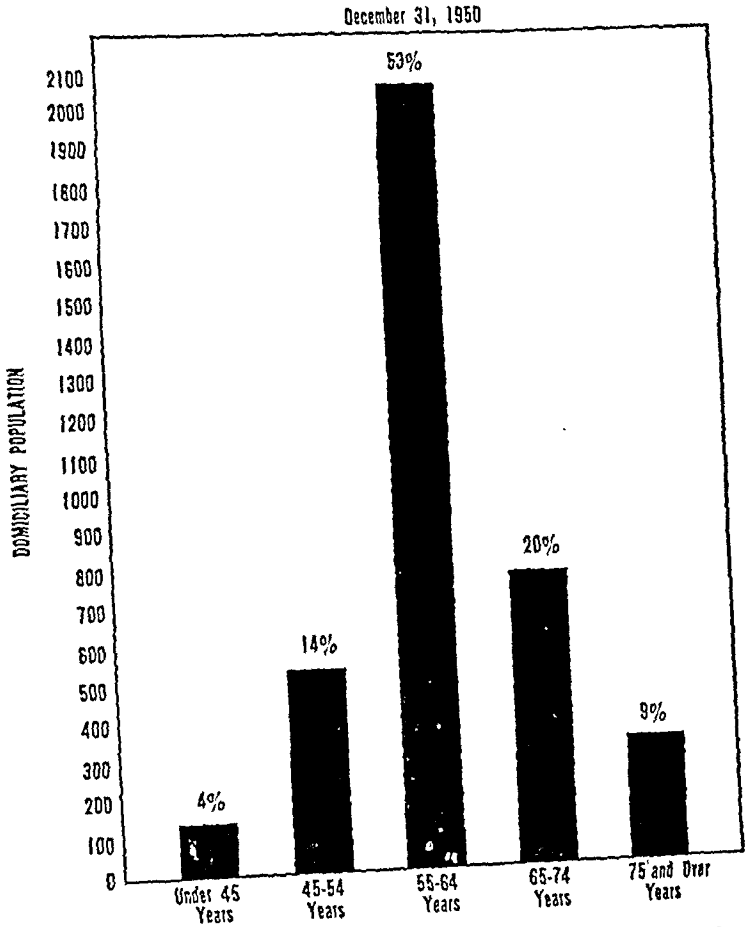

Fig. 1.—Distribution of 1950 domiciliary population by age groups.

Two hundred sixteen deaths occurred in the domiciliary unit in 1950. Diseases of the circulatory system, the leading cause of illness in patients over age 45, was also the leading cause of death, being responsible for 57% of the deaths in this age group. Malignant disease, while not a leading cause of illness, was the second leading cause of death in patients over 45, being responsible for 16% of the deaths in this age group. Two deaths occurred in patients under age 45, both due to urologic disease.

RESULTS OF THE PROGRAM

In 1948, admissions of domiciliary patients to the general medical and surgical hospital for surgical treatment averaged 87 patients for each three month period. The corresponding figure for patients admitted to the hospital for medical care was 213. Shortly after the medical program was started in July, 1949, a sharp and significant rise occurred in the number of patients admitted for surgical treatment. In most cases these were short term admissions for elective surgical procedures. The peak occurred early in 1950, at which time 52% more domiciliary patients were receiving surgical treatment than in 1948. We feel that this was due to the careful medical and surgical evaluation the patients received and to the fact that chronological age alone was not considered a deterrent for elective surgical treatment. No significant effect on the number of patients admitted for medical care was apparent until one year after the program had been in operation. Since then, there has been a steady increase in such admissions, and by early 1951, a decrease of 60% had occurred (fig. 3).

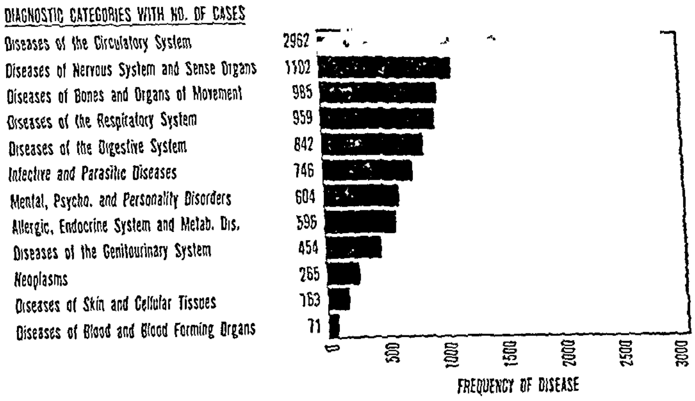

Fig. 2.—Incidence of selected diseases among the 3,864 domiciliary members in 1950. (Includes all disease conditions diagnosed and recorded as first, second, and third diagnoses.)

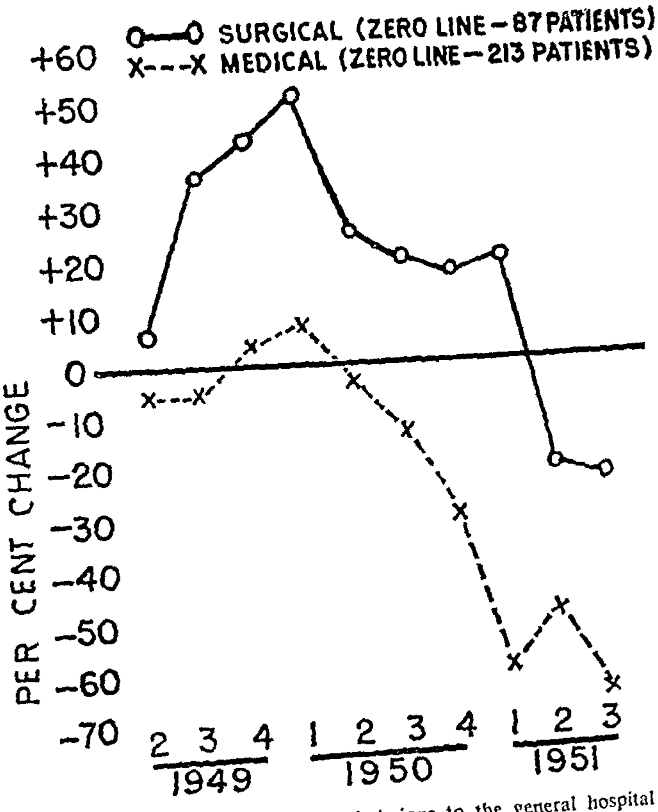

Fig. 3.—Percentage change in admissions to the general hospital since inception of the new medical program.

The rehabilitation program has been in effect too short a time for proper evaluation of the available data; however, only 10 (8%) of the first group of 121 newly admitted patients were considered unsuitable for rehabilitation. Twenty-eight patients (23%) of this group have been rehabilitated to a more useful life in the outside community or in the domiciliary. The remainder have not yet completed the prescribed therapeutic regimen.

COMMENT

The problem of chronic illness in an aging population has become a major one for the Veterans Administration. As the country's veteran population becomes older, it is expected that this problem will increase in importance. The high incidence of disabling organic disease found in this study illustrates the need for a coordinated medical program. It is recognized that medical care in the older age groups must include not only therapy for the patient's disease but proper attention to his psychological, sociologic, and economic problems. During this study, it became evident that not only must the influence of psychological and functional states on organic disease be evaluated, but similar stress must be placed on the influence of organic states on the patient's mental outlook. Both are influenced by the patient's home environment. The effect on the patient of a protected environment, such as is available in the domiciliary, needs further clarification.

The practice of detection medicine by periodic physical examination of the geriatric patient has resulted in earlier diagnosis and treatment of such life-threatening diseases as cancer and tuberculosis. The increase in the practice of surgical correction of partially disabling abnormalities has had similarly favorable results. We believe this program has resulted in improvement in the physical well-being and mental outlook of the patients. This is in part demonstrated by the decrease in medical admissions to the general medical and surgical hospital (fig. 3), with resultant increase in the availability of the hospital's facilities. A large contribution has been made by a program of occupational therapy, which is designed to provide a more useful life for those patients remaining in the domiciliary.

The life expectancy of the veterans analyzed in this study was estimated, using the experience of the white male population in the United States in comparable age groups[1] (see table). Based on the average 1950 per diem rate in all Veterans Administration domiciliary units, it is estimated that an expenditure of at least 55 million dollars for food, clothing, and shelter would be necessary for the future maintenance of these veterans if they spent the rest of their lives in the domiciliary. If a percentage of them can be rehabilitated to a more useful life in the outside community, much of this cost could be defrayed and existing facilities utilized to care for the increasing number of veterans seeking admission to the domiciliary.

Life Expectation in 1950 of Domiciliary Patients, According to Age Groups, and Prospective Cost of Their Domiciliary Care Until Death

Age Group	No. of Patients	Total Years of Life Expectation	Aggregate No. Days Future Care Required	Total Estimated Cost (Rate $3.04/Day*)
Under 45	145	4,438.3	1,621,089	$ 4,928,110.56
45 to 54........	516	9,575.9	3,497,597	10,632,694.88
55 to 64........	1,972	27,314.2	9,976,512	30,328,596.48
65 to 74........	708	6,505.8	2,376,243	7,223,778.72
75 and over...	397	1,619.5	602,068	1,830,286.72

* Average 1950 per diem rate in all Veterans Administration domiciliary units.

SUMMARY

1. A coordinated medical program has been instituted in the Los Angeles Veterans Administration Center domiciliary unit, which is designed to meet the problem of chronic illness in an aging veteran population.
2. Better total evaluation and care of the domiciliary patient has been made possible.
3. This program has resulted in improvement in the health, morale, and usefulness of these geriatric patients.

BRAIN FEVER

Louis Casamajor, M.D., New York

In the early years of the 19th century there began to appear in European medical journals—especially the French—descriptions of a disease variously known as brain fever, hydrocephalic fever, and, rarely, encephalitis.[1] At times the name of Pinel is attached to brain fever, and it may be that he originally described it. In any event he is credited with having differentiated it from meningitis. By the middle of the century no further medical articles appeared, although novelists continued to utilize the disease as dramatic incident until well along toward the end of the century. Early American textbooks of neurology contained no reference to the disease.

This disease occurred apparently almost entirely in children. It is difficult to get a clear idea of the clinical picture, for more than one condition was included in this terminology. Some cases were fatal, and the necropsies usually showed meningitis, most likely tubercular. Some patients recovered completely and must have had an entirely different disease. The symptoms recorded are entirely subjective and are those recognized today as indicative of cerebral involvement. The onset was usually sudden, but some were step-like. Often the first symptom was a convulsion; then were added headache, vomiting, coma or delirium, strabismus, aphonia, dyspnea, and in-

L.: Considérations pratiques sur la nature et le traitement de la fièvre cérébrale ou encéphalo-méningite, These de Paris, 1854, vol. 13.

termittent pulse. After a few days to a couple of weeks, the disease subsided and the patients recovered.

Although fever is mentioned in all the reports, there is no record of any temperatures, for temperatures in illness were not taken until after the invention of the modern clinical thermometer, in 1868.[2] No objective neurological signs appear in the reports, because the neurological examination as we know it today did not begin to develop until after Erb [3] described the changes in the tendon reflexes in spinal cord disease and Westphal [4] the loss of knee jerks in tabes dorsalis, both in 1875.

The treatment in these cases of brain fever was that of the times. Bleeding was freely used. The patients were given wine and brandy in different doses. Fantastic enemas consisting of wine, absinthe, asafedita and similar agents were given, which the colons promptly expelled. Some authors, notably Houdaille,[1b] expressed the belief that quinine was specific for the disease. Liégard [1f] recommended antimony inunctions to the scalp till pustules formed. Even with these treatments, apparently most of the patients recovered.

After about 1850 the disease disappeared from the literature. This was probably similar to the way in which the "encephalitis lethargica" of von Economo has disappeared from medical practice. During the 1920's and early 1930's epidemic lethargic encephalitis, with its acute phase and the long chronic stage of parkinsonism, was a very prevalent disease throughout the civilized world. The reports of the Matheson Commission abstract an enormous literature on the subject; yet today one no longer sees cases of the acute disease. One still sees some patients in the chronic stage, but the acute disease is no longer a problem. In a somewhat similar manner brain fever disappeared from the medical literature 100 years ago, but it has not disappeared from medical practice. Undoubtedly the condition does exist today.

REPORT OF CASES

CASE 1.—A. M. was 11 years of age when she entered the Neurological Institute, on Oct. 5, 1935. She was the fifth of eight children, all of whom were normal. Her development had been normal; she was considered to be a friendly, healthy girl whose interests were normal, and she was getting along well in school.

About a month previously her mother noticed a change in her. She "lost interest in things and moped around the house." She was sent to visit an aunt, and there she refused to play with other children or to leave the house. In the week she was away from her home nocturnal enuresis occurred on four occasions, which was the first time that had happened since she was 18 months of age.

On her return home she seemed to be "a different child." She frequently became angry with other children and "acted babyish." She did not want to go to school or leave the house for any other reason. At times, however, she would be very active, helping her mother with the housework and caring for the younger children.

On the evening of Sept. 28 she had her first seizure, involving the right side of her face. She was unable to talk but was conscious and responded to questions with head nodding. After being put to bed she cried all night. On the following morning she appeared to be normal, went to church, and played till late in the afternoon, when she again became irritable.

From this time on she continued having two or three attacks of right facial twitching, without loss of consciousness, with increasing frequency until on the day of admission they were recurring every few minutes. When we first saw her she was having seizures frequently. Most of them were only in the right side of the face, but some spread to involve the right arm and leg. The neurological examination revealed nothing essentially abnormal, but there was a right facial weakness of the central type and the left optic disk appeared blurred. All the deep and superficial reflexes were active and equal on both sides. Between seizures there was no difference in the functions of either arm or leg. The blood cell count, blood chemical studies, and serologic studies disclosed no abnormalities. Examination of the spinal fluid showed five cells and 22 mg. of protein per 100 cc. Later lumbar punctures showed no higher cell count or protein content.

As the child remained on the ward her condition became worse. Seizures on the right side and sometimes of the whole body occurred as often as every minute. Sometimes the seizures were of a psychomotor sort, in which she would shout and scream, beat her head against the wall, tear her clothes, and throw things around the room.

The neurological findings continued as above. On Oct. 10 an ophthalmologist reported increased congestion of nerve heads, with hazier margins. The large and small veins show increased engorgement. On Oct. 15 a pneumoencephalogram showed no significant abnormality, although the ventricles were poorly filled. The right-sided convulsions were still practically continual. On Oct. 29 the right side of the face and the right arm were paralyzed. The child understood speech but was unable to talk. Occasionally her temperature rose to 102 F.

On Oct. 30 improvement was obvious. Her seizures became less severe and less frequent. She could talk and move her right arm, although it was somewhat unsteady and ataxic. The last seizure, a completely right-sided one, occurred on Nov. 5. The right arm after this was ataxic for a few days and showed some involuntary movements. She could not yet talk plainly, and she showed some confusion at times. The results of neurological examination on Nov. 11 were reported as absolutely normal.

When the patient was discharged from the hospital, on Nov. 28, 1935, she seemed normal in every respect. Neurological observations remained normal. There have been no further seizures, and she has received no anticonvulsive medication. She returned to school and, at 14 years of age, was graduated from grade school as fourth in her class, with an average of 92%. In high school she was on the honor roll and was graduated at 18 years. Since then she has held a clerical job. In January, 1946, she married; when last seen, on July 26, 1951, at the age of 27, she appeared to be a healthy, happy, and intelligent woman.

Comment.—This can be taken as a typical case of brain fever. Neurological symptoms and signs are indicative of the location rather than the nature of the brain disease. The spread of the disease is also not always the same. In some cases the disease seems to be restricted to the cerebral cortex and in others to the base and stem of the brain.

CASE 2.—B. W. was 6½ years old when she was admitted to the Neurological Institute, on April 4, 1942. She was the second of two children, a bright girl, and doing well in school. She spoke both English and Polish and acted as interpreter fo her parents. She was well until the middle of March, 1942, whe she began having irregular temperature increases, called "septic." She was kept in bed with conservative treatment. On Marc 30 she complained that everything seemed dim, and in two hou she was completely blind. She was taken to a local hospital an it was reported that she had bilateral papilledema, leukocytos (48,000 with 93% polymorphonuclear cells), increased sedime tation rate, and normal spinal fluid.

On admission to the Neurological Institute she appeared be completely blind and could not stand alone. Her pupils d not react to light; the optic disks were definitely blurred, b the vessels appeared normal. When she attempted to stand alo she fell backward, but none of the other neurological signs were present. The choked disks were considered to be due to retrobulbar neuritis.

[3] Erb, W. H.: Ueber Sehnenreflexe bei Gesunden und bei Rueckenmarkskranken, Arch. f. Psychiat. 5: 792, 1875.

[4] Westphal, C. F.: Ueber einige Bewegungs Erscheinungen an Gelaemten Gliedern, Arch. f. Psychiat. 5: 803, 1875.

For days she had a low-grade fever, with temperatures between 99 and 100 F. The leukocyte count was 28,000, with 80% polymorphonuclear cells. The count rose to 31,000 and then gradually diminished, but it remained between 13,000 and 20,000 during the months of April and May. By June 8, when she was well on the road to recovery, her leukocyte count was 8,700, with 69% polymorphonuclear cells.

Examination of the spinal fluid on admission showed 30 cells (48% polymorphonuclear cells and 52% lymphocytes) and 43 mg. of protein per 100 cc. This rose as high as 50 mg. per 100 cc. and then decreased, together with the cell count, which was down to 8 on April 28. Dr. Lester Webster, who had organized a laboratory for virus studies in the Rockefeller Institute, examined the blood and spinal fluid of this child at the height of her illness. He found no complement fixation against antigen of any of the known encephalitis viruses, and the spinal fluid proved negative when tested in mice.

At first the child was apathetic and content to lie quietly in bed, but she always cooperated well in the examinations. The blindness persisted, and the eyegrounds remained unchanged. At times she showed a right facial weakness and inability to stand alone, which was considered cerebellar in origin. No real change occurred until April 25, three weeks after admission. On that day the right facial palsy became more marked, her speech was nasal, and she had difficulty in swallowing. These symptoms disappeared after about 15 minutes but recurred together with irregular respiration a number of times during the day.

On April 26, her breathing became purely abdominal and jerky and she was in coma. When this episode passed, her speech was thick and nasal and her deep reflexes were hyperactive but equal. Later a questionable Babinski toe sign was noted on the right. That evening her respiration ceased and she was comatose, with contracted pupils. When placed in a respirator she responded immediately; she remained there for five days.

When the patient came out of the respirator, the picture was one of complete cerebellar asynergia but her vision had improved so that she could count fingers at 5 ft. and recognize colors. Not only was she unable to stand erect but she could not even crawl. When she tried to progress on hands and knees, her hips tended to fall over to the left. The right facial palsy persisted.

This was the first case in which electroencephalographic records were available. Three days after admission the electroencephalogram showed diffuse high voltage one to two per second waves in all leads, most consistently in the occipital areas. Bipolar recording showed widespread phase reversals in all areas. These findings did not change all the time she was hospitalized.

By early June the patient had fully recovered and was considered normal but possibly a little overactive. She was discharged on June 18 and since then has led a normal life. She never had any convulsions. Her progress in school was what one would expect of a child of her background. When last seen in the clinic, in September, 1951, at 15 years of age, the girl appeared normal and the results of the neurological examination were entirely negative.

Comment.—This child had all the signs of severe cerebral involvement except convulsions. This could have been because mainly the base of the brain and the hind brain were involved. At the start the spinal fluid showed signs of meningeal involvement, so that the condition could be called meningoencephalitis. Meningeal signs have been rare in this series of cases, but in the next case they were more prominent.

Case 3.—G. S. was nearly 7 years of age when she was admitted to the Neurological Institute, having been transferred from Babies Hospital, on Feb. 18, 1949. She was an attractive little girl who had always been considered bright. She had always been well until in July, 1948, at the age of 6½ years, when she began to complain occasionally of brief frontal headaches and easy fatigability. This condition continued intermittently for the next five months and did not seem to be getting worse.

On Christmas day, 1948, she suddenly stiffened and became confused. She was unable to walk downstairs and had to be carried. Later in the day she completely recoverd her ability to walk. She remained well until the night of Jan. 9, 1949, when she slept poorly and had a headache. In the morning she had a temperature of 102 F and was drowsy. She continued to be ill, and, as she seemed to be getting worse, she was removed to the Physicians Hospital, Jackson Heights, N. Y.

A neurological examination on Feb. 2 was reported as showing neck rigidity, Kernig's sign on the left side, severe headache, right central facial weakness, hazy optic disks, general hyperreflexes, and a positive Babinski sign on the right. Spinal fluid examination on Jan. 16 showed 53 cells (85% lymphocytes) and 41 mg. of protein per 100 cc. On Jan. 25 the cells had increased to 110, with 62% polymorphonuclear cells, and the protein had increased to 54 mg. per 100 cc.

On Feb. 5 she was admitted to Babies Hospital, with stiffness of the neck, a positive Brudzinski sign, bilateral transient ankle and patellar clonus, blurred optic disks and occasional right facial weakness.

On Feb. 18, when she was transferred to the Neurological Institute, she could support her weight on her feet, but her balance was very poor. The pupils were normal, and the optic disks were blurred, with small arteries and veins. There was slight right facial weakness. Arm reflexes were equal, but leg reflexes were greater on the right. There was no Babinski sign. Spinal fluid examination showed 16 cells, all lymphocytes, and 39 mg. of protein per 100 cc., which later increased to 46 mg. The blood leukocyte count was 5,400 (68 polymorphonuclear cells and 24 lymphocytes). Temperature ranged from 99 to 101.8 F. An electroencephalogram on Feb. 10 was grossly abnormal, with high voltage slow activity, two to four waves per second. This activity appeared focal in the two frontal areas and a large area of the left temporal and occipital. A pneumoencephalogram on Feb. 25 was reported as essentially negative.

The patient's condition improved steadily from the time of admission. By March 2 her gait was practically normal, and there was no facial weakness. All reflexes were active and equal, and optic disks were normal. On March 12 the electroencephalogram still showed partly high voltage three to four per second waves in both parietal and occipital areas but no longer in frontal areas.

On March 13 the patient was discharged from the hospital; she was followed in the clinic. She returned to school, where her progress was normal. The last electroencephalogram, made on Feb. 2, 1950, showed no focal signs, and only on hyperventilation were occasional high voltage bursts of two to three per second waves seen. She remained well, with no abnormal neurological findings. She was last seen on Oct. 3, 1951.

Comment.—In the last two cases the condition was rather severe, with meningeal as well as cerebral signs. In not all the cases is the disease so severe; in some it is milder and of much shorter duration. This is especially true in some of the cases in which convulsions occur.

Case 4.—M. S. was nearly 8 years of age when she was admitted to the Neurological Institute, on June 16, 1950. She was an alert girl, with an I.Q. of 94. On June 10, 1950, she was running down a hill with her 6-year-old brother when they collided and she struck the left side of her head against her brother's. There were no immediate symptoms from the blow, which apparently was a minor one. That night she awoke several times complaining of left-sided headache. The following morning she vomited once and ate very little, but in the afternoon she went outdoors and played normally. She was heard to cry intermittently during the following night. On June 12 and 13 she vomited several times and complained of left-sided headache.

On June 14 she complained of dizziness and did not seem to be able to walk. When she was taken to a hospital for skull x-ray that morning, her father had to carry her. The x-ray was reported as negative. On June 15 she was much improved but still complained of left-sided headache. There was some stiffness of the neck, and her left eyelid drooped.

On the morning of June 16 she awakened early and shortly thereafter was found unconscious in bed, with her head and eyes turned to the right and the eyelids open. She was then taken to St. Vincents Hospital, Staten Island, where she had several generalized seizures, recovering consciousness in the intervals. That day she was transferred to the Neurological Institute.

On admission she was drowsy, with considerable weakness of the right arm and leg. All deep tendon reflexes were sluggish but equal on the two sides. The leukocyte count was 5,200, with 84% polymorphonuclear cells; her temperature was 99.6 F. Spinal fluid examination showed 7 cells, all lymphocytes, and total protein of 33 mg. per 100 cc. The electroencephalogram showed grossly abnormal activity all over the left hemisphere, while the right was fairly normal. The frequency wave range was one to three per second, of high amplitude with phase reversals all over the left side.

The patient remained hospitalized for 12 days. Her temperature never rose above 100.4 F. She never had another seizure of any sort. On the second morning she was alert and free from headache, but there still was some weakness in the right arm and leg, which disappeared the following day. On June 23 a second electroencephalogram was made. The first part of the record showed a striking improvement, in that now only moderate amounts of low to medium voltage of five per second waves were seen over the left temporal and occipital areas. On hyperventilation some bilateral partly high voltage three to four waves per second were seen.

The patient had no further seizures and received no anticonvulsive medication. She returned to school in the fall and made good progress. An electroencephalogram made on May 5, 1951, showed normal activity throughout but a bit more irregular activity in the left temporal and occipital areas. The neurological observations remained normal. The patient was last seen on Dec. 19, 1951.

COMMENT

These patients presented certain features in common. They were all children. Each had a severe disease with signs of cerebral involvement. The course of the disease was more or less acute and terminated rather rapidly in complete recovery.

It was considered that the conditions in these patients were in the group of the encephalitides. This is clinically a very poorly defined group. Specific viruses have been recognized for five encephalitides. In the only case in this series in which virus studies were made, no known viruses were found. The same was true of other similar cases in this hospital. It is not necessary for one to isolate and recognize any virus or other causative agent in order to make a diagnosis of encephalitis. One must remember that the primary causative factor of epidemic encephalitis of von Economo was never isolated or recognized, in spite of the fact that this was a definite and easily recognizable disease and a great deal of intensive work was done on it. All evidence showed that the cause was a filtrable factor, but nothing more definite was ever discovered.

Encephalitis can be regarded as an acute disease in which the symptoms are those of brain involvement. Frequently the blood and temperature show signs of an inflammatory nature. Sometimes this inflammation appears in the meninges and shows in the spinal fluid. Different parts of the brain may be principally involved, with a resulting difference in clinical pictures. The onset in most of my cases extended over a considerable time, with episodes of abnormal behavior alternating with normality before the real onset of the permanent condition appeared. In case 4, however, the onset was rather sudden, following a slight or only moderately severe injury. In such a case the clinician may justly think of a possible subdural hematoma. The course of the disease, however, excludes this possibility. It may well be that, when a brain is beginning to be affected by encephalitis, even the slightest sort of an injury may precipitate the onset and determine the location of the principal lesion, as in case 4.

The diagnosis is made on the basis of the general and neurological signs. By far the most valuable of these are the electroencephalographic changes. In every case on the children's service the electroencephalogram shows most striking signs—a cerebral dysrhythmia with large irregular waves that may be focal. When the disease is of short duration, the dysrhythmia recedes rapidly (case 4). In long-continued cases this dysrhythmia may be present for many months.

Possibly it is an error to consider the condition in the cases reported here to be the same as that the earlier clinicians called brain fever, but they have many features in common. Brain fever does not seem to be such a poor term to apply to them to indicate a special form of encephalitis.

CONCLUSIONS

Clinicians early in the 19th century reported cases of severe disease of an encephalitic sort under the name of brain fever. Many of their patients, in spite of the severity of the disease, recovered. The condition exists today. In this article four cases of a severe encephalitic disease of the present time and with complete recovery are reported.

Usually the onset is irregular and may extend over a number of months. When slight or moderate head trauma has been sustained, the onset may be rather sudden. The symptoms and signs are those of considerable brain involvement, including convulsions, comas, paralyses, cerebellar asynergy, and a sort of bulbar palsy. In the diagnosis the electroencephalogram is of the greatest value.

168th St. and Ft. Washington Ave.

Neurologic Medicine.—Neurology sprang from internal medicine. Its earlier exponents were internists with a special interest in diseases of the nervous system, many of whom, such as Gowers, Charcot, Strümpell and Pierre Marie, have made notable contributions to subjects other than neurology. . . . The rise of neurosurgery as an independent specialty, the success of syphilology in its own field and the mounting aggressiveness of psychiatry soon encroached on what had been considered the neurologist's field, and by the 1930's there were many who predicted the extinction of the genus neurologist. Some professed neurology as an appendage to neurosurgery or psychiatry—and indeed a few professed all three. Many neurologists and neurologic departments became absorbed by departments of neurosurgery or else adopted protective coloring in the form of the title "neuropsychiatrist" and still exist in unhappy dependence on these borderlands. . . . Neurology, to mean anything at all, must mean neurologic medicine and as such must comprise all diseases that in any way affect the nervous system. Since many more diseases may affect the nervous system secondarily than those that attack it exclusively and since more and more of the latter can be shown to be special aspects of the former, neurologic medicine is quite inseparable from internal medicine. The neurologist must be first an internist. His inspiration is in the general medical wards; his techniques are those of internal medicine.—D. E. Denny-Brown, M.D., The Changing Pattern of Neurologic Medicine, *New England Journal of Medicine,* May 29, 1952.

IMPROVED ABRASIVE BALLOON FOR DIAGNOSIS OF GASTRIC CANCER

Frederick G. Panico, M.D., Baltimore

The abrasive gastric balloon[1] technique has assumed a place in the diagnosis of gastric cancer because it secures many gastric cells in a good state of preservation. Because of the abrasive balloon test, lesions of the stomach are no longer inaccessible, and the diagnosis of these lesions becomes not only interesting but rapid and reliable. The purpose of this paper is to advance the procedure for general availability.

APPARATUS

The apparatus needed for the abrasive gastric balloon test is easily assembled. The balloon is a thin latex rubber condom 20 cm. long. The surface of the improved balloon is made abrasive by attaching with rubber cement 75 to 100 small, round, 3 mm. fragments of foamed latex rubber. The fragments of foamed latex rubber are arranged in a regular pattern 1 cm. apart. This balloon system has some advantages over that originally reported in that it is made entirely of latex rubber and has a softer consistency, it is a larger balloon with an increased surface area capable of inflating and filling almost the entire stomach cavity, it has the capacity to yield satisfactory cellular material from the stomach and esophagus, it presents a better psychological appearance, and it has a construction more suitable for manufacture.

The improved abrasive balloon may be applied to the double lumen apparatus previously described if aspiration studies are going to be conducted coincident with the cytological studies. Since controlled comparative studies reveal that diagnostic specimens are obtained from the balloon surface, the abrasive balloon may be applied to a single lumen apparatus without an aspirator (fig. 1). This apparatus consists of a no. 18 French single lumen tube 90 cm. long, to which a one way metal adapter is fitted at either end. To the proximal metal adapter is connected a piece of rubber tubing, 10 cm. long, attached to a rubber inflator bulb with an air control valve. To the distal metal adapter is connected a varying 10 to 20 cm. long piece of no. 18 French single lumen tubing perforated in the center. The distal lumen is closed off with a silver plated blind metal tip. In this way, the distal portion of the apparatus is prepared to accommodate an inflatable abrasive gastric balloon. The abrasive balloon may be used in its full length of 20 cm. or may be shortened to 10 cm. as desired. The abrasive balloon fitted on the apparatus is sealed by silk ties distally around the silver plated blind metal tip and proximally around the one way metal adapter. By means of the rubber bulb air may be introduced through the tube and its perforation to inflate the balloon. In the event that the no. 18 French single lumen tube is not rigid enough for handling, more rigidity may be obtained by employing a thicker no. 20 French single lumen tube or by incorporating a cylindrical coiled wire within the lumen of the tubing. The apparatus finally assembled has markings at 45, 55, 65, and 75 cm. from the distal tip for judging its placement in the stomach.

PROCEDURE

Preparation of the patient revolves around the problem of emptying the stomach as much as possible prior to the introduction of the abrasive gastric balloon, so that minimal displacement of the balloon from the stomach mucosal surface is assured. A liquid diet the day prior to examination followed by an 8 hour fasting period prior to the insertion of the abrasive balloon has given good results. A preliminary gastric analysis to determine the index of gastric acidity will usually give the observer an idea of the retentive property of the stomach. In cases of gastric retention, extra preparation may be accomplished by gastric aspiration, longer periods of liquid ingestion, and additional fasting.

Materials needed for conducting a 15 minute diagnostic procedure are easily procured. They consist of an ethyl aminobenzoate lozenge, an abrasive gastric balloon apparatus, a cylindrical beaker filled with 100 cc. of isotonic sodium chloride solution, two 50 cc. centrifuge tubes, three glass slides, and a container with equal parts of ether and 95% ethyl alcohol fixative.

The prepared patient is seated in an upright position and given an ethyl aminobenzoate lozenge to dissolve under his tongue, and a towel is placed under his chin. The abrasive gastric balloon completely deflated is moistened. As it is placed into the mouth, the patient is asked

From the Department of Surgery, University of Maryland School of Medicine and the Baltimore City Hospitals.

[1] Panico, F. G.; Papanicolaou, G. N., and Cooper, W. A.: Abrasive Balloon for Exfoliation of Gastric Cancer Cells, J. A. M. A. 143: 1308-1311 (Aug. 12) 1950.

to swallow the balloon. In many instances, the patient may direct the swallowing of the balloon without the aid of the examiner. Fluid is administered orally only as necessary. All saliva, postnasal discharge, and pulmonary excretions are discarded to prevent swallowing of unnecessary cellular debris. As the balloon passes through the constrictor muscles of the hypopharynx, there is at times an accompanying cough reflex. This produces no difficulty, and the patient is encouraged to keep swallowing. Once the balloon is in the esophagus, it descends by itself with relative ease, and the patient experiences no discomfort. When the balloon reaches the cardia at a distance of about 55 cm., the direction of passage of the balloon tip toward the pylorus may be facilitated by placing the patient in a right lateral recumbent position. With the patient completely relaxed, the balloon descends to about 75 cm. into the region of the pylorus (fig. 2). With this method, there should be no coiling of the nonrigid tube, and the abrasive gastric balloon is positioned without the aid of fluoroscopy. If the tube is made semirigid, the patient need not be placed in a recumbent position but may be examined throughout the procedure in an upright position. The balloon is inflated slowly by injecting approximately 150 to 250 cc. of air. Ordinarily the free balloon averages 6 cm. in diameter; however, as expansion of the balloon occurs in the stomach, the proximal end of the balloon meets the least resistance and inflates first. This tends to pull the balloon retrograde through the prepyloric antrum into the body of the stomach (fig. 3). As can be seen fluoroscopically, reactive peristalsis may help the balloon in its proximal shift. Hyperperistalsis can be seen in the regions of the stomach not in direct contact with the balloon surface. As the balloon passes through the body of the stomach, peristaltic waves may cause a constricting effect around the balloon. Slowly the balloon is withdrawn into the cardiac region of the stomach where it is checked at the cardia. This is occasionally accompanied by a vomiting reflex (fig. 4). At this point, the balloon is deflated and returned to the pylorus, where it is blown up again. This is repeated three times, an interval of one minute being arbitrarily used for transferring the balloon from the pylorus to the cardia. At the end of three minutes the balloon is withdrawn to the cardia and allowed to collapse completely before being retrieved. The abrasive balloon carrying the specimen of

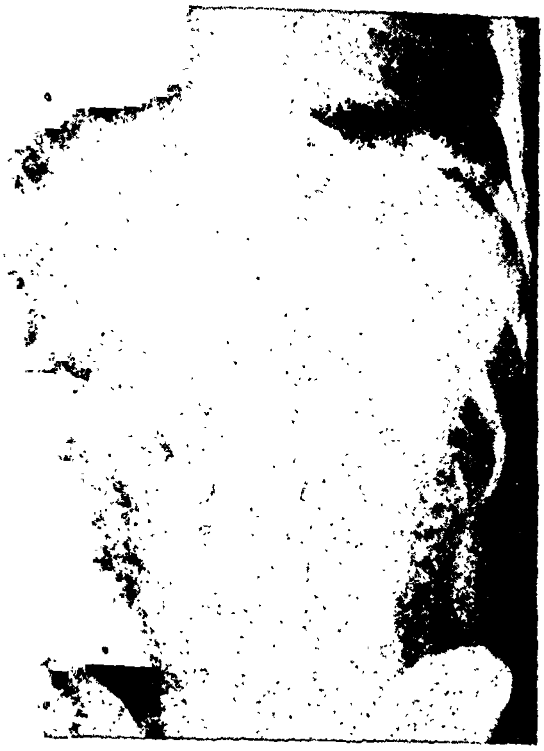

Fig. 2.—Roentgenogram showing uninflated abrasive gastric balloon inserted to the pylorus.

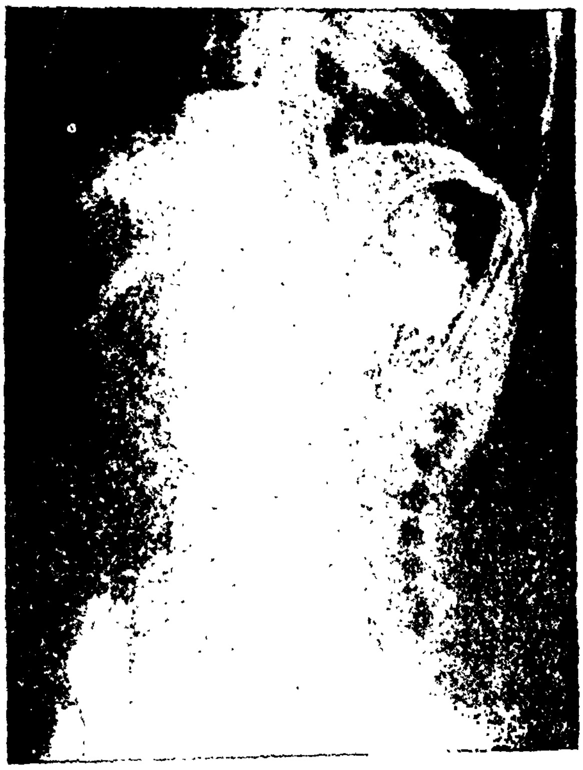

Fig. 3.—Roentgenogram showing inflating abrasive gastric balloon traveling retrograde through the prepyloric antrum and body of the stomach, stimulating reactive peristalsis.

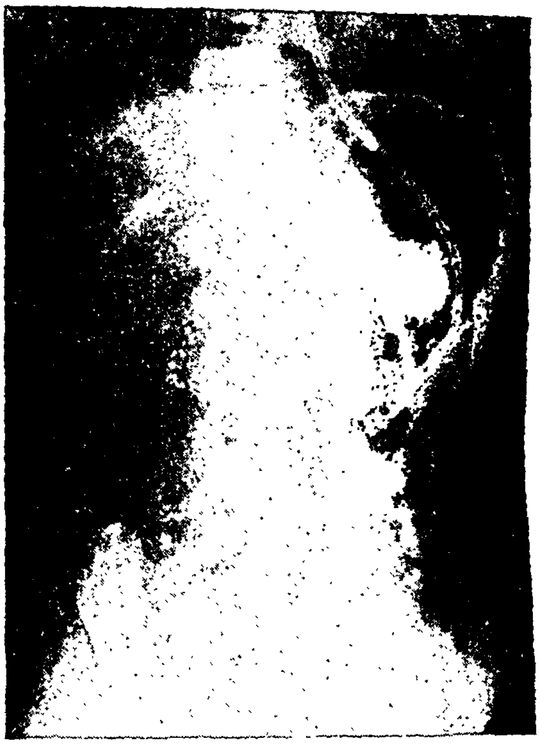

Fig. 4.—Roentgenogram showing inflated abrasive gastric balloon distending the cardiac and fundic regions of the stomach prior to deflation.

gastric and esophageal cells is immediately placed in a beaker containing 100 cc. of isotonic sodium chloride solution. A perforated rubber stopper is placed over the cylinder, which keeps the balloon entirely immersed in the physiological medium. Through the small opening in the rubber stopper, the tube is jiggled up and down in order to free the mucoid cellular particles. The sodium chloride solution becomes cloudy with a large amount of floating cellular material. Some of the malignant cellular clusters may even approach the size of pathological biopsy material. When the surface of the balloon is completely cleansed of cells, the balloon is withdrawn, detached from the apparatus, and destroyed. The apparatus is subsequently cleansed and sterilized preparatory to the attachment of a clean unused abrasive gastric balloon. Throughout the procedure, there is usually no regurgitative vomiting experienced from the fasting stomach. While in the stomach the actual distance that the balloon traverses varies with the length of the balloon and the distensibility of the stomach. An abrasive balloon 20 cm. long almost fills the gastric cavity. A 10 cm. balloon, being shorter, may traverse the stomach over a greater distance to afford an increased abrasive effect.

The specimen of cells contained in the sodium chloride solution represents the entire surface area of gastric and esophageal mucosa. The specimen is placed in two 50 cc. centrifuge tubes. The tubes are centrifuged at 2,500 revolutions per minute for 5 or more minutes. The longer the period of sedimentation the better the cell concentration at the bottom of the centrifuge tube below the mucous layer. After decanting, the sediment is utilized in the preparation of smears. The cellular material is placed on a clean glass slide and spread evenly by means of pressure through another glass slide. Superimposition of the cells may be minimized by making thin smears. A wire loop method of smearing cells may be used. Prepared within a 15 minute period, the gastric smears are placed immediately into a mixture of equal parts of ether and 95% ethyl alcohol to fix the cells. Three slides should suffice for diagnostic purposes. Following fixation the smears are ready for future staining by the Papanicolaou technique. With this procedure, the improved stomach explorer has been tested and found to be satisfactory for gastric diagnosis.

COMMENT

To pass the abrasive balloon into the stomach for cytological diagnosis is no more difficult than to insert a stomach tube through the nose for gastric analysis. The criteria for the use of the abrasive gastric balloon test is the suspicion of a malignant gastric lesion. Age is not a factor, the older age group of patients tolerating the examination extremely well. While the abrasive balloon is in the stomach, it makes immediate contact with the entire mucosal surface. The particles of mucoid cellular material represent, for the most part, abnormal shedding tissue. It is already known that normal gastric mucosa resists mechanical exfoliation. In many ways, the gastric smear is a concentrated reflection of the entire stomach surface. The cytological interpretation of the gastric smear is an integrated picture of the histological and pathological status of the stomach mucosa. The final interpretation may be read as negative or positive for malignant disease, although occasionally an abnormal smear will occur giving a suspicious negative result.

Untoward effects from the abrasive gastric balloon have not been encountered. Gastric ulcers have progressed to healing without event. Accentuation of bleeding has not occurred in patients who have had recent gastric hemorrhage; however, the use of the abrasive gastric balloon test is being avoided in the presence of active gastrointestinal hemorrhage, known esophageal varices, or esophageal obstruction or postoperatively in cases of gastric resection.

How should the abrasive gastric balloon test be used as a diagnostic screening test? The stomach of the patient may be investigated cytologically if he shows (*a*) early symptoms and signs of malignant disease, (*b*) achlorhydria, (*c*) questionable defects seen by gastrointestinal series, or (*d*) suspicious mucosal lesions seen by gastroscopic examination. The individual gastric suspect may be handled in the clinic quickly by first securing a gastric analysis and then performing an abrasive gastric balloon cytological examination. In this way, the achlorhydric stomach would be screened, and the retentive stomach could be recognized for adequate preparation.

If a positive gastric smear is obtained, the problem immediately becomes surgical in nature, and consideration of exploratory laparotomy is warranted. Since carcinoma of the oropharynx may be recognized by direct examination and carcinoma of the duodenum is almost nonexistent, a general localization of the lesion to the stomach or esophagus can be made by cytological examination. If a more definite localization of the lesion within the stomach is deemed necessary, then a gastrointestinal series and a gastroscopic examination may be secured. If a negative or suspicious negative gastric smear is obtained, the problem should be surveyed further by means of an upper gastrointestinal series and gastroscopic examination, along with any other gastric tests that may be utilized. Material obtained from the abrasive gastric balloon yields a sufficient quantity and quality of cells from the stomach and esophagus to minimize the number of false negative and false positive results reported prior to development of the balloon technique. Gastric smear readings for malignant disease can be depended on to have a satisfactory degree of accuracy. As a result of the development of this technique, gastric cytology has become a growing field that offers one potential key to gastric diagnosis.[2]

SUMMARY

The application of the abrasive gastric balloon offers a convenient diagnostic means for revealing gastric malignant disease. The technique is adapted to quick office procedure.

PRESENT ROLE OF ZINC PEROXIDE IN TREATMENT OF SURGICAL INFECTIONS

Frank Lamont Meleney, M.D., New York

The antibiotics have so completely taken hold of our minds in the treatment of surgical infections that we are often forgetful of other methods of treatment that are available. I have frequently been asked whether, since the arrival of the sulfonamides and the antibiotics, there are any conditions for which medicinal zinc peroxide is superior to these other chemotherapeutic agents. Experience has demonstrated that there are certain infections that are more amenable to treatment with this agent than to treatment with the antibiotics and that, if medicinal zinc peroxide is properly used, it will bring about the control of the infection and healing of the wound more quickly than will any other form of treatment.

There are two regions of the body where this drug is of particular value: on the outer surface of the skin and along the alimentary tract. It can be used for the interior of the body only if there is a cavity with an opening from which the residue may be readily removed.

LIMITATIONS AND VIRTUES OF ZINC PEROXIDE

The limitations of the drug as well as its virtues must be kept in mind. The limitations are as follows: 1. It must be an active preparation of "medicinal grade" capable of producing nascent oxygen whenever water is added to it. 2. It must be suspended in sterile distilled water so as to form a thick creamy suspension and be applied on cotton or fine mesh gauze in close contact with the infected surfaces. 3. It must be kept wet.

A test to determine the effectiveness of the drug can be easily performed. If a small amount of the powder is placed in a test tube and covered with twice the quantity of water, within an hour the supernatant water will become clear, the sediment will become curdy, and bubbles of oxygen will form in the curd and will gradually lift it to the top of the test tube. Ineffective zinc peroxide will remain at the bottom of the test tube as an inert mass, which may cake, and no oxygen bubbles will be generated.[1]

Before use, zinc peroxide should be sterilized in a dry oven for four hours at 140 C. This not only sterilizes it but renders it more active. Sterile zinc peroxide may be kept in test tubes or bottles for many months without significant deterioration. As far as I know, only the DuPont Chemical Company has been able to make the active "medicinal grade" zinc peroxide, and at present Mallinckrodt Chemical Works is the only company distributing it.

The virtues of the drug are as follows: 1. It will rapidly destroy anaerobic and microaerophilic organisms and inhibit a wide variety of aerobic bacteria. 2. It is particularly effective in the presence of mixed infections. Both proteus and pyocyaneus organisms are inhibited by it when it is used in the concentrations generally employed. 3. It is completely nontoxic and nonirritating to the tissues. 4. After the drug gives off its oxygen, relatively bland zinc oxide and zinc hydroxide remain, which are well tolerated by the tissues. 5. It is a detoxifying agent, inactivating almost every kind of bacterial toxin. 6. It apparently stimulates the growth of healthy, well-vascularized, firm, granulation tissue, which hastens wound healing and permits early skin grafting. 7. It will control hemorrhage from infected surfaces.[2] 8. One very fortunate attribute of zinc peroxide is that it does not stick to the tissues even when applied on cotton. The outer surface must be kept wet so that the dressing will not adhere to the tissues.

Zinc peroxide is most active when used in a watery suspension, but it may be incorporated in a carbowax® (polyethylene glycol) water-soluble base when it is used on areas difficult to keep moist. This ointment may be prepared in any pharmacy with 40 parts of carbowax® 1540, 40 parts of carbowax® 300, and 20 parts of activated zinc peroxide. The carbowaxes® are melted together over a free flame and then sterilized in a dry oven at 140 C for two hours. The mixture is then allowed to cool; as it begins to solidify, the activated zinc peroxide is added. It is mixed well with an egg beater and placed immediately in the refrigerator. It is again stirred with a rod just before solidification and then refrigerated until it is solid. Reid and Altemeier found that 1% calcium peroxide might be combined with 10% zinc peroxide in such a base; the combination seemed to be more effective than zinc peroxide alone.[3]

ULCERS AND OTHER SKIN INFECTIONS

Undermining Burrowing Ulcers.—It was with the undermining burrowing ulcers that medicinal zinc peroxide first demonstrated its clinical usefulness.[4] This lesion is caused by a microaerophilic hemolytic Streptococcus that has a propensity for burrowing in the subcutaneous tissues and down in between muscles and along lymphatic channels. It frequently involves neighboring lymph nodes, and the infection often smolders there until the nodes are surgically removed. These ulcers are chronic, often lasting years until the proper treatment is administered. The infection frequently burrows through the skin from beneath. Starting as a pinpoint opening, a daughter

ulcer may form, gradually enlarge, and then either fuse with the main ulcer or leave a bridge of skin that is completely surrounded by epithelium. The value of medicinal zinc peroxide in the treatment of these ulcers has been amply confirmed.[5]

It is obvious that the local application of any medicament may not reach every part of the infected surface and its activity certainly will not readily spread up to the neighboring lymph nodes, if they are involved. The blood vessels in the periphery of such lesions are usually blocked by blood clots, making it difficult for any medicament given systemically to reach the infected surface from the inside. If contact cannot be maintained with every part of the infected surface, it becomes necessary to excise the lesion and the grossly involved lymph nodes *in toto*. Then the application of medicinal zinc peroxide on the raw surface quickly disposes of the microaerophilic hemolytic Streptococcus and all other susceptible organisms. Cultures have been made during the course of wound healing in numerous cases in which this treatment was used. The first cultures, particularly those obtained from the innermost recesses of the wound, show the microaerophilic hemolytic Streptococcus, but within 24 to 48 hours the progeny becomes aerobic. With continued treatment the organisms become green. Soon afterward they disappear from the wound.

Progressive Bacterial Synergistic Gangrene.—There is one type of gangrenous ulcer of the skin that has characteristic clinical features. This is due to the presence of a microaerophilic nonhemolytic Streptococcus and a Staphylococcus aureus. It is therefore called synergistic gangrene and is inexorably progressive unless it receives the proper treatment.[6] Its pathognomonic symptom is extreme pain and tenderness, and it is readily recognized by its typical three zones: an outer erythematous zone, a middle raised purple necrobiotic zone, and an inner zone of "suede leather" gangrene. It often starts in an infected operative wound, particularly one that has drained a putrid abscess of the abdomen or chest, and one that has been closed with retention sutures. The tension of these sutures seems to establish the conditions under which the microaerophilic nonhemolytic Streptococcus can gain a foothold.

A number of authors have reported cases of synergistic gangrene and have stated that they have treated the condition with zinc peroxide without effect, but it is obvious that medicinal zinc peroxide or any other medicament applied locally could never reach the spreading periphery of this lesion. In order for one to treat it with medicinal zinc peroxide, it is necessary first to widely excise the lesion beyond the zone of erythema. Then closely applied medicinal zinc peroxide suspension will kill the microaerophilic organism and will prevent a recurrence of the infection. However, it has recently been demonstrated that this condition can often be cured and surgery obviated by the systemic administration of bacitracin.[7] Medicinal zinc peroxide, therefore, should not be used for treatment of this lesion unless the organisms are resistant to both penicillin and bacitracin therapy. Then excision becomes necessary.

Other Ulcers and Skin Lesions.—There are various other kinds of ulcers that may occur on any part of the body surface but are particularly prevalent on the legs. If infection plays a major part in their occurrence or in their persistence, many of them respond to treatment with medicinal zinc peroxide, especially those caused by the hemolytic Streptococcus or the hemolytic Staphylococcus aureus. Hemolytic streptococci promptly disappear from ulcerated surfaces when medicinal zinc peroxide has been applied. Most of these ulcers do not have the typical undermined and rolled in edges, which are characteristic of, and should not be confused with, the undermining burrowing ulcer.

Decubital ulcers clean up and heal more rapidly if medicinal zinc peroxide is employed on cotton balls or flat cotton wet with a suspension of the powder in water and kept moist with an overlying layer of wet flat cotton sealed with a double thickness of zinc oxide ointment gauze.

Other skin lesions that are particularly amenable to treatment with medicinal zinc peroxide are the very common exudative lesions produced by contact with the leaves, branches, or roots of poison ivy and poison oak. If medicinal zinc peroxide powder is applied to the lesions in the form of a lotion, they usually dry up quickly and spread no further. A rapid cure almost invariably results, probably owing to the detoxication of the Rhus toxin. The pain and vesiculation of herpes zoster is also amenable to medicinal zinc peroxide treatment. Again the medicament should be applied in the form of a lotion, which can be renewed at frequent intervals.

In the foul-smelling gangrenous lesions of the extremities in diabetes or arteriosclerosis, the use of medicinal zinc peroxide will prevent the activity of the odoriferous organisms and sometimes permit healing after conservative removal of the dead tissue.[8]

Gas Gangrene.—The results of medicinal zinc peroxide therapy in both experimental and clinical gas gangrene are somewhat equivocal, probably because of the difficulty of getting and maintaining contact with the area of infection.[9] With excision of the necrotic muscle, however, treatment with medicinal zinc peroxide has been found able to take care of the residual infection. The benefit obtained by intramuscular and local application of bacitracin and the oral administration of aureomycin and chloramphenicol may well take the place of medicinal zinc peroxide in the treatment of this condition.

Putrid Lung Abscess.—In foul-smelling lung abscesses that have been surgically drained, medicinal zinc peroxide may be instilled and gently applied on cotton balls, with prompt disappearance of the putrid odor, which is due to the anaerobic streptococci, spirochetes, and fusiform bacilli.[10]

Human Bites.—Lesions resulting from human bites often fall into the same category as lung abscesses as far as the bacteriologic aspects are concerned, and medicinal zinc peroxide is effective both in the prophylactic and in the active treatment of these wounds.

ALIMENTARY TRACT INFECTIONS

Mouth and Throat Lesions.—Infections along the alimentary tract are successfully treated with medicinal zinc peroxide, for example, ulcerative stomatitis and Vincent's infection of the mouth and gums.[11] Often the pain of sore throat produced by the hemolytic Streptococcus is promptly relieved by the use of medicinal zinc peroxide. This may be applied to the surface as a mouthwash or gargle, or, in order to maintain contact with the infection for as long a time as possible, it is a good practice to make a thick suspension of medicinal zinc peroxide on a flat piece of wet cotton and apply it directly to the lesion, maintaining contact for an hour at a time several times a day. The tonsils and pharynx may be swabbed with cotton on an applicator wet with the zinc peroxide suspension. Medicinal zinc peroxide may be used as a prophylactic before plastic operations on the mouth or before dental extractions. After extractions it may be applied on a small pledget of cotton directly into the tooth socket.

If infections occur from the mouth organisms spreading down into the neck with a rapid breakdown of the nodes and surrounding tissues, after incision for drainage, medicinal zinc peroxide may be applied to the abscess cavity, with a rapid resolution of the infection.[12] The foul odor of these infections is due to gas-forming anaerobic streptococci with or without spirochetes. When their growth and activity is prevented by treatment with medicinal zinc peroxide, the odor rapidly disappears.

Mediastinal Infections.—Likewise, the foul-smelling abscesses that form in the mediastinum or in the pleura after perforation of the esophagus, by a foreign body, by an ulceration, or by a dilating instrument, respond to zinc peroxide after surgical intervention, because the most important organism in such infections is a gas-forming anaerobic Streptococcus. Medicinal zinc peroxide cannot be given by mouth because it causes nausea when it reaches the stomach, unless it is taken in enteric-coated capsules. However, only small quantities can be delivered to the intestine in that way. The antibiotics and the sulfonamides are more dependable for reducing the susceptible organisms of the intestine.

Ulcerative Colitis.—In ulcerative colitis, medicinal zinc peroxide may be extremely useful.[13] If the lesion is limited to the lower part of the large bowel in the rectum and sigmoid, medicinal zinc peroxide may be delivered by retention enemas. In some cases when there is extensive ulceration and extreme irritability, it cannot be retained very long at first, but, if it is so introduced and expelled, it leaves a coating of zinc peroxide that has an inhibiting effect on the growth of anaerobic organisms and favors the healing of ulcerations. With repeated instillations it can be tolerated for a longer and longer time. However, if a retention enema containing medicinal zinc peroxide, 6 to 8 oz. (170 to 227 gm.), cannot reach the upper limits of the lesion, it is necessary to perform a cecostomy and deliver it above the lesion, so that it may reach all of the infected surfaces. In many cases delivering it in this way results in rapid healing of the ulcerated area of the intestine from the cecum downward, even when the drug is mixed with fecal material. However, in some cases in which the ulceration is extreme, it is better to perform either an ileostomy or a colostomy above the lesion, thus cutting off the fecal stream and giving the medicament a better chance to act on the ulcerated areas of the mucous membrane. I feel certain that, with medicinal zinc peroxide therapy, a colectomy can be avoided in some cases or a less extensive colectomy than would otherwise be required can be performed.

Whenever medicinal zinc peroxide is used in an enema or is to be delivered into the cecum or lower ileum, it is advisable to suspend it in a 2% polyvinyl alcohol solution rather than in sodium chloride solution or in water. In this mucilaginous suspension it does not become dry and hard during the dehydration process as the fecal material passes on toward the rectum.

Anorectal Infection.—Medicinal zinc peroxide is extremely useful after operations on fistulous tracts and on hemorrhoids as well as on infected pilonidal cysts. It may be applied in a watery suspension on cotton balls that fit readily into the cavity from which the fistulous tract has been excised or the pilonidal sinus has been removed.[14] After hemorrhoid operations a gauze rol may be soaked in the medicinal zinc peroxide suspensio and inserted into the anus. I have yet to find a patien who objects to the presence of the plug. The gentle pres sure that it exerts tends to stop all bleeding and inflam mation. One is particularly struck by the absence of swelling, redness, and pain around the site of operation. On the second, third, or fourth day this roll may be readily removed from the anal canal, and by that time the danger of infection from intestinal contents has passed.

VAGINAL INFECTION

The organisms most to be feared in the vagina are the hemolytic streptococci, the anaerobic cocci, and the gas gangrene organisms. These are all inhibited and destroyed by medicinal zinc peroxide therapy. Infections of the vagina caused by these organisms are generally quickly brought under control by the nightly instillation of a suspension of this drug. This may also be used as a prophylactic against infection before plastic operations on the vagina and before supravaginal hysterectomy.

AS AN ADJUNCT IN CANCER THERAPY

Those who deal with cancer find medicinal zinc peroxide very useful, particularly in minimizing the foul odor and bad taste of inoperable cancerous lesions of the mouth during and after radiotherapy.[15] In the Memorial Hospital in New York it is employed constantly for these purposes.[16] In cases in which there is a radionecrosis of skin—for example, in the mammary region—medicinal zinc peroxide therapy will prevent odor and favor wound healing. When a colostomy is formed, light packing around it with gauze soaked with a suspension of medicinal zinc peroxide or medicinal zinc peroxide ointment will usually prevent the development of infection in the surrounding tissues and prevent the sloughing of fascia, which may lead to a ventral hernia. After an abdominoperineal resection of the bowel, the perineal cavity may be kept free from infection by instillation of medicinal zinc peroxide and packing of the cavity with a 5 yd. (4.67 meters) gauze roll inside a China silk tampon.

SUMMARY

Medicinal zinc peroxide is still useful in the treatment of surgical infections even though the sulfonamides and antibiotics are available. Only the medicinal zinc peroxide approved by the United States Pharmacopoeia should be used. It is more effective if activated and sterilized by heating the powder in a dry oven at 140 C for four hours. After this procedure it may be kept in sterile containers for several months without significant deterioration.

The most important conditions better served by medicinal zinc peroxide therapy are undermining burrowing ulcers; synergistic gangrene, only after excision; decubital ulcers; other ulcers in which there is a large element of infection; diabetic gangrene; ulcerative stomatitis; foul-smelling lesions of the mouth and neck, especially in the presence of cancer; radiation burns; ulcerative colitis; and nonvenereal vaginitis. It is useful as a prophylactic around colostomies and after dental extractions. It is also very effective for the skin lesions of herpes zoster and poison ivy.

LONGEVITY IN BENIGN ESSENTIAL HYPERTENSION

James P. O'Hare, M.D.
and
Robert B. Holden, M.D., Boston

This is a report of a study of 100 cases of benign essential hypertension followed personally by us for 10 to 34 years. Our purpose in making this study was threefold: (1) to add to the meager volume of valid published data concerned with the ordinary course of this disorder; (2) to seek clues that might explain the long life and favorable course in these cases, thereby increasing our capacity for making accurate prognoses; and (3) to make physicians more conscious of the fact that the course in many hypertensive patients may be a very benign one, compatible with long and effective living. If this last can be accomplished, judgments concerning patients with high blood pressure will be dominated less by the end-stages of this disorder, with its dreaded hemiplegia, heart failure, or uremic poisoning, and patients should receive better and more reasonable therapy than many now do. It is our hope that this paper may also dispel much of the confusion created by the literature concerning length of life in patients with hypertensive vascular disease.

Reports concerned with mortality rates among patients with hypertensive vascular disease have been contradictory. For example, Ranges[1] reported no deaths whatsoever among 241 patients observed for 10 to 25 years, whereas Hamman's[2] 10-year death rate was 78%. Statistics from other authors fluctuate markedly between these extremes. Such apparent lack of unanimity is readily explained by analysis of the various methods of selection used by different authors. Cases of mild disease predominate in some papers[1] and cases of severe disease in others.[3] In many,[4] cases of both benign and

malignant disease are grouped together. Some authors[5] make little if any distinction between the various diseases that have hypertension as a common factor. Some publications deal only with special groups, such as those that have come under the scrutiny of insurance companies.[6] The reports of Hamman,[2] Paullin,[7] Riesman,[8] Rice,[9] and Burgess[10] deal exclusively with private patients. Most of the other writers have utilized only hospital or clinic patients. Their papers have the inherent weakness of being essentially collections of data taken from hospital records. The observations recorded had been made by numerous observers with varying interests and standards of accuracy.

Some of the confusion has been dispelled in the last few years by the excellent articles of Burgess,[10] Blood,[11] Perera,[12] Palmer,[13] Ranges,[1] Smith,[14] and Griep.[15] Many more will have to be written with data carefully determined and compiled by uniform methods before adequate information is available.

Papers based on a continuing series of documented observations made by trained persons are few indeed. Seventy-eight per cent of our patients were private patients of one of us (J. P. O'H.). Twenty-two per cent were patients in the clinic at the Peter Bent Brigham Hospital, and all the observations on them were made by one of us (J. P. O'H.) or his associates.

Cases were selected on the basis of (1) a documented history of 10 or more years of hypertension (systolic 145 mm., diastolic 95 mm., minimum); (2) absence of primary renal disease (glomerulonephritis or pyelonephritis); (3) absence of coarctation of the aorta, valvular heart disease, hyperthyroidism, and similar disorders causing hypertension; and (4) absence of any radical therapy, such as sympathectomy and rice diet. (A very small group of these patients, in their early years, had an unsuccessful trial with diet extremely low in salt. Another small group received "cyanate" therapy for a few weeks.) Excluding these few, the condition in all patients was classifiable as benign essential hypertension treated throughout by conservative methods only, i. e., sedation, weight reduction, and general advice.

Of the entire group of 100, all were white and predominantly of Irish, American, or Jewish extraction; 67 were women and 33 men. The age distribution at the time of discovery of the hypertension ranged from 21 to 68 years, with an average of 45 years. Initial systolic pressures varied from 130 mm. to 250 mm.; diastolic pressures from 80 mm. to 140 mm. (Normal systolic pressures were accompanied by elevated diastolic pressures and vice versa.) The period of documented hypertension ranged from 10 to 34 years, with an average of more than 17 years. Since 71% of these patients are still alive, including our "34-year" patient, this range and average will in all probability increase. A breakdown of the group by five-year periods is shown in table 1.

TABLE 1.—*Duration of Hypertension*

Period, Yr.	No. of Patients	No. Living	No. Dead
30-34	4	3	1
25-30	8	5	3
20-25	11	8	3
15-20	42	31	11
10-15	35	24	11
Total	100	71	29

It is particularly impressive that 23 patients have lived 20 or more years (average 25) with their hypertension and that 16 of these are still alive and have a fair chance of living several more years.

Of the group of 71 still alive, 47 are in "good" condition, 19 in "fair" condition, and only 5 in "poor" health. Such data clearly point to the fact that essential hypertension may be compatible with relatively long life. Furthermore, such long life has been, with some exceptions, reasonably comfortable and effective.

Thus far only 29 of our patients have died. The causes of death are indicated in table 2. The incidence of cerebral accident and myocardial failure among these 29 is at variance with that in other published data. However, this is a very small group; when death eventually comes to the entire 100, the percentages, in all probability, will be quite different. It should be noted, too, that the figures in table 2 represent only the principal cause of death. Few patients have escaped one or more of the complications commonly associated with hypertensive vascular disease. For example, coronary insufficiency has been noted at some time in 51% of the entire group of 100 patients. In the 29 who have died, this symptom had occurred in all but 8. Coronary thrombosis, though listed as the principal cause of death in only 8 patients, occurred at least once in 12 others. Myocardial failure was the chief cause of death in only 3 patients, and yet it was noted in 19% of the entire group and played a prominent role in 13 patients who died. This disorder appeared late in the disease, usually during the last two years of life. Cerebral vascular accident, credited with being the principal cause of death in 14 patients, occurred in 28 of the entire group. Chronic nephritis developed in 12 patients but played a significant role in only one of those who died. Diabetes

TABLE 2.—*Principal Cause of Death in Twenty-Nine Patients*

Cause	No. of Patients
Cerebrovascular accident	14
Coronary thrombosis	8
Myocardial failure	3
Cancer	1
Auto accident	1
Unknown	2
Total	29

mellitus was noted in nine patients but was an important feature in only three of those who died.

In any disease as prevalent as hypertension, it is obvious that observations on 100 patients, even when such observations are as numerous and accurate as ours, may not be statistically significant. Others, no doubt, will record similar observations, and eventually there will be accumulated sufficient accurate material to make the total significant. Nevertheless, we would be remiss if at this time we did not analyze our voluminous data to check the clinical impressions gained from these patients and to seek clues that might explain their longevity and their favorable courses. We believe the results are of considerable interest and importance, particularly with respect to the light they throw on the course of benign hypertension and the suggestions they offer for making more satisfactory prognoses.

It may be suggested, with some degree of justice, that ours is an exceptional group. To the extent that these patients were deliberately chosen because they had essential hypertension, had lived with this disorder at least 10 years, and had accurate documentation, this is correct. We have no means of knowing what percentage of the total number of patients with essential hypertension is represented by patients with such benign disease. Too few groups have been followed for 10 or more years to permit us to answer this question. We strongly suspect that the percentage is far greater than is commonly believed.

It may be argued that the group is not truly representative, since four-fifths of the patients were private and only one-fifth clinic patients. It can be truthfully stated that as a whole the patients were from typically "middle-class" American families. Few were wealthy, and few were very poor. Practically none was able to give himself exceptional care. Not more than 4 out of the entire 100 could be said to be even reasonably free from strains of one kind or another, real or imagined.

Our series contains a high proportion of women (67 women to 33 men). This proportion is, however, in keeping with that considered usual by Boas [16] and by Blackford.[17] It is generally agreed that women as a class withstand hypertensive disease better than do men. Our data support this conclusion. It is of considerable interest to note that of the 23 patients who have lived the longest (20 or more years) only 5 were men.

AGE AT ONSET

The predominance of the younger age group among the patients with chronic nephritis or "malignant" hypertension must account, in part at least, for the generally accepted opinion that the younger the age when hypertension starts, the poorer the prognosis, and the older the age at onset, the more favorable the outlook. While this statement is generally true, there must be many exceptions. Some of these are found in this series. In our patients, all of whom had high blood pressure for at least 10 years, the age at discovery ranged from 21 to 68 years, with an average of 45 years. In 5 patients the disease began before age 30 and in 28 before age 40.

It is of additional interest to note in the 23 patients who have lived the longest—20 or more years—that 10 were discovered to be hypertensive before they were 40 years of age and one before he was 30. Furthermore, of the 28 with onset before 40 years, only 8 have died. Perhaps the ratio of 20 women to 8 men in this group may be a factor.

RANGE OF BLOOD PRESSURES

With three important exceptions, to be discussed later, blood pressure levels, per se, in the individual patient were of little value in helping us to determine his true condition and make a prognosis. This is particularly true of the initial readings. These readings in some patients were exceedingly high, reaching in one, a top level of 250/140. The lowest initial recording was 130/80. (Sub-hypertensive systolic and diastolic levels were associated with corresponding hypertensive diastolic and systolic readings.)

False conclusions could easily have been drawn—and probably were—from such high figures, undoubtedly recorded at times of great stress. It should be again pointed out that all these patients lived at least 10 years after such high levels were observed. In the group that have lived 20 years or more, the initial blood pressure was found to be as high as 224/120. Three of this same group had initial systolic pressures over 200, and 2 had diastolic levels over 120. (It seems reasonable to draw another inference from these high first readings: that these patients probably had had increased pressure for some time previous to its discovery.)

Throughout the years of observation, the highest systolic pressure was 300 and the highest diastolic pressure 170; the lowest systolic pressure was 108 and the lowest diastolic pressure 60. The range of individual variations was as follows: systolic 20 to 150 (average 68) and diastolic 10 to 81 (average 40).

Over the years, too, individual blood pressure readings and curves of pressures by themselves contributed little toward a proper prognosis. Wide variations, in the forms of peaks or slower wave-like rises and falls, were the rule. There was little "trend" pattern and, except in a group of 17 patients, little constancy or stabilized levels of pressure.

These 17 patients are of particular interest in that, throughout their courses, they have never shown pressures above 180/120. Six of these are in the group of 23 who have lived more than 20 years. One is still alive and well after 34 years of such hypertension. Four patients have constantly shown diastolic levels of 110 mm. or less. Only 4 of the entire 17 have died, all with serious heart failure. Patients of this type, who maintain a constant low level of hypertension for months or years, are exceptional, and the statement made previously that blood pressure levels, per se, gave little indication of the ultimate prognosis, is not true of them. A second exception is the type of patient having progressive, steady rise of diastolic pressure into high levels, foreboding strain on the whole circulatory apparatus. However, this occurred rarely in our group, and then only near the end of life.

AVERAGE BASAL DIASTOLIC BLOOD PRESSURE

In the group that has lived 20 years or more, the average basal[18] diastolic pressure was 91 mm. The average in the entire group was 95 mm. and in those that had died, 99 mm. The most important exception to the generally poor prognostic value of blood pressure readings, and one of the most important conclusions we have been able to draw from our studies, is that low basal diastolic pressures suggest a favorable course. It seems highly significant that these patients, who have at times shown such extremely high levels of systolic and diastolic pressure and yet have lived so long and so well, have had basal diastolic pressures that averaged throughout the years only 95 mm. For the 23 who have lived an average of 25 years, the average "basal" diastolic pressure was even lower (91 mm.); for the 29 dead, who lived an average of 17 years, it was somewhat higher (99 mm.).

In our judgment, basal diastolic pressures represent more nearly the ordinary day by day, hour by hour, arterial pressure and circulatory strain than do the higher "spot" readings made in the physician's office or in the hospital, readings so often affected by the emotional strain of the examination.

Summarizing the analysis of our data on blood pressures in this group, we conclude that, with two important exceptions, single readings at any given time, or multiple readings over long periods, by themselves, were of little help in prediction of the course of the disease. The two exceptions were in (1) the relatively small group of patients whose pressures were stabilized at comparatively low levels of hypertension, and (2) those with low average basal diastolic pressures. We may also conclude that, in these 100 patients, the degree and constancy of strain were far less than were suggested by the frequent high levels of blood pressure recorded.

FUNDI

For many years we have believed that careful examination of the fundi was one of the most fruitful studies that could be made of the hypertensive patient. We felt that the degree of retinal arteriolar sclerosis revealed the results of strains and the seriousness of the disease better than any other single sign until the appearance of the advanced cardiac and cerebral changes that presage the "end of the road." Sporadic hemorrhages and white spots, except in association with severe retinal arteriolar sclerosis or papilledema, seemed to have little prognostic value. The analysis of the data in this series confirms our previous opinions.

It is extremely significant that of 98 patients the results of whose most recent examinations were satisfactory, only 22 showed marked arteriolar sclerosis (grade 3). One-third never revealed more than a moderate amount (grade 2), and almost one-half with all their years of hypertension, still had only grade 1 arteriolar sclerosis. The older group, those with more than 20 years of high blood pressure, are even more interesting, in that 6 of the 22 had grade 1, 8 had grade 2, and only 8 had grade 3 arteriolar sclerosis. The slight increase in the number with grade 3 arteriolar sclerosis among the group of dead patients is hardly significant, since it is to be remembered that even these patients averaged 17 years of high blood pressure.

As indicated in table 3, the relative infrequency of advanced changes in the retinas and disks speak for themselves. Only three of the entire group had many hemorrhages and/or exudates, and none had severe papilledema.

Since the arterioles are the blood vessels most concerned in the hypertensive process, it seems reasonable to infer that these vessels in our long-lived patients tolerated the pressures very well and that the strains, in spite of the occasional high pressures recorded, were not so great as might have been expected. This idea fits well with that indicated by the low level of basal diastolic pressures previously mentioned.

ELECTROCARDIOGRAPHIC AND ROENTGENOGRAPHIC OBSERVATIONS

Two other divisions of our data seem to point in the same direction: the electrocardiographic and roentgenographic observations of the hearts.

TABLE 3.—*Observations of the Fundi*

Arteriolar Sclerosis

No. of Patients	Grade 1	Grade 2	Grade 3
Total, 98 *	43	33	22

Dead, 28 †	23	2	2	1

* *Apparent discrepancy in numbers* is due to lack of recent observations or to inadequate observations because of cataracts and the like.
† Lived an average of 17 years.

Among 91 patients, the electrocardiographs showed normal axis in 26, left axis deviation in 50, left axis deviation with left ventricular hypertrophy in 14, and left ventricular hypertrophy alone in 1.

In the light of the previously expressed opinion concerning the degree of strain, it is important to note that 26 of the group of 91 have never shown anything but a normal axis, never having showed even the left axis deviation so commonly associated with hypertension. Only 15 revealed the greater strain indicated by the left ventricular hypertrophy pattern.

Of course, there were other electrocardiographic abnormalities of greater or lesser magnitude. The most common was a progressive slight lowering of the T waves in the four principal leads. This change was noted in 49 patients. Inversion of T waves in these same leads was next in frequency, discovered in 36 patients. Diphasia of T waves developed in 15. Premature beats, both auricular and ventricular, were more often heard than recorded in our tracings, only 11 of which revealed these common abnormalities.

---

[18] The term "basal" as used here differs somewhat from the usual understanding of that term. In the earlier days no such readings were made. The term as we have used it refers to the lowest "spot" readings, in three or five-year periods, according to the amount of available data. True basal readings would, no doubt, have been even lower.

In the patients with more serious cardiac involvement, major electrocardiographic changes were recorded. Heart block, varying in degree from a prolonged P-R interval to bundle branch block, was noted in seven of the group. In the 20 instances of myocardial infarction, the diagnosis was confirmed by characteristic electrocardiographic patterns.

Roentgenograms of the heart in 61 patients showed no enlargement (10% or less) in 41 and enlargement (15 to 40%) in 20. Lack of strain and wear and tear is still further suggested by roentgenograms of the heart taken at a distance of 7 ft. and fluoroscopic examination. Two-thirds of the patients who had satisfactory x-ray examinations late in the period of observation revealed no significant enlargement of this organ. It should be said, however, that fluoroscopic study almost always revealed a prominent left ventricle. Many showed elongation and tortuosity of the aorta; a few showed calcification of this vessel. Most of those with large hearts had coronary artery disease. However, several patients with known coronary symptoms had normal-sized hearts.

COMPLICATIONS

In trying to account for the long course of these patients, we sought to ascertain whether they had been unusually free from the complications that so often accompany hypertensive vascular disease. Table 4 suggests that they were not. However, it is a fact that these disturbing complications occurred late in the disease with few exceptions, and often they contributed to the terminal event. As seen in table 2, cerebrovascular accident was the cause of death in 14, coronary thrombosis in 8, and congestive failure in 3.

TABLE 4.—*Incidence of Complications*

Complication	Among 100 Patients	Among 29 Dead
Cerebrovascular accident	28	15
Coronary insufficiency	51	21
Coronary thrombosis	20	12
Congestive failure	19	13
Chronic nephritis	12	9

Angina pectoris always warrants caution in the prognosis; yet, 12 of the 51 patients who had this symptom lived many years after the initial attack. One patient had her first severe attack 26 years before her death. In some of these patients, pain occurred irregularly over several years. A few had several attacks followed by long intervals of freedom, indicating, probably, the development of collateral channels. The prognosis for patients with angina pectoris, though always uncertain, is far from hopeless and may be compatible with many years of life. Even coronary thrombosis may be followed by several years of comfortable living, as it was in 7 of the 20 patients who had such a complication. At least six patients who experienced a cerebral vascular accident have lived 2 to 13 years after the first "stroke." One is still alive after 13 years.

Two complications were invariably late in these patients: congestive failure and uremia. The former rarely developed earlier than two years before death. It was always serious. While slight proteinuria was noted at some time or other in 58% of our series, true chronic nephritis developed in only 12 patients and played a prominent part in the death of only one. The progress of renal failure was very slow, but, when it became marked, the end was near.

The presence of any of these circulatory complications warrants a cautious but not hopeless prognosis in all patients with hypertensive vascular disease. Their absence warrants a more favorable outlook. Ten of the 23 patients who have lived 20 or more years with their hypertension never showed any of these symptoms or signs. By contrast, all but one of the patients who have died (and he from cancer of the pancreas) have had one or more of these complications.

SUMMARY AND CONCLUSIONS

A study of 100 patients with benign essential hypertension followed by the authors for 10 to 34 years (average 17+ years) is presented. Seventy-one per cent are still alive, and only five of these are in poor condition. Reasonable explanations for their longevity and generally favorable course seem to be the predominance of the female sex in this series and objective evidence that the circulatory strains were not so great as the generally high levels of pressure recorded suggested.

This evidence suggests that the determination of "basal" diastolic pressures and the careful evaluation of the degree of retinal arteriolar sclerosis are of maximum importance in making accurate prognoses in patients with hypertensive vascular disease. Of lesser importance, perhaps because less readily available, are electrocardiographic and roentgenographic observations of the heart.

This report indicates that essential hypertension may be compatible with a relatively long and effective life. One must give this fact serious consideration in making prognoses and planning therapy, to avoid creating "blood pressure neurotics" and subjecting patients to difficult, expensive, prolonged, and often ineffective treatment.

520 Commonwealth Ave. (Dr. O'Hare).

Cervical Lymphadenopathy.—Asymmetric enlargement of one or more cervical lymph nodes in the adult is almost always cancerous and usually is due to metastasis from a primary lesion in the mouth or pharynx. The foregoing statement may appear dogmatic, but as a basic principle for the physician's clinical attitude toward cervical tumors it will prove to be both sound and dependable, and will result in the early discovery of many cryptic primary growths. . . . The phrase, usually due to metastasis from a primary lesion in the mouth or pharynx, is wholly true if the examiner is sufficiently alert and experienced to exclude from consideration such benign and readily recognizable tumors as lipoma, branchiogenic cyst, etc., which are not highly suggestive of metastatic cancer. . . . The crux of the problem . . . is the frequent failure to recognize the probable cancerous nature of cervical tumors in the adult and, furthermore, the failure to realize that practically all malignant cervical tumors are metastatic rather than primary in the neck. Unless he understands the basic nature of this clinical phenomenon, the first physician consulted by a patient with a cervical tumor will not examine the mouth and pharynx for a "silent" primary lesion. In other cases, although the possibility of an oral or pharyngeal growth is appreciated, too much dependence is placed on a single—even cursory—examination. As a result, precious time is lost and the primary growth may advance to an incurable stage before it is discovered.—Hayes Martin, M.D., and Claude Romieu, M.D., The Diagnostic Significance of a "Lump in the Neck," *Postgraduate Medicine*, June, 1952.

CORTICOTROPIN (ACTH) IN THE TREATMENT OF ACUTE SUBACROMIAL BURSITIS

Charles LeRoy Steinberg, M.D.
and
Andries I. Roodenburg, M.D., Rochester, N. Y.

The multiplicity of "successful" treatments advocated for subacromial bursitis indicates that failures are common. Various treatments that have been used are injection of the subacromial bursa with procaine hydrochloride, iron cacodylate injections, short wave local treatment, hot moist packs, immobilization, surgical excision of the bursa, radiation therapy, and manipulation of the shoulder with the patient under a general anesthetic. Radiation therapy has been more or less accepted as being the most efficacious treatment for acute subacromial bursitis. Meyerding and Ivins [1] stated that acute lesions have responded to roentgen treatment in contrast to failure in cases of more chronic lesions. Forty of the 150 patients in their series were treated with roentgen rays. Lattomus and Hunter [2] found that the best results were obtained in the cases of acute disease, either first attacks or acute exacerbations of a chronic condition. Leucutia (in Portmann [3]) stated that the severe pain in the cases of acute subacromial bursitis is relieved by roentgen therapy within 48 hours.

Successful treatment of this condition should accomplish first and foremost relief from the severe pain. The follow-up care should be directed toward obtaining normal or near normal motion of the shoulder joint. The advantages of roentgen therapy are that it is applied easily and is usually effective within 48 hours. However, it is to be noted that at least 50% of patients so treated experience intense aggravation of the shoulder pain and require opiates during this 48 hour period. Another disadvantage to this treatment is that, although relief follows within a period of 24 to 48 hours, a frozen or less obile shoulder joint results unless a carefully planned ogram of physical therapy is soon inaugurated.

The recent dramatic relief of joint symptoms associated with cortisone, hydrocortisone, or corticotropin (ACTH) therapy has stimulated us to study the effects of corticotropin therapy on acute subacromial bursitis. This is usually a self-limiting condition associated with severe pain and disability of the shoulder joint. Since the condition is self-limiting and therefore would require a short period of treatment with corticotropin, none of the complications associated with treatment with this hormone should be encountered. It was therefore tried in the following six patients with various dose schedules.

REPORT OF CASES

CASE 1.—E. O., a white man aged 45, was first seen June 1, 1951. He had had some discomfort in his left shoulder for one week. The pain became intense on May 27, 1951 (four days before treatment was started), after he had lifted approximately 50 lb. (28 kg.). The pain permitted him no sleep at night. There was severe tenderness over the left subacromial bursa. No abduction was possible in the left shoulder. A roentgenogram showed an area of calcification in the bursa. He was given 50 U. S. P. units of corticotropin intramuscularly on two occasions on June 1. When seen three days later, he had normal motion and no pain in the left shoulder joint. He reported that the acute pain in the left shoulder had subsided within a period of three hours after the first injection. He was followed for one month, with no evidence of recurrence. Corrected hourly sedimentation rates were as follows: June 1, 28 mm.; June 4, 21 mm.; June 12, 23 mm.; June 26, 15 mm.; and July 3, 3 mm. At the time of writing there had been no recurrence.

CASE 2.—M. C., a housewife aged 65, was first seen on Sept. 11, 1950. The diagnosis was osteitis deformans (Paget's disease of bone) and a mixed type of arthritis. She was next seen on July 24, 1951, at which time she experienced severe pain in the region of the right shoulder after a day of intensive gardening. Examination revealed severe tenderness over the subacromial bursa and no abduction of the shoulder because of severe pain. She was given 40 units of corticotropin intramuscularly. She reported the following day that the pain had subsided within a period of three hours. There was still 50% limitation of motion of the shoulder joint. She was therefore given 40 units of corticotropin on July 25. Six days later she reported complete relief of all symptoms and a normal range of motion of the right shoulder joint. No roentgenograms were taken. The corrected hourly sedimentation rates were as follows: May 7, 1951 (before the attack of acute subacromial bursitis), 13 mm.; July 25 (one day after the acute attack of bursitis), 26 mm.; and Aug. 21, 14 mm. At the time of writing she had had no recurrence of difficulty in her right shoulder.

CASE 3.—G. B., a white woman aged 35, who did janitor type work, was first seen Nov. 14, 1951, with severe pain in her right shoulder of one day's duration. She awakened at 3 a. m. the morning of Nov. 14 with severe pain in her right shoulder joint. The pain permitted no motion of the right shoulder. Severe tenderness was present over the right subacromial bursa, and no motion was possible in this joint. She was given 80 units of corticotropin intramuscularly, with pronounced relief of pain within three hours. The following day she was able to abduct her right arm to 10 degrees. She was again given 80 units of corticotropin intramuscularly. The following day abduction was possible to 20 degrees. She was given 40 units of corticotropin intramuscularly on Nov. 16 and again on Nov. 17, on which date she was able to abduct her shoulder to 45 degrees. There was no tenderness present and abduction of the right shoulder was normal on Nov. 24. The sedimentation rates remained normal throughout the period of treatment. Roentgenograms of her right shoulder taken Nov. 15 showed an area of calcification subjacent to the deltoid muscle (fig. 1*A*). No calcification was seen in a roentgenogram taken on Dec. 12 (fig. 1*B*). At the time of writing there had been no return of her symptoms.

CASE 4.—P. B., a white man aged 53, was first seen Nov. 15, 1951. He moved a heavy object three days previously and noticed severe pain in the region of his right shoulder. The pain became progressively intense during the next three days. There was exquisite tenderness over the right subacromial bursa, and the slightest touch of his right arm caused the patient to wince with pain. He was given 80 units of corticotropin intramuscular-

2. Lattomus, W. W., and Hunter, L. M.: Roentgen Therapy of Subdeltoid Bursitis: Review of 235 Cases, Delaware State M. J. **21**: 115 (June) 1949.

3. Portmann, U. V., editor: Clinical Therapeutic Radiology, New York, Nelson & Sons, 1950, p. 531.

ly. He was able to abduct his right arm to 60 degrees and had practically no pain the following day. He reported that the pain had subsided within a period of one hour after the first injection. He was given 40 units of corticotropin intramuscularly on Nov. 16. The date of the next dose of corticotropin was Nov. 20, at which time 40 units was given intramuscularly. The patient had complete normal range of motion and no pain the following day. He was able to return to work on Nov. 19. He reported on Nov. 24 that he had been able to work since Nov. 19 without pain. There was complete normal range of motion of the shoulder joints. His corrected hourly sedimentation rates were as follows: Nov. 15, 23 mm.; Nov. 17, 21 mm.; Nov. 20, 18 mm.; and Nov. 24, 18 mm. A total of 160 units of corticotropin had been given.

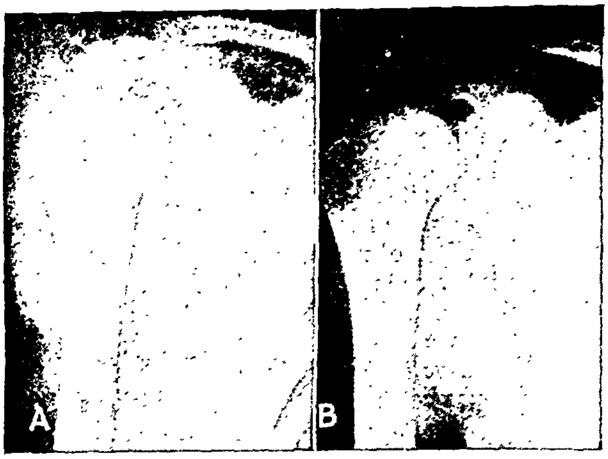

Fig. 1 (case 3).—*A*, calcification in the right subacromial bursa before treatment. *B*, roentgenogram taken one month after the initial treatment, showing the disappearance of calcification in the bursa. The total dose of corticotropin was 240 units. It is usual for calcification to disappear from such bursae in six to eight months after roentgen treatment.

CASE 5.—M. W., a white woman aged 43, was first seen in the office on Oct. 17, 1951. She had had severe disabling pain in the right shoulder one year previously. The right subacromial bursa was aspirated at that time. This resulted in relief of pain, but no increase in joint mobility. She next received roentgen therapy to her right shoulder. The pain in the right shoulder gradually subsided, but pain in the left shoulder, which started after the first roentgen treatment, became more intense. Diathermy directed to the left shoulder joint resulted in no relief of pain. Recently, pain had also returned in the right shoulder joint.

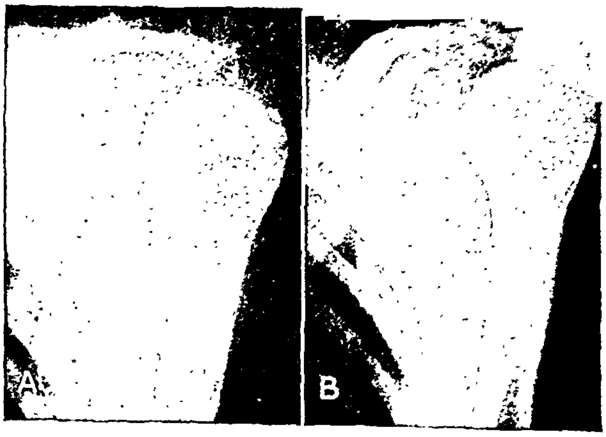

Fig. 2 (case 5).—*A*, calcification in the left subacromial bursa before treatment. *B*, there is little change in calcification of the subacromial bursa three weeks after initial treatment with corticotropin.

Examination on Oct. 17, 1951, revealed a frozen right shoulder joint. Attempts at passive exercise of this joint resulted in severe pain. There was pronounced tenderness over the left subacromial bursa, and abduction was limited to 70 degrees. A roentgenogram of the left shoulder (fig. 2*A*) showed a calcium deposit in the left subacromial bursa. Intramuscular injections of corticotropin were given according to the following schedule:

Oct. 19	20 units
Oct. 20	20 units
Oct. 21	40 units
Oct. 25 and 29	20 units twice daily
Oct. 30	10 units twice daily
Nov. 11	10 units twice daily
Nov. 12	10 units daily
Nov. 13	10 units daily
Nov. 14	5 units daily
Nov. 15	5 units daily

The patient experienced pronounced relief of pain in her shoulder joint about six hours after the first injection. Further relief was experienced by the following day. Abduction of the right shoulder on Oct. 24 was possible to 45 degrees and in the left shoulder to 70 degrees. On Nov. 26, abduction of the left shoulder was possible to 85 degrees and of the right shoulder to 75 degrees. The patient was last seen on Jan. 16, 1952, and reported no recurrence of pain. The range of motion reported above was maintained. Complete range of motion was not possible in the period of observation. The follow-up roentgenograms of the left shoulder showed no change in the calcium shadow (fig. 2*B*).

CASE 6.—K. B., a physician aged 51, awakened early on the morning of Jan. 31, 1952, with soreness and lameness in the right upper arm at the point of insertion of the deltoid muscle. Roentgenographic examination revealed calcification in the right subacromial bursa. Roentgen treatment was given over this area on Feb. 3 and 4, 1952. The pain in the right shoulder became progressively worse after the second roentgen treatment. The physician reported that, on Feb. 5, he took a total of 65 mg. of morphine, 150 mg. of meperidine hydrochloride, some secobarbital sodium, phenobarbital sodium, and acetylsalicylic acid, with no relief of pain. An injection of 25 mg. of hydrocortisone (compound F) was given into the right subacromial bursa on the morning of Feb. 6. The excruciating pain disappeared within a period of three hours after this injection. However, motion of the right shoulder joint was limited to 10 degrees of abduction the following morning, and there was still moderate soreness in the region of the right subacromial bursa. A dose of 40 units of corticotropin was administered intramuscularly on Feb. 7 and again on Feb. 8. Abduction of 45 degrees was present on Feb. 8, and there was only a slight degree of soreness in the region of the bursa. Complete range of motion of the right shoulder joint returned on Feb. 11 and all soreness disappeared. At the date of writing, there had been no recurrence of the condition.

COMMENT

Hollander and co-workers[4] treated three patients with acute and seven with chronic subdeltoid bursitis by local injection of 15 mg. of hydrocortisone. The three patients with acute subdeltoid bursitis responded within a three hour period. The authors stated, "There was complete alleviation of pain and tenderness, and full range of shoulder motion was possible without pain." The relief had persisted for four months in one case and three months in the other two cases at the time their article was written. No other treatment was used. The local injection of cortisone into inflamed bursae in two previous cases produced no such benefit.

Three of their patients with chronic subdeltoid bursitis responded in a similar manner to treatment with a single injection of hydrocortisone. However, in four other cases of chronic subacromial bursitis no relief was obtained even after repeated trial, and in two instances shoulder pain was reported worse for several days after each injection.

SUMMARY

Six patients with subacromial bursitis were treated with corticotropin (ACTH). In five the condition was acute and in one chronic. Roentgenograms of the shoulder were taken in five cases; these showed calcification in the subacromial bursa. Follow-up roentgenograms showed disappearance of calcification within a period of one month in one case and no change in calcification in another case. Complete relief of pain and return to normal function of the shoulder joint was obtained in the five cases of acute bursitis. Complete relief of pain and almost complete return of normal function was obtained in a case of chronic bursitis. We used various dosages of corticotropin in order to determine which dose was optimal. From this study it is suggested that 50 U. S. P. units of corticotropin given twice on the first day and once daily on two successive days is sufficient treatment in the usual case. The ease with which corticotropin may be administered and the clinical response obtained make this method of treatment worth while. Insufficient experience has been obtained with hydrocortisone therapy to determine whether this method is superior. Hydrocortisone must be injected directly into the bursa in order to be effective. This in itself is a problem in some instances. Future experience will indicate the proper role of hydrocortisone in the treatment of this condition. Our present meager experience seems to indicate that corticotropin is more effective than roentgen radiation in the treatment of acute subacromial bursitis.

Treatment of Acute Cholecystitis.—The hazards of acute cholecystitis and its proper treatment are so much greater than the danger of operation at an earlier stage of the disease that every effort should be made to perform cholecystectomy at the time cholelithiasis is first discovered, particularly if it is symptomatic. Serious attacks of acute cholecystitis could thus be largely prevented.

The case fatality rates [in a large series of cases of acute cholecystitis] were significantly affected by the age of the patient and the severity of the acute attack. The fact that the severity of the disease increased with age, and that other age-related factors also contributed to a high fatality rate in the aged again emphasizes the desirability of definitive surgical treatment of cholelithiasis and cholecystitis in the individual at an earlier age.

Serious complications of empyema, gangrene, perforation, and peritonitis were prone to occur, particularly if surgical treatment was delayed. The case fatality rate in patients seen more than 72 hours after onset was apparently significantly greater than that in cases seen earlier. Careful analysis of the deaths revealed that 50% might have been prevented had surgery been employed earlier in the course of the disease.—Paul T. DeCamp, M.D., and others, Timing in the Surgical Treatment of Acute Cholecystitis, *Annals of Surgery*, May, 1952.

CLINICAL NOTES

GASTRIC HODGKIN'S DISEASE

W. Ross Morris, M.D., Washington, D. C.

Hodgkin's disease is one of unknown causation. It is a disease of lymphoid tissues usually affecting the lymph nodes primarily; it also involves the spleen, liver, and, in varying degrees, the lymphatic and reticular structure of almost any organ of the body. It may occur at any age, although it is rare in infancy and old age. In Hodgkin's disease the stomach is involved only infrequently; however, cases have been reported in which the disease was thought to have its origin in the stomach. Such a case may be the so-called isolated gastric Hodgkin's disease, in which there is apparently no involvement other than in the stomach. This is rare indeed. There may be gastric involvement secondary to involvement elsewhere, as in the spleen. Although this is rare it is encountered more frequently than the isolated form. Such a case is reported in this paper with a consideration of the best form of treatment.

REPORT OF A CASE

A white American housewife, aged 71, entered Doctors Hospital on Aug. 4, 1950. On admission she complained of weakness, nervousness, depression, shortness of breath, anorexia, and loss of weight. The patient had a history of marked anemia of seven or eight years duration despite dietary treatment, supplemented by vitamins, injections of liver and iron, and several transfusions. The anemia was very severe at times. After a careful study, including a negative roentgenographic examination of the gastrointestinal tract, a tentative diagnosis of pernicious anemia had been made.

Physical Examination.—The patient had a pale, warm, and moist skin. The blood pressure was 146/86 mm. Hg, the pulse rate 96, and the temperature 98.6 F. There was moderate generalized arteriosclerosis. Examination of the mouth showed upper and lower plates, and the tongue appeared redder than normal. There was a well-healed scar from a thyroidectomy and a well-healed scar from a left simple mastectomy. A grade 2 systolic murmur was heard over the pericardium, but it was not transmitted. There was slight tenderness on deep epigastric pressure, but no abdominal organs or masses were palpable. There was a shortening and slight atrophy of the left leg and a limitation of motion of the left hip. No glandular adenopathy was found.

Laboratory Examination.—Blood studies on Aug. 5, 1950, showed a white blood cell count of 17,500 per cubic millimeter: differential count, young forms 2%, band forms 3%, segmented forms 78%, neutrophils 83%, eosinophils 1%, basophils 0, monocytes 0, and lymphocytes 16%; red blood cell count 2,400,000 per cubic millimeter; and hemoglobin of 6 gm. (spectrophotometer method). The urine was normal. A roentgenographic examination of the gastrointestinal tract made several months previously revealed no pathological condition except a diverticulum of the second portion of the duodenum. A roentgenographic examination of the gastrointestinal tract made on Aug. 5, 1950 showed an ulcerative lesion 5 × 10 cm. on the greater curvatur side of the pars media. This was thought to be a large malignan growth, probably of the lymphoblastoma group. The diverticulu of the second portion of the duodenum was still present. In th gastric analysis the fasting specimen showed no free hydrochlori acid. There was no free hydrochloric acid after histamine a ministration.

From the Doctors Hospital.

A transfusion of 500 cc. of whole blood was given daily for three days. The patient improved greatly, and a blood test showed the hemoglobin to be 56% and the red blood cell count 3,010,000 per cubic millimeter.

Operation.—On Aug. 9, 1950, the abdomen was explored through an upper left paramedian incision converted into a T incision. The gallbladder was chronically inflamed and filled with stones. Along the lesser curvature and posterior wall of the stomach, about the middle third, there was a large ulcerated lesion, which appeared to be malignant; it was about twice the size of a silver dollar. There was no evidence of metastasis in the liver, but the glands in the gastrocolic and gastrohepatic omentum and around the celiac axis were enlarged and apparently metastatically involved. The spleen was very large (about the size of a small football) and contained large nodules, particularly on its posterior and superior surfaces where it was adherent to the peritoneum and the diaphragm. A subtotal gastrectomy and gastrojejunostomy (anterior Polya type) were done, with the removal of all the omentum, the gastrohepatic ligament, and the spleen. In doing the splenectomy it was necessary to remove a portion of the lateral part of the left diaphragm. After the lung was inflated by the anesthetist the opening in the diaphragm was closed. All involved tissue appeared to be removed except for the glands around the celiac axis. The wound was closed in layers around a drain placed in the splenic bed. The pathological examination revealed a malignant lymphoma, Hodgkin's type. The tumor appeared to be primary in the spleen with involvement of the stomach and regional lymph nodes.

Postoperative Course.—The patient had an unusually favorable postoperative course and was discharged from the hospital in good condition. She had gained weight and was eating well. A blood examination showed a white blood cell count of 11,300 per cubic millimeter: differential count, young forms 0, band forms 5%, segmented forms 84%, neutrophils 89%, eosinophils 0, basophils 0, monocytes 0, and lymphocytes 11%; red blood cell count 4,300,000 per cubic millimeter; and hemoglobin 13 gm.

Approximately three weeks postoperatively the patient was given a course of roentgen ray therapy (2,000 r) in an effort to destroy the glands that had been left in the region of the celiac axis. This produced marked radiation sickness evidenced by anorexia, nausea, loss of weight, and decrease in the blood cell count. She recovered gradually from this and continued in fairly good condition until January, 1951 (approximately five months postoperatively). At this time increasing weakness, loss of weight, enlarged glands in the left axilla and left cervical region, a left pleural effusion, and anemia developed. On Jan. 3, 1951, a blood examination showed a red blood cell count of 3,200,000 per cubic millimeter: differential count, young forms 1%, band forms 3%, segmented forms 80%, neutrophils 84%, eosinophils 1%, monocytes 2%, and lymphocytes 13%; white blood cell count 13,400; and hemoglobin 10 gm. Despite nitrogen mustard therapy, blood transfusions, removal of fluid from the left chest, and other procedures, the patient's progress was gradually downhill. On May 11, 1951, the patient was transferred to the Marine Hospital in Baltimore, where she died in June, 1951, from generalized Hodgkin's disease.

REVIEW OF THE LITERATURE

A review of the literature on gastric Hodgkin's disease revealed this to be a rare manifestation of the disease, whether it be found only in the stomach (so-called isolated Hodgkin's disease of the stomach) or whether it be gastric involvement secondary to involvement of the spleen or elsewhere. A clinical entity characterized by involvement of the glandular system, spleen, and, at times, other organs was first described by Thomas Hodgkin [1] in 1832. Since that time much has been learned about the disease; however, its cause remains unknown. There is no specific cure, nor even a satisfactory palliative treatment, known. In 1913 Schlagenhaufer [2] reported the first case of Hodgkin's disease in which the specific lesion was found in the stomach. Mead,[3] in a review of 16,254 autopsies, found only 3 cases of isolated involvement of the gastrointestinal tract. In a study of 212 cases of Hodgkin's disease Goldman [4] found the stomach to be involved in only 1 case. In a review of 54 cases of Hodgkin's disease Burger and Lehman [5] found only 2 cases with stomach involvement. Jackson and Parker [6] reported 3 cases of gastric involvement in a study of 174 cases. Goldman and Victor [7] reported only 1 case of gastric Hodgkin's disease in a series of 319 cases. In a review of 18 cases of the disease seen at Doctors Hospital, Washington, D. C., there were no cases of Hodgkin's disease of the stomach. These cases were diagnosed by postmortem examination, biopsy of a gland, or roentgenographic examination.

SYMPTOMATOLOGY AND DIAGNOSIS

The symptomatology of abdominal Hodgkin's disease is indefinite, varied, and bizarre. There may be present in varying degree any one or several of the following symptoms: anorexia, abdominal pain, nausea, constipation, hematemesis, persistent occult blood in the stools, fever, diarrhea, secondary anemia, leukopenia, and cachexia. There are no pathognomonic symptoms. Hayden and Apfelback [8] classified the symptoms in three groups: (1) ulcerative enteritis and colitis, (2) gastric carcinoma, and (3) intestinal obstruction. Primary anemia might also be added. Bockus [9] stated that a syndrome similar to that of duodenal ulcer has been reported in several cases. In this case the patient presented symptoms indicative of pernicious anemia for some time; finally the picture became that of a gastric malignancy.

ROENTGENOGRAPHIC STUDY

In cases of Hodgkin's disease of the stomach the roentgenographic findings have usually been interpreted as being indicative of carcinoma and, less frequently, of ulcer. Jungmann [10] and others, however, have emphasized a characteristic roentgenographic finding: persistence of peristalsis, even though sluggish, despite extensive involvement of the mucosa of the stomach. Now the correct diagnosis is made frequently by the roentgenologist from the roentgenographic appearance alone. In this case the roentgenologist stated that the gastric lesion had the appearance of a "very large malignancy of the lymphoblastoma group." The diagnosis of Hodgkin's disease of the stomach, however, is difficult and is usually not made before operation or necropsy. A final absolute diagnosis can be made only on histological section; there is no distinct clinical picture.

TREATMENT

As has been stated previously, Hodgkin's disease is usually a generalized disease; an occasional case reveals a pathological condition that is confined largely to the stomach. Cases have been reported in which postmortem examination confirmed the gastric limitation of the disease. In some of these cases perigastric node involvement or extension into the pancreas, or both, is found. It may be very difficult to demonstrate the extragastric lesion at operation. For these reasons an attempt to cure or prolong life by surgical intervention may be thought to be contraindicated. At present there is no satisfactory treatment known for this disease. The use of roentgen ray therapy, the use of nitrogen mustard, or the use of these two methods combined give palliative results in some cases; however, the use of these methods does not result in a cure, and they are especially ineffective in cases having gastric involvement. It should be remembered that generalized Hodgkin's disease may be asymptomatic for many years, while involvement of the stomach may result in death long before this would have occurred otherwise. This disease in the stomach causes loss of appetite, digestive disturbance, and loss of blood; these conditions speed the downward progress of the patient. Gastric resection, even though it is not curative, relieves these symptoms, makes the patient more comfortable, and prolongs life; I believe surgery is indicated and justified.

A review of the literature revealed approximately 43 cases of gastric Hodgkin's disease in which the patient was treated by surgical excision; perigastric node involvement was not found in all cases. A few patients died in the immediate postoperative period, and the survival time in the majority of cases varied from 5 months to 13 years.

Marshall and Brown[11] made a study of 406 patients who had been operated on at the Lahey Clinic from 1941 to 1945 for malignant disease of the stomach. They found that 16 patients (4% of the group) had noncarcinomatous malignant disease of the stomach, and 14 patients (3.4%), or 1 in every 30 cases, had malignant lymphomas; of these there were 8 cases of the localized form of gastric Hodgkin's disease. They came to these conclusions. 1. Malignant tumors of the stomach were relatively frequent. 2. The prognosis for patients with malignant lymphomatous tumors of the stomach was probably better than that for patients with gastric carcinoma. 3. Treatment should be radical surgery, as it is impossible to make a definite diagnosis of a lymphoid tumor before operation. Radiation therapy should be recommended following resection and should be recommended for those cases diagnosed inoperable after a laparotomy and biopsy. 4. A biopsy should always be obtained for definite identification of malignant gastric tumors considered inoperable at laparotomy, since there have been long-term survivals reported for patients with tumors of the lymphoma group following radiation therapy alone.

In 1950 Sandick[12] reported five cases of gastric Hodgkin's disease and reviewed the literature. He found only two cases in which postmortem examination confirmed the absolute limitation of the disease to the stomach. In our patient the Hodgkin's disease of the stomach was secondary to the splenic involvement, and there was no further evidence of disease except in the perigastric nodes. A subtotal gastric resection, excision of regional nodes, and a splenectomy were done. No similar case was found in the literature.

SUMMARY AND CONCLUSIONS

The literature on gastric Hodgkin's disease is reviewed briefly. There are no diagnostic symptoms. Roentgen findings may be quite indicative. A patient with Hodgkin's disease with gastric involvement treated by subtotal gastric resection is reported on. It is suggested that Hodgkin's disease of the stomach should be treated as any other gastric malignant disease: by surgical extirpation.

The case reported in this paper illustrates further that Hodgkin's disease may involve the stomach. When located in this area, it may be an isolated gastric Hodgkin's lesion or it may be secondary to a primary involvement in the spleen or elsewhere. The patient's life may be prolonged greatly by surgical excision of the gastric lesion, any diseased glands, and the spleen, if necessary. Results from some of the cases reported indicate that a cure may even be obtained. Therefore, it appears that the treatment of choice in gastric Hodgkin's disease is surgical extirpation.

ABSENCE OF COMMON BILE DUCT

Allan E. Sachs, M.D., Seattle

Anomalies of the biliary ducts are a constant source of concern to physicians performing surgery in that area. Numerous variations in the position and length of the cystic duct as well as the cystic artery have been described in detail. Mention has frequently been made of aberrant hepatocystic ducts; however, absence of the common bile duct, discussed in the following case report, has been reported briefly only once before, when it occurred in an infant who died because of this anomaly. The ducts were all atretic.[1]

This anatomic variation, if it had not been recognized in the usual technical performance of cholecystectomy, would surely have led to death or unfortunate complications. The maneuver emphasized by Gatch[2] of tracing the biliary ducts from within after emptying the gallbladder was helpful in tracing the anomaly. This procedure is a sound, valuable aid in preventing surgical accidents in the biliary ducts. I have seen no untoward complications resulting from this procedure, and I have been helped on several occasions in tracing ducts by probing from within.

REPORT OF A CASE

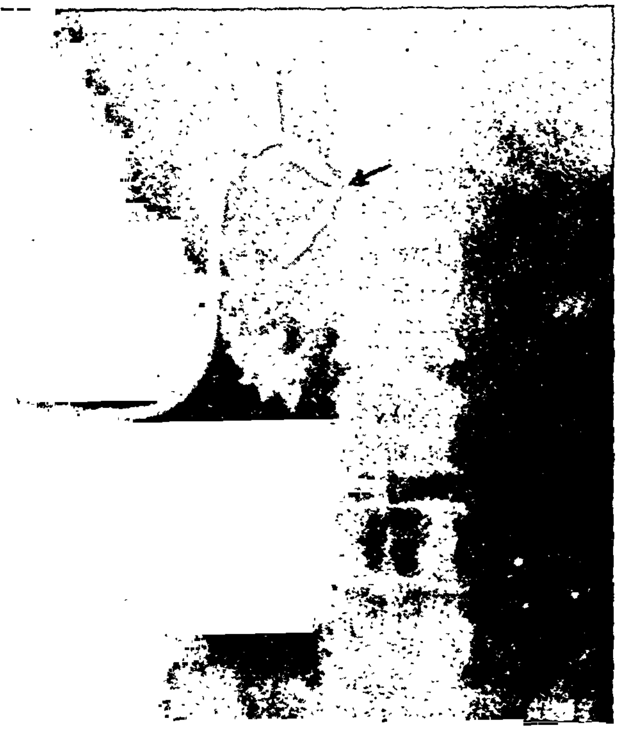
A 54-year-old schoolteacher was admitted to Group Health Hospital on Oct. 28, 1949, with the following history. Severe pain had developed in the right upper abdomen two days prior to admission. This was accompanied by nausea and one episode of vomiting. There was associated pain between the scapulas. At the onset, there had been diarrhea, but the stools then became clay-colored and floated on water. She noticed slight jaundice and pruritus. On questioning, it was learned that she had experienced pain of a milder nature during the last two years. Along with this, she had flatulence and constipation. Gallbladder disease had been suspected two years before, and, at that time, a Graham test showed no concentration of dye.

Physical examination revealed a well-developed, somewhat obese, white woman. Her temperature was 99 F orally, her pulse rate 76, and her blood pressure 124/80 mm. Hg. Positive findings included a slight icterus of the skin and conjunctiva. There was slight right upper abdominal tenderness but no rigidity. Laboratory tests revealed an acid urine with 50 mg. per liter of albumin; urobilinogen was 1:20; the white blood cell count was 8,900, with normal differential count; and the sedimentation rate was 22 mm. per hour. The total protein level was 5.8 mg. per 100 cc.; the albumin was 3.8 mg. per 100 cc.; the globulin was 2.0 mg. per 100 cc.; the serum bilirubin was 6.3 mg. per 100 cc.; the serum alkaline phosphatase was 21.5 King units; and the cephalin flocculation was negative in 24 hours. The provisional diagnosis was chronic cholecystitis with cholelithiasis and choledocholithiasis.

On Nov. 1, 1949, after suitable preparation with fluids, glucose, and vitamin K, the patient was operated on. The anesthetic, a tetracaine (pontocaine®) hydrochloride-dextrose mixture, was administered intraspinally. A right paramedian incision was made, and the gallbladder was visualized. It was distended, and the walls were inflamed and contained areas of purulent infection. Stones could be palpated in the cystic duct. The cystic duct was dissected free, and the cystic artery was identified. An attempt was then made to visualize the common duct; however, the duct could not be found in its usual location, and the hepatic duct was also absent in the gastrohepatic ligament. On dissection, the portal vein and the hepatic artery were found. The cystic duct was then dissected toward the duodenum; it was not dilated and did not enter a common duct. In order to study the anatomy before clamping the cystic duct more accurately, the fundus of the gallbladder was opened. Bile, pus, and pigment stones were removed from the gallbladder. The empty gallbladder was then probed from within with a small catheter. The catheter passed through the cystic duct easily and continued into the duodenum; however, no hepatic ducts could be found traversing backward from the cystic duct to the liver. On further probing, two hepatic ducts were found entering the midportion of the gallbladder. These ducts could be easily probed retrograde into the right and left lobes of the liver.

In order to perform a cholecystectomy, a bile duct anastomosis would have had to be done in the presence of acute infection. It was therefore decided that it would be wiser to do a cholecystostomy after removing the gallstones. A catheter was sewed in the gallbladder with pursestring sutures and brought out through a stab wound. After the cholecystostomy, the patient made an uneventful recovery. The catheter drain functioned well. After three weeks, the bile drainage was clear, and a direct cholangiogram was done with iodized oil (lipiodol®). The roentgenogram showed the anomaly clearly. After this study was completed, the drain was removed, and the wound healed promptly. The patient has now been followed for two years, during which time she has been asymptomatic.

This case is of interest because it is a rare but important deviation from the normal anatomy. It is interesting to note that the jaundice was easily explained by stones blocking the cystic duct, which, in this patient, was also serving as a common duct. In reviewing the literature for similar conditions and embryology of the biliary tract, one finds that such an anomaly might be expected. The gallbladder develops as an evagination from the common duct, and it could carry the hepatic ducts out from the common duct. It is impossible to be sure whether this case represents an absence of the common bile duct per se or the absence of a common hepatic duct. In certain species of reptiles, in most birds, and in one mammal, a type of otter, Lutra vulgaris, a somewhat similar condition exists.[3] A hepatoenteric duct drains directly into the duodenum, and a hepatocystic duct drains directly into the gall bladder. The latter duct has no direct communication with the duodenum. This patient had two hepatocystic ducts, possibly, with no common hepatic duct.



Direct cholangiogram three weeks after operation; the iodized oil injected through the catheter reveals the gallbladder with the hepatic ducts entering its midportion. The arrow points to the cystic duct. A single duct leads from the cystic duct to the duodenum.

SUMMARY

1. An unusual but important anomaly of the biliary tract is discussed.
2. The value of tracing the biliary ducts from within the gallbladder lumen is reemphasized.

USE OF SILICONE OILS IN MAINTAINING SURGICAL INSTRUMENTS

Frank W. Crowe, M.D., Ann Arbor, Mich.

Since the introduction of the organosilicon products into industry in 1943, the potentialities of these compounds appear to be unlimited. Their more recent introduction into cutaneous medicine [1] suggests many uses for their water repellent and lubricating properties in general medicine and surgery.

The physical and chemical differences of the silicones and organic compounds are marked, because the silicones have a quartz-like skeleton consisting of alternating silicon and oxygen atoms rather than the carbon atom framework of the organic compounds.[2] The silicones are water repellent, superior lubricants, which are chemically and physiologically inert and show marked surface adhesiveness. Physical properties [3] are remarkable in that the freezing point for the 500 centistoke (viscosity) DC 200 fluid is –50 C (–58 F). The boiling point for this fluid is 200 C (392 F), and the viscosity-temperature coefficients (viscosity-temperature coefficient equals $1-\frac{\text{viscosity at 210 F}}{\text{viscosity at 100 F}}$) are in the range of 0.60 to 0.625, showing that there is little change in viscosity with elevation of temperature. Volatility is less than 2% after 48 hours at 200 C (392 F). There is no significant toxicity from the silicones in the amounts used in this study. They have been fed to laboratory test animals in doses as high as 2% of their body weight without discernable ill effects.[4]

It is the standard procedure in many hospitals for surgical instruments to be cleaned in warm, soapy water after each operation. After drying, the individual instrument is usually oiled with high-grade petroleum lubricating oil. The clean instruments are then boiled and wrapped in sterile covers or wrapped and autoclaved in preparation for the next surgical procedure. In either method, the protective lubricating film is reduced or destroyed by the moist heat, and the free action of the instrument is frequently either impaired or lost. Much valuable time is spent in repetitious oiling of instruments, and inferior results are often obtained.

During the initial work with silicote® (a petrolatum base ointment containing 30% of the 60,000 centistoke DC 200 silicone fluids) many possibilities for utilizing the repellent and lubricating properties were apparent to the investigators. Among these was the application of pure silicone oils to surgical instruments prior to boiling or autoclaving to insure free motion of the instrument after sterilization. Initial coating of the instruments by using 60,000 centistoke DC 200 silicone oils proved reasonably satisfactory to both the surgeon and the operating room nurses, but it was difficult to handle because of its high viscosity.[5] It did, however, show that the oiling of instruments could be reduced to every fourth or fifth boiling without impairing the efficiency of the instruments.

For the past three months a preparation called "surgicote," a mixture of silicone oils, has been used in the University Hospital operating rooms, in the Dermatology Out-Patient Clinic, and in the University of Michigan Student Health Service Dermatology Clinic on all surgical instruments. The nurses and aids cleaning the instruments, the physicians using them, and the central supply room that was responsible for their care all felt that there was a significant improvement in ease of care and efficiency of the instruments while this agent was being tested.

The procedure used in caring for all instruments was as follows. All old, rusted, or corroded instruments were first treated in a rust removing solution then washed and dried. A thin coat of the "surgicote" was applied with an applicator stick to the entire instrument, making sure that the joints or fulcrum had been coated with the oil. A cotton flannel rag was used to wipe off the excess and to insure even distribution over the instrument. New instruments were treated in this manner as soon as they were obtained. It was observed that the older instruments remained rust-free and showed no signs of corrosion when this agent was used. Both the old and new instruments showed a freedom of action even after the most vigorous sterilization. Cleaning time was appreciably reduced, and the instruments required less oiling, often going through three or four sterilizations without further oiling.

Barondes [6] has also found the silicone fluids ideal for instrument sterilization; however, he used the method suggested by Crowley and Ostrander,[7] in which the instruments are placed directly in the hot silicone oils for sterilization. Although Barondes points out that the loss of fluid caused by carry-out on the instruments is minimal, it is felt that such a procedure was more practica in the small office than in a hospital because of this flui loss.

SUMMARY

A new agent is described in the care of surgical i struments. This agent is principally a silicone oil and an effective lubricant and water repellent while bei inert chemically and physiologically. It is nontoxic to t tissues with which it might come in contact. The ti involved in the care of surgical instruments is reduc with this agent, and the efficiency of the instruments appreciably increased.

The "surgicote" used in this study was furnished by the Silicote Corporation, Oshkosh, Wis.

PERIODIC SIALORRHEA

REPORT OF A CASE

Hobart A. Reimann, M.D., Wynnewood, Pa.
and
John N. Lindquist, M.D., Philadelphia

Attention has been called elsewhere to an assortment of periodic disorders of unknown cause that recur at more or less regularly predictable short intervals, last for years, do not respond to therapy, and do not affect the patient's general health.[1] The disorders were classified according to their respective outstanding features: fever, abdominalgia, arthralgia, neutropenia, purpura, and edema. It was predicted that interest in the problem and further search would reveal other bizarre examples of periodic disorders to add to the list. The purpose of this paper is to describe such a case and to refer to reports of similar ones published elsewhere.

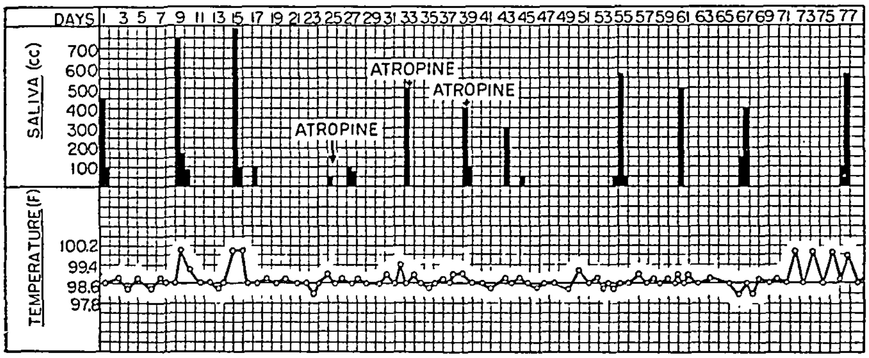
REPORT OF A CASE

Mrs. E. P., aged 44, had pain in her shoulders, arms, fingers, and toes in September, 1948. Her case was studied at a hospital, and a diagnosis of arthritis was made. Several teeth were extracted, against her protest, and excessive salivation was noted for one day. Thereafter, periods of salivation lasting a day occurred at about monthly intervals, until January, 1949, when the rest of her teeth were extracted. The intervals between the spells of salivation gradually shortened to 7 to 10 days. According to the patient's and her husband's statements, as much as 4 qt. (3,785 cc.) of saliva would be expectorated into a basin in a period of 24 to 36 hours. The flow was distressing, especially at night when saliva would flood over the pillow while the patient slept or the flow would keep her awake. She lost 50 lb. (22.7 kg.) during the next year, partly because of malnutrition owing to her inability to masticate. She has one son, aged 20, and has had four miscarriages. Her menstrual history is normal.

A study at another hospital made late in 1949 revealed she had hypotension, with 90 mm. Hg systolic and 60 mm. Hg diastolic pressure, and persistent eosinophilia of 23 to 44%. Polyarteritis, trichinosis, Addison's disease, rheumatoid arthritis, malnutrition, and sialorrhea were considered as diagnoses, but no conclusion was reached. Many consultations, special studies, and laboratory tests, including the Cutler-Powers-Wilder test, a Trichinella skin test, and roentgenographic examination, were all unrevealing. The patient's condition persisted, and in 1950, she came under our observation in the hospital for three months. Her chief complaints were spells of excessive salivation, occurring about once every week or 10 days and pains in her shoulders and calves, which became worse at night. Her intelligence was low, she was reticent and suspicious, and minor contradictions and inaccuracies were evident in the history she gave. Physical examination showed a normally developed, thin woman, 64 in. (162.6 cm.) in height and 123 lb. (55.8 kg.) in weight. Both submaxillary salivary glands were enlarged and palpable; the right was larger than the left, measuring about 3 by 4 cm. No evidence of arthritis could be seen in her roentgenograms. The muscles of her limbs were atrophic from self-induced inactivity. Psychiatric investigation revealed that the patient's childhood had been unhappy. Marriage at the age of 16 had caused more unhappiness. The patient is unkempt, and, since the onset of arthralgia in 1946, she has neglected housework, preferring to do nothing much of the time. Her outlook is severely restricted; she is hostile, dependent, and incapable of facing reality. She had made several visits to faith healers to obtain relief. Her response to examination and to questions indicated the existence of conversion hysteria. She complained of arthritis in the absence of objective evidence of the disease, while her other troubles were accepted passively. She refused to submit to an interview under narcosis. Her periodic bouts of salivation were thought by the psychiatrist to be psychically determined.

Results of laboratory studies were as follows: erythrocyte count, 4 million per cubic millimeter; hemoglobin, 12 gm. per 100 cc.; leukocyte count, between 7,000 and 9,000, with constant eosinophilia of 30 to 44%; the hyperplastic marrow contained many eosinophilic cells and their precursors; sedimentation rate, 29 mm. in 60 min. (Cutler method); basal metabolic rates, −27 and +4; the blood pressure varied from 80 to 130 mm. Hg systolic and from 40 to 80 mm. Hg diastolic; the pulse rate varied from 70 to 90 beats per minute. The temperature is shown in the figure. Roentgenograms revealed no abnormalities of the viscera and general demineralization of the bones. A sialogram showed a normal system of ducts in the submaxillary salivary glands and that the right gland was larger than the left. In an electroencephalographic examination done in a period between episodes of salivation, low voltage and abnormally fast activity were recorded, but no focal cerebral dysrhythmia was shown.

As shown in the figure, 11 episodes of sialorrhea were observed in 77 days, occurring at intervals of 4 to 12 days, the average being 7.6 days. The long periods after the 7th and 10th episodes indicate irregularities in the rhythm of recurrence, or that 2 episodes were skipped, or that inapparent episodes occurred in the regular rhythm of about 6 day intervals. The last possibility is suggested by slight rises in the patient's temperature that were evident on the 50th and 71st days. Similar fever accompanied or preceded most of the recorded episodes.



Schedule showing eleven periodic episodes of sialorrhea and fever in this patient. Note that atropine therapy greatly retarded the flow on one occasion.

An episode usually is preceded by a "scratchy sensation" of the eyes and a sense of fulness in the neck. The submaxillary glands, which are large, become larger, tender, and visibly swollen. Salivation begins abruptly and continues for 24 to 36 hours, occasionally ceasing for a period of several hours to a day and then resuming. Soreness in the mouth, headache, and pain in the chest are noted at times. As shown in the figure, the saliva collected in a container measured from 350 cc. to almost 1,000 cc. in different episodes. Much saliva was lost to measurement by swallowing and by drooling during sleep. The nocturnal flow is especially distressing to the patient. On inspection saliva could be seen welling in spurts from the sublingual ducts. Pressure on a swollen gland increased the flow. The secretion from the parotid glands seemed to be normal in amount. The fever that precedes or accompanies these episodes may be caused by the distention or overactivity of the glands, or, as in other periodic disorders, may be another aspect of the disorder. Occasionally, according to the patient, the prodromal symptoms mentioned may occur on time with slight or no salivation. During several episodes, slight vaginal bleeding was observed apart from four normal menstrual periods that took place during our study.

The patient left the hospital in August, 1950. Episodes continued unchanged, and she was induced to return in January, 1951, for a further study period of 53 days. Seven episodes of salivation were observed, spaced at intervals of 5 to 11 days (average 6.5 days). The largest amount of saliva collected in one period was 1,700 cc. and the smallest, 150 cc., but as before, much saliva was lost during sleep. The temperature, as in the previous study, rose slightly over 98.6 F during most of the episodes. All routine laboratory studies again gave normal results.

---

[1] Reimann, H. A.: Periodic Disease, Medicine **30**: 219-245, 1951.

Experimental Studies.—Because of the patient's suspiciousness, apprehension, and hostility to certain personnel, it was only with persuasion that she submitted to tests. Permission to perform biopsy of an affected gland was refused. It was desired to anesthetize the chorda tympani by injecting cocaine into the middle ear to observe the effect of eliminating stimuli over the parasympathetic nerves to the submaxillary and sublingual glands. The otic ganglion of the parotid gland could have been influenced by infiltrating the temporal fossa, or the effect of blocking the sympathetic nerve supply could have been observed by anesthesia of the superior cervical ganglion. These procedures were not permitted. The only suggestive evidence of an increased parasympathetic tone during the episodes were the accompanying slight rises in temperature. The pulse rate did not increase in frequency and the pupils did not change in diameter.

The saliva was mucinous and faintly opalescent. Its viscosity, measured with the Hess apparatus on many occasions during episodes and the intervals between them, varied within the normal range of 1.4 to 2.8 without relation to the amount. The pH varied from 6 to 7.7, usually tending toward greater alkalinity when the flow was copious. Measurements of the amount of amylase gave highly variable amounts from 600 to 80,000 units per 100 cc., the amount having no relation to the occurrence of the episodes. The amount of urea varied from 8 to 26 mg. per 100 cc. No eosinophilic cells were observed.

Four days after an episode the patient was given 10 mg. of pilocarpine hydrochloride by subcutaneous injection. Five minutes later salivation began and lasted 3 hours, a total of 200 cc. being secreted. An injection of isotonic solution of sodium chloride as a placebo failed to cause salivation. Pilocarpine hydrochloride injected during an episode apparently did not augment the flow. The flow stopped 10 minutes after 0.6 gm. of quinine sulfate was given orally during an episode and resumed in its usual volume after 4 hours. On another occasion, the same dose was given at three hour intervals with no effect. On one occasion, 50 mg. of methantheline (banthine®) bromide was given at 3 hour intervals after salivation had been in progress for several hours. Salivation was arrested after only 150 cc. of saliva had been collected. Seven days later, methantheline bromide given in similar amounts again apparently reduced the amount of saliva secreted to about 100 cc. The patient refused further therapy because the drug made her feel ill. The effect of atropine on the amount of saliva expelled is illustrated in the figure. The patient had eosinophilia of the blood and marrow as before, with 3,000 eosinophils per cubic millimeter. She was given an injection of 0.3 mg. of epinephrine, and 4 hours later the eosinophil count was 2,800 per cubic millimeter. On two occasions, the injection of 25 mg. of corticotropin failed to alter the count. Surgical removal of the affected glands or roentgenotherapy was suggested by consultants, but the patient refused further study and left the hospital.

COMMENT

Only one other reference to a nearly identical case of periodic sialorrhea was found in the literature; it was originally described in an inaccessible essay written by Emden in 1897.[2] It occurred in a woman, aged 54, who had, at first at long intervals and later regularly every eight days, bilateral swelling of the submaxillary and sublingual salivary glands. The swelling process would subside after three days, with expulsion from the salivary glands of fibrinous plugs and with profuse salivation. The possibility of a secretory neurosis was considered. Since 1879,[3] about 44 cases in adults and many in children of recurrent swelling of the parotid glands have been described.[4] Mention seldom was made of the submaxillary and sublingual glands. In many cases pyogenic infection, apparently caused by obstruction of the ducts, swelling of the glands, and secondary bacterial invasion, complicated the picture and interfered with clear-cut evidence of regular periodicity. Little attention was given to exact periodicity of glandular swelling, except for casual mention of recurrences in days, weeks, months, or two or three times a year over many years.[5] Sialorrhea was noted only in Vogeler's patient [6]; xerostomia was prominent in others. In one case, colic accompanied the glandular swellings.[7] The disorder was hereditary in a boy whose mother and grandmother had similar complaints.[8] Of Payne's 19 patients, 16 were women.[5b]

In cases described before 1935, infection was thought to be the cause, but later, as in other periodic disorders, allergy was suspected.[9] Of the 44 cases found in the literature by Bass, allergic manifestations were present in 12.[4] Bigler, however, saw no relation to allergy in his patients.[5c] According to Weber,[10] acute bouts of ptyalism are induced at times by gastrointestinal disturbances and muscular exercise. He suspected an allergic influence to be at fault, since persons so afflicted often have relatives who have allergic disorders. There seems to be no doubt that, at times, allergy may incite recurrent salivary disturbances. In some instances allergy or infection may serve as an inciting factor, but neither can account for uniform episodes of the disease regularly recurring for years without affecting the general health and resistance to therapy. Continuous sialorrhea occurred in a man, aged 50, two weeks after he received an injection of penicillin.[11] It was accompanied by urticaria, which vanished after six weeks during therapy with antihistaminic drugs, but the ptyalism continued. Ptyalism is a rare complication of pregnancy and is thought to be related to hyperemesis, which it may accompany.[12] Amounts as great as 2,000 cc. of saliva expelled in a day are recorded. Excessive salivation occurs in rabies, epilepsy, and other neurological disorders, particularly with lenticular involvement.[13] Normally, the amount of salivary flow varie greatly in different persons. In one study,[14] the amount secreted in a minute ranged from 0.08 cc. to 0.88 cc. Calculated at those rates the range for normal persons for a 24-hour period is from 115 cc. to 1,267 cc., an average of 345 cc.

[13] Furstenberg, A. C., and Crosby, E.: Disturbance of the Function of the Salivary Glands, Ann. Otol., Rhin. & Laryng. **54**: 243-264, 1945.

Whether the case of periodic sialorrhea we have described is of the same nature as the other reported cases of recurrent parotitis cannot be said. It probably is. Differences in glands affected and in the signs, symptoms, and behavior are understandable considering the complexity of the neurological control of the salivary glands as discussed in Furstenberg's paper.[13] In our patient and in others, additional convenient signs and symptoms suggest the presence of a systemic disturbance, with salivary disorder as the outstanding feature. Recurrent parotitis and periodic sialorrhea are similar to other periodic disorders in that they occur fairly regularly at short intervals, last many years without affecting the patient's general health, and resist therapy. The frequent occurrence of overlapping characteristics among other periodic disorders, suggesting a unity, is evident also in recurrent salivary disorders, in which abdominalgia, fever, eosinophilia, arthralgia, uterine bleeding, and evidence of hereditary transmission may be noted. Sialorrhea was observed in patients during episodes of periodic abdominalgia [15] and periodic neutropenia.[16] The cause of such disorders is unknown, but there is reason to suspect a common, underlying rhythm, which, in rare persons, provokes different symptoms and signs to recur in synchrony and which in the present case affects the salivary glands. Atropine and methantheline, at times, temporarily reduced the excessive flow of saliva, but tests with these drugs revealed no further hint as to the cause than those used in studies of other periodic disorders. The persistent eosinophilia of this patient may be inherent, but it was not present in her son. There was no evidence of allergy, polyarteritis, or other disease. The significance of the patient's abnormal electroencephalogram is undetermined.

SUMMARY

The occurrence of episodes of swelling of the submaxillary salivary glands with excessive salivation lasting a day or more and occurring at intervals of about 6 days for over 3 years in a 44-year-old woman is described. Studies failed to reveal the cause, and therapy, except for transient inhibition of the flow, was unsuccessful. Numerous cases of recurrent swelling of the parotid glands are on record. Because of their characteristic rhythmicity of recurrence over a long period and their lack of effect on the patient's general health, periodic sialorrhea and recurrent swelling of the parotid glands may belong to the group of diverse periodic disorders previously described.

CARCINOMATOUS MUCOSAL EXCRESCENCE OF THE RECTUM

Michael Weingarten, M.D.
and
Robert Turell, M.D., New York

There has been much discussion as to the pathogenesis of intestinal polyps and the possible evolution of benign adenomas into invasive carcinomas. No direct valid evidence of such a transformation has been offered, because of the necessity for complete removal of a lesion for microscopic examination to permit determination of its true histopathological character, thus rendering further study in situ impossible. However, considerable collateral evidence for malignant transformation is presented both on histological grounds, by Atwater and Bargen,[1] and on a clinical basis, by Helwig.[2] It is generally agreed that colonic polyps, if not already malignant, are potentially malignant and that, whenever observed, they should be extirpated, whether or not they are at the time producing symptoms. With regard to the smaller polyps, sometimes referred to as mucosal excrescences, there are, however, statements in the literature that tend to create a more complacent attitude. In many instances, these smaller lesions are either ignored or are fulgurated without being submitted for histological study, because their gross characteristics are considered unmistakably benign. Castro and co-workers [3] state that "on numerous occasions we have seen sessile mammilations 2 to 3 millimeters in size during routine proctoscopy. These are often gone when proctoscopy is repeated a few weeks later." In the light of such a statement, the following case is considered of interest.

REPORT OF A CASE

S. S., a 51-year-old white physician, while serving as a medical officer in the United States Army in December, 1943, began to experience fatigue and had an occasional loose bowel movement accompanied by slight discomfort in the lower part of the abdomen. He was admitted to a military hospital, where all his examinations yielded negative results except for the proctosigmoidoscopic findings. A "tiny polyp" was observed on the posterior wall of the rectum about 5 in. (12.5 cm.) from the anal orifice by a well-known and competent gastroenterologist. The patient was advised that there was no necessity for removal of this lesion, since it was so small, but that it should be observed periodically. In 1946, he had a recurrence of loose bowel movements and slight cramps for a short time but did not have further examinations until Feb. 17, 1950, when he consulted one of us (M. W.). The results of general physical examination, blood cell count, and urinalysis were normal. A warm, purged stool was negative for ova and parasites. Proctosigmoidoscopic examination was performed. The instrument was introduced for a distance of 10 in. (25 cm.). Five and one-half inches (about 14 cm.) from the anal verge, a small sessile polyp, about 2½ mm. in diameter, was seen. Its apex was raised about 1 mm. from the surface of the mucosa. The color was that of the surrounding mucosa, which appeared normal. When pressure was made with the rim of the sigmoidoscope against the surrounding rectal mucosa with the lesion held at the center, the polyp flattened out and became invisible. When the pressure of

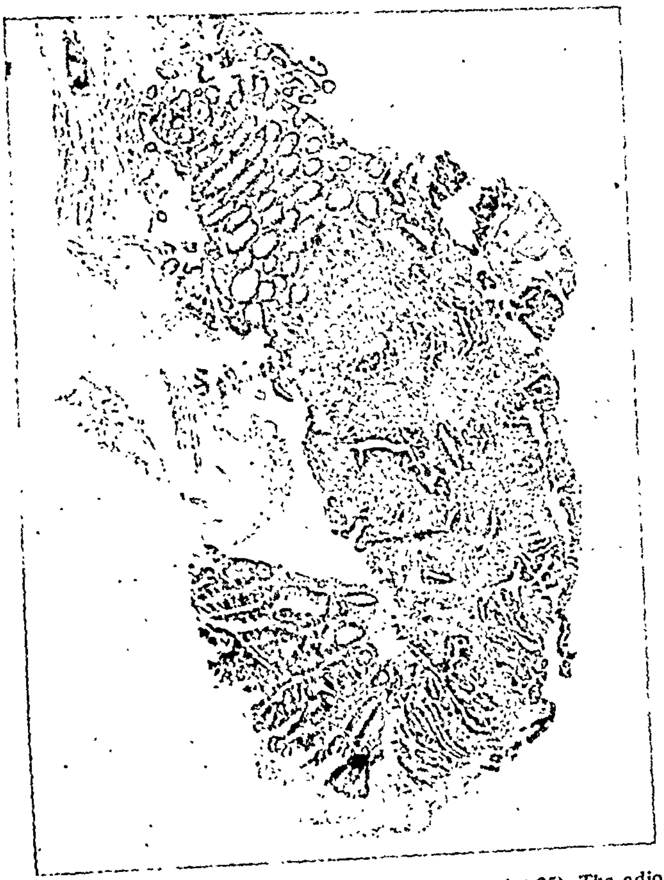
the instrument was released, it was apparent that a small polyp was present. The lesion was removed completely with a cold angulated, punch biopsy forceps and submitted for histological examination to Dr. William Antopol who reported that the specimen consisted of a fragment of soft gray tissue measuring 4 by 3 by 2 mm. Microscopic examination revealed normal glands at each end of the mucosal surface. The middle third of the mucosa was composed of glands that contained no mucous secretory glands. The acini had cells with scant cytoplasm and prominent nuclei. The nuclei were present at all levels, often reaching the free surface of the cell. Mitoses were frequent. These atypical glandular elements penetrated beyond the muscularis mucosae. In the region of the atypical glands there was erosion with numerous polymorphonuclear leukocytes. Because of the abnormal glandular pattern, the pronounced proliferation and the invasive tendency, the lesion was diagnosed as an adenocarcinoma.

The area from which the polyp was removed was fulgurated several days later by one of us (R. T.). Results of the barium enema examination of the colon, including air contrast study, were normal. The sigmoidoscopic examination has been repeated several times since, without evidence of recurrence. Results of a barium enema study done in May, 1951, were also normal.



Carcinomatous mucosal excrescence of the rectum (× 25). The adjoining mucosa is normal.

COMMENT

Mucosal excrescences seen on proctosigmoidoscopic examination are sometimes considered as being of no consequence or else are fulgurated thoroughly without biopsy, either to save the patient the cost of an additional laboratory procedure or because the observer feels confident that the gross appearance indicates that the lesion is benign. The foregoing experience with an excrescence of the rectum of less than 3 mm. in diameter, which proved to be an adenocarcinoma, emphasizes the necessity of submitting any accessible abnormal protrusions of the rectal or sigmoidal mucosa for histological indentification. One of us (R. T.), while experimenting with the construction of a cold, angulated biopsy forceps in 1940, removed a grossly benign-appearing mucosal elevation that was less than 2 mm. in diameter and which proved to be an adenocarcinoma on microscopic examination.[4] Hines and Riddler [5] recently reported the removal with a biopsy forceps of a sessile, submucosal nodule measuring 3 mm. in diameter from the anterior rectal wall, 4 cm. above the dentate line. Histological examination disclosed the nodule to be a carcinoid tumor. It is apparent that one cannot assume on the basis of the gross appearance or the small size of a mucosal excrescence that it is innocuous.

An interesting aspect of the case herein reported is that the description and location of the lesion as stated in December, 1943, corresponded with that observed in February, 1950. Although one cannot be certain, it would appear that we were dealing with the same "tiny polyp." It seems highly improbable that the lesion when first observed was carcinomatous in nature, since one would then have to assume that it remained dormant for six years and did not increase in size. In all likelihood, this mucosal excrescence was a benign adenoma, when it was seen in December, 1943, and underwent malignant changes shortly before it was removed. One may therefore state that in all probability this is an instance in which a benign adenoma of the rectum was observed and left in situ and became carcinomatous approximately six years later. Added weight is thus given to the generally held opinion that all abnormal protrusions of the rectosigmoidal mucosa should be completely removed when observed and submitted for histological examination.

SUMMARY

A case is reported in which a 2.5 mm. mucosal excrescence of the rectum, which had been observed six years earlier, proved to be carcinomatous in nature. The importance of removing and examining histologically every abnormal protrusion from mucosa of the instrumentally accessible terminal portion of the colon, no matter how small or innocent in appearance, is emphasized.

Wet X-Ray Films.—It is the practice for some people to make a habit of asking to see wet [x-ray] films, before the processing is completed by drying. This seems to be an opportune moment to point out that this procedure lays one open to making many errors. When a film is taken it is dry. When it is processed, the emulsion, including the layers of sensitized material, of which there may be 2 or more, swells up to between 4 and 8 times its original thickness. This swollen emulsion is particularly susceptible to physical damage from contact with other materials. What is, perhaps, more important, is that when there is any slight irregularity of the coating—even though this may not be sufficient to affect its photographic qualities—during the swelling the images formed become distorted and indistinct. It is therefore frequently impossible to detect minor alterations of structure, particularly in the study of bone trabeculation, until the film has been dried and the emulsion has returned to the physical state in which it existed when the film was exposed. Neither knowledge nor experience can overcome this physical deficiency in the images on a wet film.—Anthony A. Vickers, F.F.R., A Dissertation on X-Ray Diagnosis, *The British Journal of Physical Medicine,* May, 1952.

TOPICAL CHLORAMPHENICOL (CHLOROMYCETIN®) THERAPY OF PYOGENIC DERMATOSES

Capt. E. Randolph Trice (MC)
United States Army, Washington, D. C.
and
June Carol Shafer, M.D., Arlington, Va.

The continuing search for more effective agents for the treatment of pyogenic infections of the skin has led to the development of many improved preparations over the past few years.[1] In the evaluation of a new agent, two basic factors must be observed. The agent must possess an active bacteriostatic effect, preferably in low concentrations, against a wide spectrum of microorganisms that commonly affect the skin. It must also show a low index of cutaneous sensitivity. Some of the newer antibiotic ointments appear to meet both of these criteria.[1] Another factor worthy of consideration is the stability of the preparation in various vehicles. This report evaluates topical chloramphenicol with reference to effectiveness in the treatment of pyodermas, to cutaneous allergenicity, and to applicability in a greaseless base.

HISTORICAL DATA

In 1947, Ehrlich and co-workers[2] announced the recovery of a new antibiotic, chloramphenicol (chloromycetin®), from Streptomyces venezuelae after a tedious search of thousands of soil samples from all over the world. In vitro testing by McLean and co-workers[3] revealed a wide spectrum of susceptibility to the antibiotic by microorganisms commonly invading the skin, including Staphylococcus, Streptococcus, Aerobacter, Bacillus, Corynebacterium, Hemophilus, and other bacteria, certain spirochetes and Protozoa, fungi of the Actinomyces group, and some of the rickettsias and large viruses.

Recently, Cornbleet and Schorr[4] reported the results of topical chloramphenicol therapy in 18 cases of "eczema and pruritus of the ear canal," associated with bacterial infection in some cases. They used an ointment containing 0.275 gm. of chloramphenicol in 30 gm. of polyethylene glycol (carbowax 1500®). Initially, there was improvement in 16 of the 18 patients treated, but recurrences were frequent in those patients reached for follow-up inquiry. There was no instance of sensitivity to the preparation in the series. More favorable results were recorded by Newman and Feldman[5] in the treatment of 51 patients with various pyogenic dermatoses. They used a 1% chloramphenicol cream (0.300 gm. of chloramphenicol in 30 gm. of oil-in-water emulsion).[6] In patients with superficial pyodermas, there was rapid recovery, but less dramatic improvement was noted in patients with deeper infections. An additional 75 patients were treated later with the cream, and one instance of hypersensitivity was encountered.

ALLERGENICITY

For this report, patch tests of 2% chloramphenicol cream (0.600 gm. of chloramphenicol in 30 gm. of base)[6] were applied to 100 consecutive patients admitted to the dermatology section, Walter Reed Army Hospital. A total of 50 persons were retested 14 days later. There were no positive reactions from either the original or provocative tests. Of the treated patients, one showed a flare-up of the underlying dermatitis, but a patch test for chloramphenicol cream was negative.

Kerby and Muller[7] recently investigated a group of antibiotics, including chloramphenicol, with reference to the Shwartzman phenomenon. In their animal experiments, no hypersensitivity of the Shwartzman type was demonstrated. No cutaneous sensitivity was noted by Newman and Feldman[5] in 100 consecutive patients dressed with chloramphenicol cream after surgical procedures. As previously mentioned, one of their patients had a contact type of reaction. Patch tests were positive to chloramphenicol and negative to the cream base.

* Secondary infectious element cleared rapidly almost without exception.

CLINICAL MATERIAL AND RESULTS

A total of 100 patients with superficial and deep pyogenic infections from the outpatient clinic and inpatient service of the dermatology section of this hospital were selected for the study. Of this group, adequate follow-up examinations of 86 persons were available. The majority

of the patients were given a 2% chloramphenicol cream to be applied three times daily for from 3 to 14 days, depending on the severity of involvement. A few patients used a 1% cream, which, when applied more frequently, appeared to be as effective as the 2% preparation. Some patients in the series received nonspecific supportive measures, such as aluminum subacetate compresses and disinfection of shaving instruments.

Results of therapy with chloramphenicol cream are briefly summarized in the accompanying table. In general, there was clearing of most superficial infections within 3 to 10 days. In the group of patients with otitis externa, the underlying dermatitis remained in most instances, so that the final result was recorded as "improved." Chloramphenicol was effective, however, in clearing and preventing secondary bacterial infection. Deeper infections showed favorable results when treated early in the acute phase. In other chronic cases, chloramphenicol was no more effective than other antiseptic preparations.

COMMENT

In this series, chloramphenicol cream was found to be as effective in the therapy of pyodermas as other topical antibiotic preparations previously evaluated at this hospital, such as bacitracin[1c] and aureomycin.[8] These results are not so impressive as those reported by Newman and Feldman.[5] Perhaps this can be explained by the fact that the pyodermatous infections in patients referred to an Army general hospital have frequently reached a chronic stage and have been relatively resistant to ordinary treatment.

The oil-in-water emulsion base was particularly efficient as a vehicle for the drug for treating hairy and intertriginous areas. It was especially useful when applied before and after shaving by patients with recurrent folliculitis of the bearded area. Patients who had used ointment preparations previously found the cream base mechanically more suitable when used as a part of the shaving routine. Incorporation of 2% chloramphenicol in basic lotion[9] for patients with secondarily infected intertrigo (not included in this series) was also found to be efficient.

SUMMARY AND CONCLUSIONS

A wide spectrum of microorganisms that commonly cause pyogenic infections of the skin are susceptible to chloramphenicol. A total of 86 patients with superficial and deep pyodermas were treated with chloramphenicol cream. Favorable responses were noted in treating superficial infections. The response of deep pyodermas was no better than to some of the other topical antibiotic preparations. The oil-in-water emulsion base afforded an efficient vehicle for the drug in treating hairy and intertriginous areas. No proved instance of hypersensitivity developed in the patients treated. Patch tests in 100 persons and provocative tests in 50 of them failed to demonstrate an allergic response.

MECHANICAL AID FOR THE ARM AMPUTEE

Jerome Weiss, M.D.
and
Otto Eisert, M.D., Brooklyn

In recent years considerable advance has been made in the rehabilitation of the arm amputee by means of working prostheses. These are supplied with a prehensile hook operated by the opposite shoulder or by muscle motors produced surgically. For special purposes, modifications of the hook have been devised. Some prostheses provide for quick removal of the hook and replacement with a nonfunctioning hand for cosmetic effect.

These prosthetic devices have done much to restore the usefulness and to elevate the morale of the arm amputee; however, there remain two important functions that are still difficult for him. These are the opening of an ordinary can, and the removing or replacing of a bulky top from a jar. Dunton and Licht[1] recognize the difficulty that the usefulness of only one arm imposes. No present arm prosthesis that is useful for ordinary purposes will satisfactorily hold a can or jar unless modified in some way. The slipping of a can or jar can be dangerous, particularly for the one-armed amputee or hemiplegic who is using his good hand to do the work.

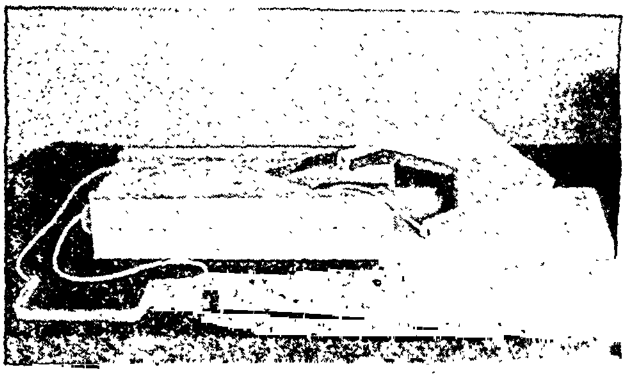

Fig. 1.—The holder with the movable jaw completely removed from its track. The stirrup appears at the left.

To make this chore safe and easy for the one-armed amputee or hemiplegic, a simple device has been developed by the physical medicine rehabilitation service of the Brooklyn Veterans Administration Hospital. It is an adaptation of the saddler's bench, in which foot power is used to clamp the leather and hold it while it is being stitched. Figures 1 and 2 are fully descriptive of the construction and use of the device.

Although many modifications in construction are possible, the device, as shown, is held to the simple form that can easily be produced in from three to four hours in the manual arts or occupational therapy departments of any good service of physical medicine and rehabilita-

From the Veterans Administration Hospital, Brooklyn.

Mr. William Conlon, manual arts therapist, constructed the mechanical aid from plans furnished by the authors.

Mr. F. Hertling, of the Medical Illustrations Section, Veterans Administration Hospital, Brooklyn, prepared the illustrations.

Reviewed in the Veterans Administration and published with the approval of the Chief Medical Director. The statements and conclusions published by the authors are the result of their own study and do not necessarily reflect the opinion or policy of the Veterans Administration.

[1] Dunton, W. R., and Licht, S., editors: Occupational Therapy: Principles and Practice, Springfield, Ill., Charles C Thomas, Publisher, 1950.

tion. The clamps and the extra length of the lower board are not required if the holder is screwed to the table top. The holding screws, if used, must be of the flat-headed type and must be countersunk below the top of the lower board. The addition of removable jaws to the fixed and moving members will make the device still more versatile. It will then approximate the saddler's bench and can be used to hold parts for soldering or for joining by other means.

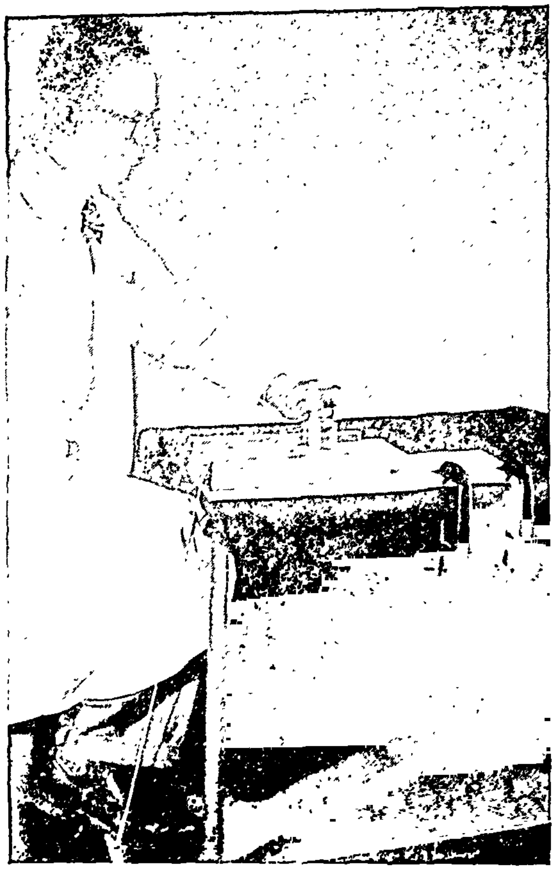

Fig. 2.—Here is demonstrated the use of the apparatus to facilitate the opening or closing of a jar by a one-armed person. The clamps are not needed if the holder is screwed to the table top.

The required materials, easily obtained, are given below:

Wooden boards—¾ in. plywood is excellent
Two small single awning pulleys—nonswivel type
About 5 ft. of strong awning cord
One 9 in. length of ⅛ or ¼ in. iron pipe
Two flat-headed iron wood screws—no. 8, 1 in. long
Three flat-headed iron wood screws—no. 10, 1½ in. long
Strips of rubber from an old innertube for the jaw faces
Two clamps, if the hold-down screws are not to be used

A 6 in. square sheet of rubber cut from an old innertube will improve the patient's grip on the jar cap or bottle top.

The amputee or hemiplegic will be able to use the holder perfectly after brief instruction, and, with a little practice, he will usually do better than an able-bodied person can without the holder. A simple device such as this can do much to help the arm amputee or the hemiplegic to attain independence.

MENINGITIS DUE TO KLEBSIELLA PNEUMONIAE

REPORT OF TWO CASES, WITH THE USE OF STREPTOKINASE AND STREPTODORNASE IN ONE CASE

Peter A. Trice, M.D.
and
Thomas E. Townsend, M.D., Fairfield, Ala.

In a recent article by Thompson and associates,[1] the rarity of meningitis due to Klebsiella pneumoniae was emphasized. These authors, in a comprehensive review of the literature, found only 118 cases, to which they added 1 case of their own. We wish to add two cases of meningitis due to K. pneumoniae diagnosed at the Lloyd Noland Hospital and to discuss the use of streptokinase and streptodornase in the management of one case.

REPORT OF CASES

Case 1.—I. F. B., a 2-year-old white girl, was admitted to the Lloyd Noland Hospital on Nov. 7, 1946, in a comatose state. The history revealed that the child had been well until the previous day, when fever with occasional vomiting developed. The child was examined by a local physician on the morning of admission. A diagnosis of "sore throat" was made and a sulfonamide drug prescribed. After taking approximately 0.5 gm. of the prescribed drug, she seemed much worse and was brought to the Lloyd Noland Emergency Clinic, where she was immediately admitted to the hospital. On admission, at 6:30 p. m., the child was comatose and cyanotic. The pulse was palpable in the legs and temples; the heart sounds were of poor quality and rapid. The right pupil was irregular and fixed to light. The left pupil was pinpoint sized. It was apparent that she was dying. She did not respond to supportive therapy and died an hour and 20 minutes after admission.

Autopsy revealed purulent meningitis and pneumonia. Sterile blood cultures and spinal fluid cultures done at autopsy revealed K. pneumoniae.

Case 2.—N. E. M., a Negro infant, was born prematurely at the Lloyd Noland Hospital Sept. 5, 1951. The delivery was sterile with spontaneous left occiput anterior presentation. The cry was weak and delayed; the lungs were not fully expanded; and slight cyanosis was present around the mouth. The birth weight was 4 lb. 2 oz. (1,871 gm.), and the length was 17½ in. (44 cm.). The infant was placed in an incubator with oxygen, and there was rapid improvement. He was removed to a bassinet on the second day. The weight gain was slow for the first five days, but after the caloric intake was increased the gain was satisfactory.

On Sept. 24, at 19 days of age, the infant became cyanotic and experienced some respiratory difficulty. The lungs were clear to auscultation; the heart rate was rapid, but the sounds were of good quality. He responded well to treatment with oxygen and a stimulant. The possibility of an intracranial hemorrhage or aspiration of formula was considered at that time. Immediately after this episode some spasticity of the extremities was noted. This was believed to be a result of anoxia and disappeared in approximately 24 hours. After this, the infant's condition remained good. He took his formula well, and the weight gain was satisfactory.

On Oct. 1, when the patient was 26 days of age, it was noted that the anterior fontanel was full but not tense. A lumbar puncture revealed xanthochromic fluid with 1,750 cells per cubic

---

From the Pediatric Department, Lloyd Noland Hospital.

[1] Thompson, A. J.; Williams, E. B., Jr.; Williams, E. D., and Anderson, J. M.: Klebsiella Pneumoniae Meningitis: Review of the Literature and Report of a Case with Bacteremia and Pneumonia, with Recovery, Arch. Int. Med. 89: 405-420 (March) 1952.

millimeter, 87% of which were neutrophils and 13% lymphocytes. The smear was negative. Treatment with dihydrostreptomycin, 0.25 gm. every eight hours, and penicillin, 100,000 units every three hours, was started. The following day spinal fluid culture revealed an organism resembling K. pneumoniae. At this time chloramphenicol therapy, 250 mg. every four hours, was started. On Oct. 3 the organism was definitely identified as K. pneumoniae. Tests revealed the organism was sensitive to chloramphenicol, streptomycin, and aureomycin, in the order named. On Oct. 4 the fontanel was tense and the general condition poor. The temperature at this time was 99.8 F per rectum, and at no time during the course of the illness was it any higher. The infant continued to take his formula well but required supplements of fluids, given parenterally. On Oct. 6 he had a generalized, clonic convulsion, which was controlled by sedation. On Oct. 10 a lumbar puncture was done, but no spinal fluid was obtained. A ventricular tap was therefore performed. The ventricular fluid revealed 1,250 cells per cubic millimeter, 90% neutrophils and 10% lymphocytes. Smear and culture were negative. The protein was 800 mg., sugar 16.9 mg., and chlorides 603.1 mg. per 100 cc. At this time a gradual increase in the circumference of the head was noted, with a tense and bulging fontanel. On Oct. 18, 20 cc. of xanthochromic fluid was obtained by ventricular tap, and 125,000 units of streptokinase and 25,000 units of streptodornase ("varidase")[2] diluted in 10 cc. of distilled water were instilled. The ventricular fluid contained 4,300 cells with 70% neutrophils, and 30% lymphocytes. Protein was 640 mg., chlorides 586 mg., and sugar 30 mg. per 100 cc. Smear and culture were negative. After this there was definite clinical improvement. The weight gain was steady; feedings were taken well; no fluids were required parenterally; there was no further increase in circumference of the head; and the fontanel returned to normal. Penicillin therapy was discontinued on Oct. 20 and streptomycin and chloramphenicol therapy on Oct. 24. On Nov. 7 a lumbar puncture for therapeutic evaluation was done. No fluid was obtained. Ventricular tap revealed 325 cells, 60% neutrophils and 40% lymphocytes. The protein was 164 mg., chlorides 659 mg., and sugar 32.5 mg. per 100 cc. Smear and culture were negative. Treatment was discontinued, and the infant was discharged to be followed in the outpatient clinic. At this time the infant weighed 5 lb. 15 oz. (2,693 gm.). The diagnoses on discharge were prematurity and meningitis due to K. pneumoniae, with acquired hydrocephalus. The follow-up on this patient was inadequate, owing to lack of cooperation by the family.

The patient was not seen again until readmission, Jan. 1, 1952, some 54 days after discharge. At this time he was 4 months of age. The mother stated that the child's head had suddenly become larger the night before admission but that he had been well until that time. However, physical examination revealed severe malnutrition, the weight being 7 lb. (3,175 gm.), and severe hydrocephalus. The respirations were 20 to 30 per minute and very shallow; the pulse was weak and the rate 60 per minute; and the temperature was 94.8 F per rectum. The infant appeared both acutely and chronically ill. Lumbar puncture was done on admission, but no fluid was obtained. Ventricular tap revealed 10 cells per cubic millimeter, all of which were lymphocytes, and protein was 435 mg. per 100 cc. Smear and culture were negative. Treatment with chloramphenicol, 250 mg. every four hours, and dihydrostreptomycin, 0.25 gm. every eight hours, was started. Supportive measures consisted of the use of plasma, fluids parenterally, oxygen, and heat. Ventricular taps were done on Jan. 3, 4, and 6, with instillation of 50,000 units of streptokinase and 10,000 units of streptodornase each time. After this, there was some improvement in the general condition and the fontanel became less tense. However, the circumference of the head steadily increased.

Ventricular taps were repeated on Jan. 16, 21, 22, and 23, with instillation each time of 87,500 units of streptokinase and 17,500 units of streptodornase. On Jan. 24, ventricular tap was performed, with instillation of 125,000 units of streptokinase and 25,000 units of streptodornase. All ventricular taps revealed normal cell counts, negative smear and culture, and an elevated protein level. After the last ventricular tap, it was felt that maximum benefit had been obtained from the streptokinase and streptodornase therapy and that further treatment with these agents was not indicated. The infant was removed from the hospital by the parents on Jan. 26, on the 26th day of his second hospital admission and 116 days from the time his illness was first diagnosed. The weight on discharge was 9 lb. (4,082.33 gm.), a gain of 2 lb. (907.18 gm.) during the last hospitalization. Follow-up was to be done through the outpatient clinic, with treatment to be reinstituted as indicated. Once again, cooperation on the part of the family was poor. The patient was not seen again and died at home on Feb. 12.

COMMENT

In case 1, the infant was moribund on admission and died an hour and 20 minutes after admission to the hospital. There was time for no treatment except supportive measures, to which the infant failed to respond. The diagnosis was made at autopsy.

In case 2, owing to our failure to obtain spinal fluid on repeated lumbar puncture, we felt that the flow of fluid into the spinal canal was probably obstructed by fibrinous exudate. Because of the favorable reports of the fibrinolytic effect of streptokinase and the hydrolytic effect of streptodornase,[3] it was hoped that these drugs would liquefy the fibrinous exudate. Cathie and MacFarlane[4] reported the use of streptokinase intrathecally in cases of tuberculous meningitis, with favorable results when used before organized exudate was formed. As noted in the case report, definite improvement followed the initial instillation of 125,000 units of streptokinase and 25,000 units of streptodornase. Prior to the use of these fibrinolytic agents, the anterior fontanel was consistently distended and there was gradual increase in the circumference of the head. After the first instillation of streptokinase and streptodornase, the fontanel remained soft and the circumference of the head remained the same. However, lumbar puncture was still not productive of spinal fluid. On the initial hospital admission only one ventricular tap was performed after the instillation of the agents (on the 20th day), and this was for follow-up study rather than for therapeutic purposes.

On the patient's readmission to the hospital, 54 days after discharge, there was pronounced distention of the anterior fontanel and hydrocephalus. It is regrettable that the patient had not returned to the clinic during this interval. Because of the apparent beneficial results obtained with the use of streptokinase and streptodornase on the first admission, it was felt that further treatmen with these agents was warranted. Benefit was minimal even with daily instillation. The patient was remove from the hospital against our advice, so that furthe observation was not possible. He died at home 16 day after leaving the hospital.

Since the infecting agent apparently was controlled b streptomycin and chloramphenicol therapy, as indicate by sterile cerebrospinal fluid on repeated cultures, it felt that death was due to the complications and not primarily to the infecting organism.

---

SUMMARY

Two cases of meningitis due to Klebsiella pneumoniae are reported. Sensitivity studies in case 2 indicated the organism was most sensitive to chloramphenicol. The meningitis was controlled by the use of chloramphenicol and streptomycin. The use of streptokinase and streptodornase in one case is discussed. It is felt that some benefit was obtained from the use of streptokinase and streptodornase. Further investigation of the use of these agents in cases of meningitis in which blocks to the circulating cerebrospinal fluid are developed would seem justified. No untoward results from the administration of the streptokinase and streptodornase were detected.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

APPARATUS ACCEPTED

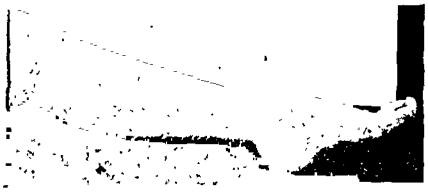
The following additional products have been accepted as conforming to the rules of the Council on Physical Medicine and Rehabilitation of the American Medical Association for inclusion in Apparatus Accepted. A copy of the rules on which the Council bases its action will be sent on application.

Ralph E. De Forest, M.D., *Secretary.*

The Jobst Stocking

Conrad Jobst, P. O. Box 653, Toledo, O.

The Jobst Stocking is intended for use in the treatment of circulatory disorders of the legs and differs from other available elastic stockings in the special arrangement for fitting the stocking to the individual patient's leg. This consists of a tape that automatically affords measurements of circumference at predetermined levels on the leg.



The Jobst Stocking.

The unpacked stocking weighs 70 to 90 gm. (2½ to 3 oz.). Its shipping weight is 78 to 98 gm. (2¾ to 3½ oz.).

Evidence obtained from sources acceptable to the Council indicated that The Jobst Stocking was well made and served the purposes for which it was designed. It was emphasized that elastic stockings are not suitable for all types of circulatory disease, that the physician, not the patient, must decide whether the stocking is needed in a given case, and that the measurements must be made by someone with experience and skill.

Bauer & Black Nylon Elastic Stockings, Models N-1 and S-1

Bauer & Black, Division of The Kendall Company, 309 W. Jackson Blvd., Chicago 6.

The two types of elastic stocking referred to in this report are made of a combination of nylon and elastic in such a way as to give a two-way stretch. The heel and the top are nonelastic, and the stocking is maintained in position by garters or a girdle support. Both are of a beige color, light in weight, and of sufficient strength for use in slight swellings and milder forms of edema.

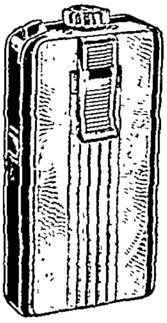
Evidence from sources acceptable to the Council showed that these stockings were well constructed. It is pointed out that elastic stockings can be effective in some forms of peripheral vascular disease, but injurious in others, and that the physician, not the patient, is the one to decide whether elastic stockings are advisable in any given case.

Sonotone Hearing Aid, Model 966

Sonotone Corporation, Elmsford, N. Y.

The Sonotone Hearing Aid, Model 966, is an electric hearing aid housed in a case of plastic and metal. The user may wear it with batteries or connect it to external batteries. With batteries it weighs 326 gm. and measures 2.6 by 6.8 by 12.5 cm.

Evidence from an acceptable source indicated that this instrument met the published requirements of the Council for hearing aids.



Sonotone Hearing Aid, Model 966

Monaghan Hospital Respirator, Model 110

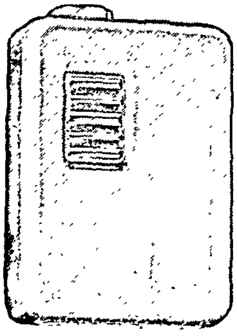
J. J. Monaghan Company, 500 Alcott St., Denver 4.

The Monaghan Hospital Respirator, Model 110, is a cuirass type respirator designed to supply the needs of two patients at once and also permit the administration of positive intratracheal pressure in time with the cycles of negative extrathoracic pressure.

The apparatus is housed in a large cabinet which stands on casters on the floor. Unpacked, it measures 94 (height) by 95 by 51 cm. (36½ by 37 by 20 in.) and weighs 66 kg. (145 lb.). The series of plastic shells (six shells of graduated sizes) are contained in one door of this cabinet; the positive pressure unit with other accessories are contained in the other. The cabinet also houses the pump and motor, which operates on 50 to 60 cycle alternating current at 110 volts and draws 130 watts.

Packed for shipment, the unit measures 107 by 101 by 62 cm. (41¾ by 39¼ by 24 in.) and weighs 94 kg. (206 lb.).

Evidence from sources acceptable to the Council showed that the device satisfied the published requirements of the Council for acceptance of respirators of the cuirass type as stated in The Journal, April 30, 1949, page 1273.



Telex Hearing Aid, Model 500

Telex Hearing Aid, Model 500

Telex, Inc., Telex Park, St. Paul 1.

The Telex Hearing Aid, Model 500, is a conventional electric hearing aid in shape and general design. It measures 61 by 44 by 21 mm. without clothing clips and weighs 82.5 gm. without batteries. The batteries weigh 25 gm., and the receiver and cord weigh 10 gm.

Evidence of good workmanship and satisfactory performance was obtained from a laboratory acceptable to the Council.

Dome-Paste Bandage

Dome Chemicals, Inc., 109 W. 64th St., New York 23.

The Dome-Paste Bandage consists of strips of impregnated gauze intended for application to the legs, as with Unna's Paste Boot, in the treatment of peripheral circulatory disease. Each strip, measuring 914 cm. (10 yards) in length and 10.2 cm. (4 in.) in width, is wrapped in wax paper and enclosed in a tin can. Twelve such bandages, separately packed, fill a multiple-unit container.

From acceptable sources the Council obtained evidence indicating that the Dome-Paste Bandage was convenient and efficient.

Dome-Paste Bandage

CORTISONE, CORTICOTROPIN, AND TUBERCULOSIS

Considerable uncertainty has arisen concerning the use of cortisone and corticotropin in the presence of suspected or proved tuberculous lesions. Sufficient evidence appears to have been accumulated to at least suggest caution in the use of these drugs in a patient with tuberculosis.

Two recent reports now reveal without any doubt the need for this conservative approach.[1] The Committee on Therapy of the American Trudeau Society and an associated committee, the Laboratory Subcommittee, have offered evidence that should be kept in mind when cortisone and corticotropin are used clinically. The latter committee, after examining 39 published papers and personal communications, concluded that, insofar as the data from studies on experimental tuberculous infections in animals are concerned, the drugs may produce a variety of effects, depending on the species of animal and the experimental conditions. The hormones produce a decrease in reactivity of the small blood vessels, which in turn reduces the inflammatory response of sensitized tissue to the tubercle bacillus. Cortisone can cause a flare-up of a tuberculosis infection in mice. When the hormones are withdrawn, a tuberculosis lesion may become more active. Further, the hormones have no significant action on the tubercle bacillus itself in vitro.

The Committee on Therapy analyzed data on 81 patients treated with cortisone and/or corticotropin in whom tuberculosis was present or became a complicating factor. Autopsies had been performed on many of the subjects. From their study the members of the committee concluded that an exacerbation of tuberculosis infection does not always follow use of cortisone or corticotropin, but that these drugs do have an effect on active and apparently inactive tuberculosis. For example, there often were found in their studies a spectacular dissemination of the disease and unsatisfactory localization of the lesions. They also report development and progression of excavation during and after the hormone therapy. Yet these drugs may cause signs of clinical and symptomatic improvement even as the lesions are becoming progressively worse.

Therefore, the Committee on Therapy has concluded that cortisone and corticotropin appear to have no place in the treatment of active tuberculosis as such, and in the presence of active tuberculosis infection the use of these drugs should be regarded as potentially hazardous. While the presence of old, apparently inactive, tuberculosis is not an absolute contraindication to therapy, the condition should be studied carefully; if one of the drugs is used, there should be frequent examinations of roentgenograms and the sputum. Even in the absence of known tuberculous infection there should be careful examinations before, during, and after therapy, as there may be exacerbation of an unsuspected lesion. If a pulmonary infiltrate develops during or after therapy with cortisone or corticotropin, the presence of tuberculosis should be suspected until it is proved otherwise. When these drugs must be used when a tuberculous infection is known to exist, it may be wise to employ at the same time antimicrobial agents such as streptomycin and para-aminosalicylic acid. The findings and conclusions of these two committees of the American Trudeau Society emphasize the need for caution when new drugs are employed.

RHODOPSIN

It has long been known that optimal function of the eye is associated with adequate nutrition, and, once the nutritive importance of vitamin A had been established, this food factor was shown to be involved in the photochemical cycle that is the physiological basis of sight. The retina is known to be extremely rich in vitamin A potency,[1] and it has been shown [2] that when visual purple, or rhodopsin, is acted on by light, a carotenoid yellow pigment (retinene) is formed, which, in turn, gives rise to vitamin A. In natural dark adaptation this process is reversed and rhodopsin is regenerated in the rods of the retina. In the course of the dissociation of rhodopsin, there is formed, in addition to the retinene, a protein called opsin. In recent reports [3] successful experiments are described in which rhodopsin has been synthetized from opsin and high concentrations of synthetic retinene; the resulting synthetic product was shown to be visual purple by physical and chemical tests, although the efficiency of the in vitro reaction does not approach that in the intact retina.

Further studies [4] of the circumstances attending the effect of light on rhodopsin have shown that the in vitro synthesis of this pigment can be accomplished when the retinene (vitamin A aldehyde) is prepared in the laboratory from fish liver oils but not when crystalline vitamin A is the source of the retinene. This observation has led to the conclusion that some cis-isomer of vitamin A rather than the trans- form is essential for the reformation of retinene. It appears that the principal action of light on retinene is to isomerize it rather than to decompose it. By further analysis of the response of retinene to various wavelengths of light, the conclusion has been reached that the retinene emerging from the bleaching of rhodopsin is a different isomer from that subsequently entering into the synthesis of the visual purple.

[4] Hubbard, R., and Wald, G.: Cis-Trans Isomers of Vitamin A and Retinene in Vision, Science **115**:60, 1952.

It becomes of considerable interest to determine the nature of the chemical bond between the protein (opsin) and the chromatophore (retinene) of the rhodopsin. In a recent report [5] experimental observations are described that throw light on this point. Although the aldehyde group of the retinene might be expected to combine with the amino groups of the protein, evidence is established to show that the retinene combines with opsin through the sulfhydryl groups of the latter. To further prove this point, it was shown that, in the course of bleaching of rhodopsin, reactive sulfhydryl groups appear in the system. Although these circumstances indicate that the bleaching of visual purple by light is similar to the well-known denaturation of proteins, the changes in rhodopsin during bleaching suggest that the structure of visual purple is more complex than reactions of the sulfhydryl group might indicate.

Despite the newer observations that a definite spacial relationship in the atoms of vitamin A is required for the synthesis of rhodopsin, the fact remains that the body has no other source of this indispensable factor than the food. The factor of safety lies in the fact that, when one isomer of vitamin A is fed, the liver soon contains a mixture of known isomers.

VACATIONS AND DIARRHEA

Each year, particularly in the summer and fall, physicians must treat patients with serious diarrheal disease resulting from vacation trips. Study of this problem for many years [1] shows there are three basic aspects, involving the layman, the family physician, and public health officials. The family physician is the most important link between the patient and public health department. Without him it would be impossible to carry out the epidemiological and bacteriological studies necessary for control. Since 1934 the Dysentery Registry has carried out educational campaigns each summer for laymen. The film, "From Hand to Mouth,"[2] has been in continuous use in schools, colleges, and hospitals both here and abroad since its first showing at the New York World's Fair.

Physicians have been alerted to the necessity for isolation and fecal cultures and recognition of new clinical forms of diarrheal disease. Public health agencies are now cognizant of the wide prevalance of infectious diarrhea and are making vigorous efforts for their control, and yet, to those interested in this field of medicine, these diseases seem to continue unabated. However, the reasons appear to be quite obvious. The average layman takes his vacation with little or no thought to the hygienic or sanitary conditions he is to encounter or with a feeling of helplessness over their control; he may not have the protection of a well-organized city health department; boiling the drinking water does not solve all the problems of infectious diarrhea; and dirty eating utensils, infected foodhandlers, unsanitary privies, and fly prevalence are very important but not so recognized by many travellers. Furthermore, the family physician sometimes is beset with the difficulty of differentiating the causes of the diarrhea without bacteriological help. He is often troubled by the reluctance of the patient or family to have the case reported, to have feces cultured, or even to carry out simple isolation procedures. Health departments are hampered by failure to report cases of diarrheal diseases and by lack of personnel to inspect summer hotels, camps, and restaurants. Many resort areas have seasonal overloads and water supplies and sewage disposal systems that may be adequate for the normal low population level become inadequate.

The enormity of the problem may be ascertained from recent figures.[3] In 1951, more than 72 million Americans took 25 million vacation trips, and it was estimated that the tourist pleasure industry involved an annual expenditure of 7 to 10 billion dollars. There are 42,800,000 passenger cars, and trailer coach manufacturers produced 67,335 trailers in 1951. In the same year the National Park System had 36,679,316 visitors. Today there are more than 30,000 motels and 15,000 hotels in the United States, all of which encourages Americans to travel.

Modern advances in the control of diarrheal disorders have been due to a correlation of increased knowledge of the clinical, pathological, and bacteriological aspects. In the Shigella and Salmonella diseases early and repeated sigmoidoscopic studies have revealed as much or more than examinations at necropsy. For example, it has been demonstrated that patients with Shigella disease (bacillary dysentery) due to contact often have no clinical complaints yet have the characteristic one, two, or three stage pathological changes in the colon. The practical implication is that the feces of all persons who have had contact with Shigella disease must be cultured whether the persons have symptoms or not.

The diarrheal disease known as chronic ulcerative colitis remains one of the most difficult problems in medicine. Much of the literature appears to be controversial. There is no doubt, however, that in some instances the disease follows acute bacillary dysentery,[1] as shown by serial sigmoidoscopic studies carried out in the same person from the initial acute specific phase to the fully developed chronic form. Even a possibility of lessening the frequency of this one disease by preventing bacillary dysentery and other acute infectious diarrheas warrants careful study of the control of diarrheal disorders.

AMERICAN LEGION PHYSICIANS

Members of the American Medical Association who are planning to attend the American Legion Convention in New York City are invited to visit the rooms that will be reserved for the Association at the Statler Hotel from Aug. 24 to 27. Several individuals from the headquarters staff will be present to receive A. M. A. members.

MEDICAL NEWS

ALABAMA

Diagnostic Poliomyelitis Screening.—Through its consulting committee, the Montgomery County Health Department is prepared to render community service in the event of a poliomyelitis epidemic. The committee is composed of pediatricians, pediatric surgeons, and an orthopedist appointed by the county health department each year to serve during the poliomyelitis season. Two physicians, including one member of the consultant group, are required to see each patient under observation. Consultant service is without charge, regardless of the patient's ability to pay. Confirmed poliomyelitis cases must be reported to the county health department; however, physicians are asked to report suspected cases so that the health department may be alerted for possible emergency care of such cases. Except in extreme cases with paralytic or bulbar involvement, hospitalization of poliomyelitis and suspect cases is discouraged. A physical therapist employed by the county health department and paid by poliomyelitis funds provides home care to patients in Montgomery County and seven adjacent counties.

CONNECTICUT

Clinical Congress at New Haven.—The Connecticut Clinical Congress of the Connecticut State Medical Society and the Yale University School of Medicine will be held at New Haven Hospital and the Yale School of Medicine, New Haven, Sept. 17 and 18. Three sessions will be held simultaneously in three different meeting places, giving a broad selection of topics. Discussions on Wednesday include diabetic coma, arthritis, toxemias of pregnancy, gout, hyperthyroidism, arteriosclerosis, causes of sudden death, and new therapeutic agents in tuberculosis and hypertension. At 3:30 p. m. there will be a pediatric seminar on "Abdominal Pain in Infancy and Childhood," "Anemias in Childhood," and "Renal Diseases in Children." Other presentations will include "Progress Report on ACTH and Cortisone," "Clinical Application of Radioactive Isotopes in Malignancy," and "Indications for and Contraindications to Blood Transfusions." Thursday sessions will be devoted to surgery, including acute head injuries, severe burns, fractures, carcinoma of the breast and lung, and surgery of the hand, heart, and genitourinary, gastrointestinal, and biliary tracts.

Registration for members of the society will be $3 and for nonmembers $4. Medical students, interns, and residents will be the guests of the congress, if properly certified. Inquiries should be addressed to Dr. Creighton Barker, Executive Secretary, Connecticut State Medical Society, 160 St. Ronan St., New Haven.

DISTRICT OF COLUMBIA

University News.—At the commencement of Georgetown University, June 9, Rev. Paul A. McNally, S.J., Ph.D., dean of Georgetown's School of Medicine and director of its Medical Center, received the degree of honorary doctor of science "in recognition of his administrative as well as scientific ability . . ."

Hunter Award Established.—The Medical Society of the George Washington University, Washington, D. C., has established the Oscar B. Hunter Memorial Fund, in memory of the late eminent pathologist, who, at the time of his death, was vice-president of the American Medical Association. The trust fund will permit a cash award of $100 each year to the university's senior medical student of most notable scholarship in pathology. The first Oscar Benwood Hunter Award in Pathology was recently made at precommencement ceremonies to Allan Hugh Stewart of Mount Shasta City, Calif.

ILLINOIS

Fifty Year Club.—The Madison County Medical Society recently gave a dinner honoring Drs. Alfred E. Everett of Granite City and Mather Pfeiffenberger of Alton, at which they received the 50 year club insignia of the Illinois State Medical Society. Dr. Groves B. Smith, Godfrey, was the toastmaster, and Dr. Edwin S. Hamilton, Kankakee, a trustee of the American Medical Association, was the principal speaker.

Mortality from Communicable Diseases.—A decline of about 7% in mortality from the common communicable diseases was reported in Illinois in 1951. Of nine communicable infections, only three, measles, meningitis, and influenza, were responsible for higher mortality during the year. The number of deaths from measles increased from 8 in 1950 to 33 in 1951. Mortality from meningitis increased from 49 deaths in 1950 to 58 in 1951. Poliomyelitis deaths dropped from 130 in 1950 to 103 in 1951; syphilis from 558 to 490; tuberculosis from 2,215 to 1,890; pneumonia from 2,548 to 2,542; and whooping cough from 22 to 15. A single death from diphtheria was reported for each of the last two years.

Chicago

Society News.—At the annual meeting of the Chicago Gynecological Society, June 20, Dr. Edward M. Dorr was elected president; Dr. Henry Buxbaum, president-elect; Dr. Robert M. Grier, Evanston, Ill., vice-president; Dr. Edwin J. DeCosta, secretary; Dr. Harry Boysen, treasurer; Dr. John R. Wolff, pathologist; and Dr. Janet E. Towne, editor.

Medical Tour for Business Executives.—Research directed toward expansion of life expectancy for persons over 60 was recently demonstrated to Chicago businessmen at the University of Chicago under the sponsorship of 35 Chicago businessmen who form the university's Council on Medical and Biological Research. Key projects in various stages of development, aimed at improving treatment of cancer, degenerative diseases, heart ailments, and high blood pressure, were observed in the laboratories.

Dr. Lowell T. Coggeshall, dean of the division of biological sciences of the university, stated that two hospitals, where research will be concentrated on diseases of the aged, were being completed in the university's medical center at a cost of $4,500,000. Other scientists who spoke during the tours included the following: Dr. Dwight E. Clark, "Hyperthyroidism"; Dr. Charles B. Huggins, "Adrenalectomy"; Dr. Cyrus E. Rubin, "Early Diagnosis of Gastrointestinal Cancer"; Dr. John R. Lindsay, "Causes of Deafness"; James R. Blayney, D.D.S., "Dental Research and Degenerative Diseases"; and Ward C. Halstead, Ph.D., "Psychological Effects of Brain Injuries and Differential Aging."

KANSAS

Dr. Menninger's Ninetieth Birthday.—Dr. Charles F. Menninger, founder of the Menninger Clinic and chairman of the Board of Trustees of the Menninger Foundation, observed his 90th birthday on July 11 in Topeka. Dr. Menninger is a former president of the Shawnee County Medical Society and has served as president of the Topeka Board of Health. He recently presided at a meeting of the foundation's board in Chicago.

MASSACHUSETTS

Dr. O'Hara Resigns as Dean.—Dr. Dwight O'Hara has resigned as dean of Tufts College Medical School, Boston, and will become chief of the professional services at the Veterans Administration Clinics in Boston. He will, however, retain his position as professor of preventive and industrial medicine at

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Tufts. Dr. O'Hara served as vice-dean from 1936 to 1941 and acting dean until 1945, when he was appointed dean of the medical school. He is a past president of the Massachusetts Medical Society.

Personal.—Dr. William A. Hinton has retired as chief of the department of clinical laboratories of the Boston Dispensary after 36 years of service. He will continue to serve in a consulting capacity and will also retain his position as one of the directors in the Institute of Laboratories of the Massachusetts Department of Public Health. Dr. Mario Stefanini, associate research professor in medicine at Tufts College Medical School, Boston, has been appointed acting chief of the clinical laboratories in the Boston Dispensary to succeed Dr. Hinton. Dr. Stefanini is affiliated with the New England Center Hospital and is associate director with Dr. William Dameshek of the blood bank and the hematology research laboratory.——Dr. Alexander J. A. Campbell, clinical professor of surgery at Tufts College Medical School, Boston, has been awarded an honorary doctor of laws degree by his alma mater, St. Francis Xavier University, Antigonish, Nova Scotia.——Dr. Maurice B. Strauss, clinical associate in medicine, Harvard Medical School, Boston, has been appointed professor of clinical medicine at the Boston University School of Medicine.

MICHIGAN

Services Donated to Children's Camp.—Replying to a request from the Burns Attendance Center of the Detroit Public Schools, for free services of physicians to examine about 75 children recommended for the Free Press Fresh Air Camp, seven physicians recently donated their services.

Dr. Eisman Retires.—Dr. Clarence H. Eisman has retired as diagnostician for the Detroit Department of Health after 45 years of service, during most of which he was also in private practice. Since 1947 he has been medical co-ordinator for the Michigan Crippled Children's Commission.

MINNESOTA

State Association Honors Dr. Condit.—Dr. William H. Condit, Minneapolis, was given the Minnesota State Medical Association's distinguished service award, at the recent annual banquet held in Minneapolis. The citation pointed out that "his has been an immeasurable contribution and an individual mark of proud achievement in Minnesota's medical progress." Dr. Condit has served the association for 30 years as councilor, first vice-president, and treasurer.

MONTANA

Surgeons to Meet in Billings.—The Montana Chapter of the American College of Surgeons will hold its annual meeting Aug. 23 at the Northern Hotel in Billings under the presidency of Dr. Raymond E. Benson, Billings.

The following program will begin at 9 a. m.:

Alfred M. Lueck, Livingston, Traumatic Surgical Emergencies in So-Called Minor Surgery.
Sidney C. Pratt, Miles City, Multiple Myeloma.
Neil M. Leitch, Kalispell, Patent Urachus.
Roger Anderson, Seattle, Backache: Practical Methods of Diagnosis and Treatment, and Simple Methods of Treating Difficult Fractures.
Charles W. McLaughlin, Omaha, Emergency Abdominal Surgery in Infancy and Childhood, and The Management of Acute Intestinal Obstruction.
Robert S. McCleery, Great Falls. Technic and Results of a Modified McVay Herniorrhaphy.
Alexander C. Johnson, Great Falls, The Paroxysmal Disorders of the Cranial Nerves.

At 7 p. m. there will be a reception, followed by a banquet for all members and guests. Rev. Father Norbert C. Hoff of Butte will present an address entitled "Tracks." All Montana physicians are cordially invited to attend this conference.

NEVADA

State Medical and Surgical Meeting.—The Nevada State Medical Association and the Reno Surgical Society will hold a joint annual meeting at the Riverside Hotel in Reno, Aug. 20-23. Dr. J. Vernon Cantlon of Reno is president of the state association, and Dr. Kenneth F. MacLean is president of the surgical society. Guests of honor and their first presentations are as follows:

Bernard J. Hanley, Los Angeles, Total Abdominal Hysterectomy for Benign Uterine Disease.
Frederick A. Coller, Ann Arbor, Mich., Cancer of the Colon.
Verne R. Mason, Los Angeles, Eosinophilia.
Charles F. McCuskey, Los Angeles, Changing Concepts in Anesthesia.
Richard P. Middleton, Salt Lake City, Management of Ureteral Calculi.
Alton Ochsner, New Orleans, Early Diagnosis and Treatment of Cancer of the Stomach.
Max Samter, Chicago, Has ACTH Changed Clinical Medicine?
Philip D. Wilson, New York, Treatment of Low Back Pain and Sciatica.

In addition to their lectures, the guest speakers will conduct informal discussions during the luncheon meetings. The Woman's Auxiliary to the Nevada State Medical Association will hold its annual meeting Aug. 21-22.

NEW JERSEY

New Employee Dispensary.—RCA Victor recently dedicated a new $50,000 dispensary for employees of its Camden plant and offices. The new dispensary is air-conditioned and has soundproof ceilings. It is open 18 hours each workday, with a plant physician and five nurses in attendance. Treatment is provided in cases where illness or injury is incurred by employees in the performance of their duties. In cases of illness or injury not incurred in the line of duty, the dispensary gives emergency treatment if required and then refers patients to their own physicians or to hospitals.

Harrison S. Martland Award.—The Essex County Pathological and Anatomical Society offers a prize of $250 under the annual Harrison S. Martland Award for the best unpublished paper on pathology or anatomy. The paper need not be based on original research but may be confined to a review and reinterpretation. The essayist will be known to the committee of judges by number only. Eligibility is limited to resident physicians and interns in the hospitals of New Jersey. Contributions must not exceed 5,000 words. Five copies of each manuscript must be mailed not later than Oct. 15 to Dr. Murray W. Shulman, Newark City Hospital, Newark.

NEW YORK

Study of Convicted Sex Offenders.—Dr. Bernard C. Glueck Jr., Ossining, has been appointed director of the state's study of convicted sex offenders, which has been under way for several years at Sing Sing Prison under the auspices of the New York State Psychiatric Institute. Dr. Glueck, who has been psychiatrist at Sing Sing since 1949, succeeds Dr. David Abrahamsen, who resigned. Dr. Glueck served in the Army Air Force in World War II as flight surgeon.

Dr. Dellaporta to Head Eye Bank.—Dr. Angelos Dellaporta of the University Eye Clinic of Vienna has arrived in Buffalo to head the clinical and ophthalmologic research program of the Buffalo Eye Bank & Research Society, Inc., an organization founded by the Lions Clubs of Western New York, which receives financial assistance from the Lions Blind Seal Committee, Lions Clubs, the general public, and the Community Chest.

Dr. Dellaporta will also lecture in ophthalmology and teach laboratory methods and ophthalmologic and pathological research methods at the University of Buffalo School of Medicine, which cooperated with the Eye Bank in bringing him to America.

New York City

Community Health Control Grant.—Community Research Associates, Inc., has been awarded $550,000 by the Grant Foundation for continuation of basic scientific research to aid the control of health and welfare problems. The projects will involve prevention and control of serious consequences of chronic disease and disability, behavior and emotional disorders, and chronic indigency and dependency. The first year will be devoted to selection and negotiation with cities suitable for experimentation. It is planned that the other four years will see the establishment of simultaneous local projects, the working out of classifications and the control procedures, analysis of findings, and preparation of reports.

NORTH CAROLINA

Postgraduate Symposium.—The New Hanover County Medical Society Symposium will be held in Lumina Ballroom, Wrightsville Beach, Aug. 22. The speakers will include:

H. Hudnall Ware Jr., professor of obstetrics, Medical College of Virginia, Richmond, Toxemia of Pregnancy.
Virgil P. W. Sydenstricker, professor of medicine, Medical College of Georgia, Augusta, Collagen Diseases.
Eugene P. Pendergrass, professor of radiology, University of Pennsylvania School of Medicine, Philadelphia, Cancer of the Lung with Comment Concerning Some of the Difficulties of Early Diagnosis.
Joseph Stokes Jr., professor of pediatrics, University of Pennsylvania School of Medicine, Philadelphia, Recent Studies in Certain Viral Diseases.
Robert L. Sanders, professor of surgery, University of Tennessee College of Medicine, Memphis, Surgical Lesions of the Colon.

The meeting will include a social hour and barbecue dinner in the evening.

TENNESSEE

Aid for Polio Patients.—According to policies established by the Nashville Pediatric Society, only paralytic polio cases in the community are recommended for hospital care. Hospitalization for patients with mild paralysis, however, is usually based on individual need. Suspect cases are referred to the diagnostic service of Vanderbilt University Hospital, which is the referral center for Nashville and the larger area including middle Tennessee, Southern Kentucky, and Northern Alabama. Any physician may refer his patients to the diagnostic clinic for consultation, blood counts, spinal fluid studies, and any other laboratory tests that are needed. A moderate fee is charged for the service. Patients who show no evidence of paralysis are referred back to their physicians for home care.

TEXAS

Postgraduate Conferences.—The Dallas Southern Clinical Society announces the following postgraduate conferences to be held in Room 433, Medical Arts Building:

Sept. 8-11, Cardiology, Tinsley R. Harrison, Alabama, and Don W. Chapman, Houston.
Sept. 29-Oct. 1, Pediatrics and Pediatric Dermatology, Gilbert B. Forbes, Dallas, and J. Lamar Callaway, Durham, N. C.
Nov. 3-5, Obstetrics-Gynecology, Albert W. Diddle, Knoxville, Tenn.

GENERAL

Society News.—At the annual meeting of the New England Society of Anesthesiologists held in Boston, May 13, the follow- g officers were elected for 1952-1953: president, Dr. Henry K. cker, Boston; vice-president, Dr. Stevens J. Martin, Hartford, ı.; and secretary-treasurer, Dr. Francis J. Audin, Boston.

Maxillofacial Surgeons to Meet in San Diego.—The American Society of Maxillofacial Surgeons will hold its annual meeting in San Diego, Calif., Sept. 10-13, at the Hotel del Coronado, under the presidency of Dr. Reed O. Dingman, Ann Arbor, Mich. By invitation the following collaborators will hold a cleft palate symposium on Saturday from 10:30 a. m. to 12 noon.

Herbert A. Ecker, Williamsport, Pa., Management of Premaxilla and Prolabium in Cleft Palate Patients.
Monroe K. Ruch, Los Angeles, Experiences with the Pharyngeal Flap Operation.
Benjamin F. Edwards, Santa Monica, Calif., Evaluation of Cleft Palate Surgery.

Other speakers by invitation include:

Thomas Giannini, San Diego, Calif., Total Nasal Reconstruction.
Michel Dechaume, Paris, France, Myeloplaxes Tumors of Maxillary Bones.
Clarence E. Rees and Maurice J. Brown, San Diego, Calif., Thyroglossal Duct Cysts.
Clyde Litton, Charleston, W. Va., Infantile Cortical Hyperostosis.
Harold I. Harris, Los Angeles, Congenital Unilateral Absence of the Ramus of the Mandible with Suggested Treatment in Young Children.
Alfred A. deLorimier, San Francisco, Arthropathies in the Temporomandibular Joint.
William S. Kiskadden and Sanford R. Dietrich, Los Angeles, and Clifford Barber, Glendale, Calif., Preliminary Review of Treatment of Micrognathia.
Paul A. Shea, San Diego, Calif., Electromyograph as an Aid in Diagnosis and Treatment of Maxillofacial Disease.
David M. Mayer and Wilson A. Swanker, New York, Use of Gelatinous Bone in Facial Defects.

American Society of Human Genetics.—The annual meeting of this society will be held September 8-10 in Martha Van Rensselaer Hall, Cornell University, Ithaca, N. Y., under the presidency of Dr. Franz J. Kallmann of New York. On Monday afternoon there will be a symposium on "The Genetics of Various Constitutional Defects." On Tuesday afternoon a symposium will deal with "Light from Animal Experimentation on Human Heredity." Wednesday morning there will be a symposium on "Counselling Clinics in Human Heredity" and at 11 o'clock a symposium on "Nomenclature in Human Genetics." Wednesday afternoon is left unscheduled so that members may visit laboratories on the campus or attend the symposium on biochemical evolution sponsored by the Society for the Study of Evolution and the American Society of Naturalists.

The annual dinner will be held at 6:15 p. m. in the Terrace Room of the Willard Straight Hotel, at which time the presidential address on "Human Genetics as a Science, as a Profession, and as a Social-Minded Trend of Orientation" will be delivered. Since only 100 persons can be admitted, early reservations may be made through the office of the New York State Psychiatric Institute, 722 W. 168th St., New York 32, before Sept. 3 or may be purchased at the registration desk before noon Sept. 8.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States and its territories and possessions in the weeks ended as indicated:

FOREIGN

Congress on History of Medicine.—The Congress of the International Society for the History of Medicine will convene at Nice, Cannes, and Monaco, Sept. 8-14. The program includes discussion of the precursors, medical relations between the West and the Orient, from empiricism to experimental medicine in the Mediterranean Basin, influence of the schools of Salerno and Montpellier, medical iconography in the 16th century, efforts made in various countries in favor of the teaching of the history of medicine, and the Jean Cantacuzene Commission on medical folklore: prehistoric elements in medical folklore.

Congress on Medical Records.—The First International Congress on Medical Records will be held in London, Sept. 8-12. Sir John Charles, M.D., F.R.C.P., chief medical officer of the Ministry of Health, will deliver the address of welcome. On Tuesday Dr. P. McKinlay, F.R.S., medical statistician, department of health for Scotland, will speak on "Measurement of Morbidity." Friday morning will be devoted to a symposium on "Reporting Systems." Dr. William P. D. Logan, D.P.H., chief medical statistician, general register office, will open the discussion with a presentation on "Cancer Records." Other speakers will talk on records concerned with mental health, tuberculosis, and public health; general practitioners' records; and discharge studies.

International Congress of Neuropathology.—The First International Congress of Neuropathology will be held in Rome, Italy, Sept. 8-13, under the presidency of Dr. Mario Gozzano, professor of neurology and psychiatry at the University of Rome.

Topics for discussion will include the histopathology of demyelinating diseases, cerebral vascular disease, schizophrenia, mental deficiencies, and senility. Physicians from the United States who are scheduled to present papers are Drs. Joseph H. Globus, New York; Jost J. Michelsen, Boston; Karl T. Neubuerger, Denver; W. L. Bruetsch, Indianapolis; Clemens E. Benda, Arlington, Mass.; and George A. Jervis, Thiells, N. Y. Dr. George B. Hassin, Chicago, is an honorary president of the congress.

MEETINGS

American Medical Association Public Relations Institute, Edgewater Beach Hotel, Chicago, Sept. 4-5. Mr. Leo E. Brown, 535 N. Dearborn St., Chicago 10, Director.

Alaska Territorial Medical Association, Anchorage, Aug. 21-23. Dr. William P. Blanton, P. O. Box 2569, Juneau, Secretary.

American Academy for Cerebral Palsy, Durham, N. C., Oct. 2-4. Dr. Meyer A. Perlstein, 4743 North Drake Ave., Chicago 25, Secretary.

American Association of Blood Banks, Hotel Schroeder, Milwaukee, Oct. 9-11. Miss Marjorie Saunders, 3500 Gaston Avenue, Dallas 1, Texas, Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, The Homestead, Hot Springs, Va., Sept. 4-6. Dr. William F. Mengert, 2211 Oak Lawn Ave., Dallas, Texas, Secretary.

American College of Surgeons,Waldorf-Astoria, New York, Sept. 22-26. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Secretary.

American Congress of Physical Medicine, Roosevelt Hotel, New York, Aug. 25-29. Dr. Frances Baker, One Tilton Ave., San Mateo, Calif., Secretary.

American Hospital Association, Philadelphia, Sept. 15-18. Mr. *George* Bugbee, 18 East Division St., Chicago 10, Executive Director

American Medical Writers' Association, Jefferson Hotel, St. Louis, Oct. 1. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

American Physiological Socety, New Orleans, Sept. 4-6. Dr. E. F. Adolph, University of Rochester School of Medicine and Dentistry, Rochester, N. Y., Secretary.

American Roentgen Ray Society, Shamrock Hotel, Houston, Texas, Sept. 23-26. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

Medical Women's International Association, Vichy, France, Sept. 12-16. Dr. Margaret M. Wurts, 27 East Wellesley Road, Montclair, N. J., U. S. A., National Secretary.

Neuroradiological Symposium, Stockholm, Sweden, Sept. 17-20. Docent Ake Lindbom, Symposium Neuroradiologicum, Serafimerlasarettet, Stockholm K., Sweden, Secretary.

Pan American Congress of the Medical Press, Buenos Aires, Argentine, July 12-16, 1953. Secretaria del Congress, 763 Uriburu, Buenos Aires, Argentine.

World Congress of Medicine, Montecatini, Italy, Oct. 16-18. Secretariat: Corso Trieste, 65, Rome, Italy.

World Federation of Mental Health, Brussels, Belgium, Aug. 25-Sept. 1. Dr. J. R. Rees, 19 Manchester St., London, W.1, England, Secretary.

World Medical Association, Athens, Greece, Oct. 12-16. Dr. Louis H. Bauer, 2 East 103d St., New York 29, N. Y., Secretary General.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 23-25. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery.

Alaska:* *Examination.* Juneau. On application in other towns where there are board members. *Reciprocity.* On application. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

Arkansas:* *Examination.* Little Rock, Nov. 6-7. Sec., Dr. Joe Verser, Harrisburg.

California: *Written.* Los Angeles, Aug. 18-21; *Sacramento,* Oct. 20-23. Application must be received at least two weeks prior to date of examination. *Oral for Reciprocity Applicants.* Los Angeles, Aug. 16; San Francisco, Nov. 8. Applicants are requested not to arrange to come to an oral examination until they receive notice from the Credentials Committee. *Oral and Clinical for Foreign Medical School Graduates.* Los Angeles, Aug. 17; San Francisco, Nov. 9. Sec., Dr. Frederick N. Scatena, 1020 N St., *Sacramento.*

Colorado:* *Reciprocity.* Denver, Oct. 14. Exec. Sec., Mrs. B. H. Hudgens, 831 Republic Bldg., Denver.

District of Columbia:* *Reciprocity.* Washington, Sept. 8. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Florida:* *Examination.* Jacksonville, Nov. 23-25. Sec., Dr. Homer L. Pearson, 701 Dupont Bldg., Miami 32.

Georgia: *Reciprocity.* Atlanta, Oct. 14-15. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Ex. Sec., Dr. Austin W. Matthis, Agana.

Illinois: *Examination.* Chicago, Sept. 23-25. Supt. of Regis., Mr. Charles F. Kervin, Capitol Bldg., Springfield.

Kansas: Topeka, Dec. 10-11. Sec., Dr. O. W. Davidson, 864 New Brotherhood Bldg., Kansas City.

Maryland: *Examination.* Baltimore, Dec. 9-12. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore 1.

Michigan:* *Examination.* Lansing, Oct. 8-10. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing.

Minnesota:* Minneapolis, Oct. 21-23. Sec., Dr. J. F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, December. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson 113.

Montana: Helena, Oct. 6-8. Sec., Dr. S. A. Cooney, 214 Power Block, Helena.

Nebraska:* *Examination.* Omaha, June 1953. Director, Mr. Husted K. Watson, Room 1009 State Capitol Bldg., Lincoln 9.

New Hampshire: Concord, Sept. 10. Sec., Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: Examination. Trenton, Oct. 21-24. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

North Carolina: *Reciprocity.* Durham, Oct. 13. Sec., Dr. Joseph J. Combs, 419 Professional Bldg., Raleigh.

Ohio: *Reciprocity. Columbus, Oct. 7. Sec.,* Dr. H. M. Platter, 21 W. Broad St., Columbus.

South Carolina: *Reciprocity.* Columbia, Sept. 3. Sec., Mr. N. B. Heyward, 1329 Blanding St., Columbia.

Tennessee:* *Examination.* Memphis, Oct. 1-2. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

Virginia: *Examination.* Richmond, Dec. 11-13. *Reciprocity.* Richmond, Dec. 10. Sec., Dr. K. D. Graves, 631 First St., S.W., Roanoke, Va.

West Virginia: Charleston, Oct. 13-14. Sec., Dr. N. H. Dyer, *State* Office Bldg #3, Charleston 5.

Wyoming: Cheyenne, Oct. 6. Sec., Dr. Franklin D. Yoder, *State Office* Bldg., Cheyenne.

Virgin Islands: *Examination.* St. Thomas, Nov. 12-13. Sec., Dr. Earle M. Rice, St. Thomas.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: *Examination.* On application. Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arizona: *Examination.* Tucson, Sept. 16. Sec., Mr. Herbert D. Rhodes, Room 423, Liberal Arts Bldg., *University of Arizona,* Tucson.

Arkansas: *Examination. Little Rock, Oct. 1-2. Sec., Mr. Louis E.* Gebauer, 1002 *Donaghey Bldg.,* Little Rock.

Colorado: *Examination.* Denver, Sept. 10-11. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

Connecticut: New Haven, Oct. 11. Address: State Board of Healing Arts, 110 Whitney Ave., New Haven 10.

District of Columbia: *Examination.* Washington, Oct. 20-21. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Florida: *Examination.* Gainesville, Oct. 25. Sec., Mr. M. W. Emmel, Box 340, University of Florida, Gainesville.

Michigan: *Examination.* Detroit and Ann Arbor, Oct. 10-11. Sec., Mrs. Anne Baker, 423 W. Michigan Ave., Lansing.

Minnesota: *Examination.* Minneapolis, Oct. 7-8. Sec., Mr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, Oct. 7-8. Director, *Bureau of Examining* Boards, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

New Mexico: *Examination.* Santa Fe, Sept. 21. Sec., Mrs. Marguerite Cantrell, Box 1592, Santa Fe.

Oklahoma: *Examination.* Oklahoma City, Sept. 13. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., *Oklahoma City.*

Oregon: *Examination.* Portland, Sept. 6 and Dec. 6. Sec., Dr. Charles D. Byrne, State Board of Higher Education, University of Oregon, Eugene.

South Dakota: *Examination.* Vermillion, *Dec. 5-6. Sec.,* Dr. Gregg M. Evans, 310 E. 15th St., *Yankton.*

Tennessee: *Examination.* Memphis, Sept. 24-25. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

Texas: *Examination.* Austin, October. Sec., Brother Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination.* Madison, *Sept. 13, Milwaukee,* Dec. 6. Sec., Mr. W. H. Barber, 621 Ransom St., *Ripon.*

---

* Basic Science Certificate required.

DEATHS

Greene, Edgar Hill ⊕ Atlanta, Ga.; born in Shellman, Ga., Jan. 22, 1889; Emory University School of Medicine, Atlanta, 1915; assistant professor of clinical gynecology at his alma mater; past president of the Medical Association of Georgia; past president and, from 1932 to 1939, a member of the board of trustees of the Fulton County Medical Society; one of the founders of the Southeastern Surgical Congress; member of the Southern Medical Association; fellow of the American College of Surgeons; for many years president of the Atlanta Graduate Chapter of Phi Delta Theta; member and past president of the state board of medical examiners; served in France with the American Expeditionary Forces during World War I, for which service he was decorated by the French government; a major in the Medical Officers Reserve Corps and the Georgia National Guard; retired from the service as a lieutenant colonel; as chairman of the American Preparedness Committee of the Medical Association of Georgia in 1940 headed the procurement and assignment service for physicians, dentists, and veterinarians, and later chairman of a similar committee for the Fourth Service Command; for his service was granted a presidential citation; for many years a trustee of the Good Samaritan Clinic; on the staffs of the Crawford W. Freligh, Clarence Neil ⊕ Waucoma, Iowa; Northwestern University Medical School, Chicago, 1902; died in St. Joseph's Hospital, New Hampton, May 14, aged 74, of primary carcinoma of the liver.

Friedman, Alvin Burton ⊕ Cleveland; St. Louis University School of Medicine, 1942; specialist certified by the American Board of Pediatrics; served during World War II; died in Mount Sinai Hospital May 28, aged 36, of subarachnoid hemorrhage.

Gill, Arthur Francis, Banning, Calif.; University Medical College of Kansas City, Mo., 1901; served during World War I; died April 2, aged 74, of carcinoma of the pancreas.

Gille, Hugo ⊕ Jersey City, N. J.; Jefferson Medical College of Philadelphia, 1902; also a graduate in pharmacy; an Associate Fellow of the American Medical Association; formerly member of the city board of health; at one time on the staffs of the North Hudson Hospital in Weehawken, and Christ Hospital; died May 9, aged 74, of cardiac failure and hypertension.

Gipson, Arthur Albert, Clarksdale, Miss.; Meharry Medical College, Nashville, Tenn., 1915; died May 5, aged 63.

Gjvestvang, George Martin, Ola, Ark.; Kansas City (Mo.) College of Medicine and Surgery, 1917; died May 5, aged 62, of a heart attack.

Glaser, Robert Edward ⊕ Brookville, Ind.; St. Louis University School of Medicine, 1936; served during World War II; affiliated with Margaret Mary Hospital in Batesville and Fayette Memorial Hospital in Connersville; died May 19, aged 41, of accidental carbon monoxide poisoning.

Goodpastor, William H. ⊕ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1907; for many years president of the school board; school physician; affiliated with Presbyterian Hospital; died in Wooster, Ohio, May 17, aged 76, of cerebral hemorrhage.

Gramling, Arthur Burt, Attalla, Ala.; Maryland Medical College Baltimore, 1904; died March 23, aged 71, of bronchopneumonia and hypertensive heart disease.

Grant, Emmet E. ⊕ Seattle; the Hahnemann Medical Colleg and Hospital, Chicago, 1904; died in Virginia Mason Hospita May 12, aged 76.

Green, John Summerfield Jr. ⊕ Towson, Md.; Johns Hopkin University School of Medicine, Baltimore, 1918; past preside of the Baltimore County Medical Society; affiliated with Unic Memorial Hospital, where he died May 26, aged 59, of a cerebr vascular accident.

Greene, Edward Chace ⊕ Colonel, U. S. Army, retired, Wint Park, Fla.; University of Michigan Department of Medicine a Surgery, Ann Arbor, 1904; entered the medical corps of t U. S. Army as a major in September, 1920; member of the N England Society of Psychiatry; formerly medical director of t American Airlines, Inc.; died in the Walter Reed Gene Hospital, Washington, D. C., April 16, aged 76.

Gunderson, Anna Hussey, Lockport, Ill.; Chicago Medi School, 1923; died June 15, aged 69.

Hall, Joe E. ⊕ Maryville, Tenn.; Chattanooga Medical College, 1910; died April 4, aged 64, of a heart attack.

Halsted, Frederick Smith ⊕ Denver; St. Louis University School of Medicine, 1913; member of the American Academy of Ophthalmology and Otolaryngology; affiliated with St. Joseph's and Children's hospitals; died May 1, aged 63, of acute coronary occlusion.

Handel, William Harold, Buffalo; University of Buffalo School of Medicine, 1926; member of the Industrial Medical Association; served during World War I; county medical director; clinical assistant in surgery, Millard Fillmore Hospital, where he died May 9, aged 52, of glioblastoma multiforme.

Hargrove, Reuben Morgan ⊕ Houston, Texas; University of Texas School of Medicine, Galveston, 1912; at one time on the faculty of his alma mater and the University of Oklahoma, Norman; certified by the National Board of Medical Examiners; specialist certified by the American Board of Otolaryngology; served during World War I; fellow of the American College of Surgeons; affiliated with Memorial Hospital, St. Joseph Infirmary, Southern Pacific Hospital, and Hermann Hospital, where he died May 6, aged 68, of coronary occlusion.

Harper, Alexander W. ⊕ Flint, Mich.; Saginaw (Mich.) Valley Medical College, 1903; affiliated with Hurley Hospital and St. Joseph Hospital, where he died May 3, aged 74, of carcinoma of the liver.

Harper, Henry Winston Jr. ⊕ Fort Worth, Texas; Washington University School of Medicine, St. Louis, 1922; fellow of the American College of Surgeons; affiliated with All Saints, Harris, Pennsylvania, and St. Joseph's hospitals; died May 9, aged 55.

Heetland, Louis Herman ⊕ Sibley, Iowa; Michigan College of Medicine and Surgery, Detroit, 1895; died in Sheldon Memorial Hospital, Sheldon, April 20, aged 84, of diabetes mellitus and uremia.

Hendrickson, Berent ⊕ Ringwood, Ill.; Chicago College of Medicine and Surgery, 1911; died in Wonder Lake, April 17, aged 72, of myocardial degeneration.

Hilsabeck, Lester Clyde, Gretna, Neb.; John A. Creighton Medical College, Omaha, 1910; died in Omaha May 15, aged 70.

Holman, Henry Delavan ⊕ Mason City, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1903; died May 21, aged 76.

Johns, Myles Wendel ⊕ Utica, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1903; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; served during World War I; affiliated with Rose Hospital in Rome, Oneida County Hospital, and the Utica Memorial Hospital, where he died June 4, aged 73, of hypertension and cardiovascular disease.

Johnson, Allen Huggins ⊕ Hemingway, S. C.; Medical College of the State of South Carolina, Charleston, 1934; past president of the Williamsburg County Medical Society; medical superintendent and chief of the Johnson Memorial Hospital; president of the Pee Dee Telephone Company; director of the Anderson State Bank; died May 13, aged 41, of acute coronary occlusion.

Johnson, William Paul, Barnesville, Ohio; Starling-Ohio Medical College, Columbus, 1912; formerly county coroner; affiliated with Barnesville Hospital; died May 26, aged 63, of coronary thrombosis.

Kahn, Maximilian ⊕ Cleveland; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1896; a charter member of the Cleveland Academy of Medicine; served on the staff of Mount Sinai Hospital, where he died June 2, aged 79, of fractured hip.

Kaplan, Jacob Copel ⊕ Cincinnati; Tufts College Medical School, Boston, 1919; member of the Massachusetts Medical Society; formerly affiliated with the Veterans Administration Hospital in Lexington; died in Jewish Hospital May 12, aged 54, of myocardial infarction and coronary occlusion.

Kautz, Frank Alexander Sebastian, Cincinnati; Miami Medical College, Cincinnati, 1898; specialist certified by the American Board of Obstetrics and Gynecology; formerly member of the board of education; affiliated with Cincinnati General Hospital, Good Samaritan Hospital, and the Jewish Hospital, where he died May 12, aged 76, of coronary occlusion and diabetes mellitus.

Moore, Johnson McDowell, Penney Farms, Fla.; Atlanta Medical College, 1894; Bellevue Hospital Medical College, New York, 1895; died recently, aged 84, of cerebral arteriosclerosis.

Moore, William Raymond, Vernon, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1914; died May 22, aged 64, of cirrhosis of the liver.

Morgenroth, Frank Charles ⊕ Los Angeles; Chicago College of Medicine and Surgery, 1916; died May 12, aged 63, of cerebral hemorrhage.

Morse, Waldron Lewis ⊕ Springvale, Maine; Yale University School of Medicine, New Haven, Conn., 1933; certified by the National Board of Medical Examiners; past president of the York County Medical Society; a lieutenant in the U. S. Army for three years; on the staff of the Henrietta D. Goodall Memorial Hospital in Sanford; died May 8, aged 43.

Mowry, Jesse E. ⊕ Providence, R. I.; Harvard Medical School, Boston, 1891; member of the House of Delegates, 1916-1917, American Medical Association, of which he had been an Associate Fellow; past president of the Providence Medical Association; for many years treasurer of the Rhode Island Medical Society; on consulting staff, Rhode Island Hospital, where he died May 3, aged 87.

Moyer, Donald Grosch ⊕ Wyomissing, Pa.; Jefferson Medical College of Philadelphia, 1917; served during World Wars I and II; for many years secretary of the board of health; chief of pediatrics, St. Joseph's Hospital in Reading; died May 6, aged 59, of myocardial infarction.

Nathanson, Morris Henry ⊕ Los Angeles; University of Minnesota Medical School, Minneapolis, 1919; associate clinical professor of medicine, University of Southern California School of Medicine; at one time assistant professor of medicine at his alma mater; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; affiliated with Cedars of Lebanon and Los Angeles County hospitals; died April 24, aged 59, of coronary thrombosis.

Oldani, John P., Detroit; Detroit College of Medicine, 1908; died recently, aged 67, of bilateral bronchopneumonia and arteriosclerotic heart disease.

Parnell, Carter C. ⊕ Sledge, Miss.; Missouri Medical College, St. Louis, 1899; died May 18, aged 75, of a heart attack.

Parrella, Dominick ⊕ Brooklyn; Eclectic Medical College, Cincinnati, 1922; affiliated with Caledonian Hospital; died June 6, aged 57.

Payne, Mosby Hale ⊕ New York; Jefferson Medical College of Philadelphia, 1918; died recently, aged 60.

Pernoud, Flavius Gentry ⊕ St. Louis; Washington University School of Medicine, St. Louis, 1907; served during Mexican border campaign; senior instructor in surgery at St. Louis University School of Medicine; formerly instructor in surgery at his alma mater; on the staffs of the Alexian Brothers' Hospital, St. Mary's Group of Hospitals, Lutheran Hospital, and St. Anthony's Hospital, where he died June 9, aged 67, of coronary occlusion.

Person, Hector McLean, Goldsboro, N. C.; North Carolina Medical College, Charlotte, 1913; served during World War I; died in the Wayne Memorial Hospital June 9, aged 68.

Pirosh, Sigmar, Los Angeles; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; died April 20, aged 60, of coronary occlusion.

Purves, George Kern, Wichita, Kan.; Northwestern University Medical School, Chicago, 1900; served during World War I; on the staff of Veterans Administration Hospital, where he died June 7, aged 77, of carcinoma of the prostate.

GOVERNMENT SERVICES

ARMY

Seven New Permanent Army Hospitals.—Construction of the first of seven new permanent hospitals planned for Army posts in this country will begin early next year. The hospitals represent the first step in the Army's program for transferring patients from wooden, cantonment type structures built during World War II to modern multistory structures. Hospitals to be constructed at Fort Benning, Ga., Fort Bragg, N. C., Fort Knox, Ky., and Fort Riley, Kan., are for 500 beds on a 1,000 bed chassis. A new installation at Fort Belvoir, Va., will provide 250 beds initially, expansible to 500; while Fort Monmouth, N. J., will receive a 200 bed facility constructed on a 300 bed chassis. The largest structure will be erected at Fort Dix, N. J., and will furnish 750 beds, expansible to 1,000 beds. The Surgeon General stated that the new facilities incorporate the findings of extensive research in hospital management conducted by the Army Medical Service for the past three years at Valley Forge Army Hospital, Phoenixville, Pa., and at other major hospitals. These new features are expected to economize in the use of nurses, ward technicians, and other scarce personnel. Wards for the critically ill, operating rooms, and clinic facilities will be air-conditioned. The operating rooms will also be equipped to eliminate the danger of anesthetic explosions. All units are expected to be completed in from two to three years.

Dr. Bayne-Jones Named Research Director.—The Department of the Army announces that Dr. Stanhope Bayne-Jones has assumed his duties as civilian technical director of Army Medical Research, and will serve in the office of the Army Surgeon General, succeeding Dr. Francis G. Blake, who died last January. Dr. Bayne-Jones will be responsible for insuring close coordination between the Army's Medical Research effort and similar programs sponsored by the other armed forces and civilian federal agencies.

Since 1947, Dr. Bayne-Jones has been president of the Joint Administration Board of New York Hospital-Cornell Medical Center in New York City. During World War II, he served in the Surgeon General's Office as deputy chief of the preventive medicine service, and as administrator of the Army Epidemiological Board and director of the U. S. Typhus Commission. He was born in New Orleans, received the Bachelor of Arts degree from Yale University, and Doctor of Medicine degree from Johns Hopkins University. During World War I, he served in France and Germany with the British and American expeditionary forces. Among his decorations are the Distinguished Service Medal, the Silver Star with two oak leaf clusters, the Army Commendation Ribbon, and the U. S. Typhus Commission Medal. A former chairman of the Division of Medical Sciences of the National Research Council, Dr. Bayne-Jones has also been president of both the American Association of Immunologists and the Society of American Bacteriologists.

NAVY

Course in Radioactive Isotopes.—About 100 officers of the Navy Medical Department, Air Force, Royal Canadian Army and Navy, U. S. Public Health Service, and Civilian Scientists attended a five day course of instruction, which convened Aug. 4, in medical aspects of special weapons and radioactive isotopes at the Naval Medical School, Bethesda, Md. The training included lectures and demonstrations in nuclear physics; medical problems of radiological safety; operation of blood banks in time of major disaster; radiological defense, disaster planning, and medical aspects of chemical and special weapon warfare; and the medical aspects of civil defense.

Some of the lecturers were Dr. Howard Andrews, Chief, Section on Nuclear Radiation Biology, National Institute of Health; R. E. Lapp, Nuclear Science Service, and Carl Z. Morgan, Director, Health Physics Division, Oak Ridge National Laboratory; Lawrence W. Tuttle, Associate in Radiation Biology, University of Rochester School of Medicine and Dentistry; Herbert Friedman, Head of Electron Optic Branch, Naval Research Laboratory; Murray M. Copeland, Director of Oncology, Georgetown University Medical Center; S. T. Gibson, Associate Medical Director, National Blood Program, American Red Cross; and Douglas W. Overton, International Relations Office, Department of State. The course is conducted primarily for the benefit of inactive reserve medical and dental officers of the Navy and key civilian scientists. Certificates of attendance are issued to each person attending the course. These professional men are qualified to train others and to organize civil defense programs to reduce the destruction caused by this type of warfare.

DEPARTMENT OF DEFENSE

More Physicians to Be Inducted During September.—The Department of Defense has requested the Selective Service System to deliver to armed forces induction stations 355 doctors of medicine and 90 doctors of dentistry during the month of September. The armed forces will assign 180 physicians to the Army and 175 to the Air Force. All of the dentists will be assigned to the Air Force. The September call for physicians and dentists brings to a total of 1,522 the number of physicians and to 650 the number of dentists requested since July, 1951.

PUBLIC HEALTH SERVICE

Training for Foreign Health Workers.—The first health personnel from Iraq, Afghanistan, and Israel to come to the United States for intensive training programs arranged by the Division of International Health of the Public Health Service arrived in June. In addition trainees from six other countries arrived to begin their studies, which are sponsored by federal technical aid programs to foreign countries.

Aid for Employees with Emotional Disorders.—A program to help persons with emotional disorders to get and hold self-supporting jobs has been undertaken by the National Institute of Mental Health and the Office of Vocational Rehabilitation of the Federal Security Agency. As a first step, a two week training course for counselors from state vocational rehabilitation agencies has been begun at San Jose State College, San Jose, Calif., on July 21. Twenty counselors from 12 states are taking the course. At least two additional courses are planned, one at Columbia University, New York, and the other at the Menninger Foundation in Topeka, Kan. The courses are aided by funds made available through NIMH grants to these training centers. Dr. Richard H. Williams of the institute staff will participate in the three courses. Ruth Tiedman, professor of psychology at San Jose State, will be the director of the first course, with Dr. Maurice Grossman, of the Palo Alto Veterans Administration Hospital, and Dr. Henry C. Schumacher, mental health consultant for the Public Health Service at San Francisco, as instructors.

Objectives of the San Jose program are to provide counselors with information regarding human behavior and personality disorders that will help improve vocational rehabilitation programs; to develop more favorable attitudes toward the counseling, training, and placement of clients with neuropsychiatric disabilities; and to promote the use of community resources and consultative services in planning and promoting vocational rehabilitation. Counselors will be given an opportunity to observe and practice, under supervision, the skills and techniques needed in the vocational rehabilitation of emotionally disturbed clients. States sending counselors to the San Jose course are New Mexico, Louisiana, Texas, Idaho, Utah, Washington, Oregon, Colorado, Montana, California, Arizona, and Wyoming.

FOREIGN LETTERS

ARGENTINA

Blood Transfusion Services.—Many hospitals and maternity institutions in Buenos Aires have their own departments for blood transfusion and determination of blood groups. There is an important well-organized central Municipal Service of Blood Transfusion and Plasmotherapy, which is directed by Dr. E. Sammartino. It cooperates with organizations in 11 municipal hospitals of Buenos Aires. The Municipal School of Transfusion for Physicians and Nurses and the Association of Voluntary Blood Donors is also under the direction of Dr. Sammartino. In 1951 the National Institute of Hemotherapy, under the Ministry of Public Health, was responsible for 9,737 blood transfusions, 45,174 blood group determinations, and the production of 95,486 liters of plasma. The Army Hospital also provides important services. Whole blood has been collected mostly in Buenos Aires through an intense program of propaganda and many voluntary blood donors connected with the Institute of Hemotherapy. Plasma is used less than blood, and no other blood substitutes are needed owing to the numerous contributions of whole blood from voluntary sources.

Public Health Achievements.—At the end of the presidential period 1945-1951 the Minister of Public Health published statistical information on progress seen in the last six years. The number of beds in hospital wards increased from 66,000 to 114,609 (73% increase). The specialized institutes increased from 5 to 55. The annual expenses of the Ministry increased from 65 to 276 million pesos. The general mortality rate decreased from 14 to 8.6 per hundred inhabitants. Tuberculosis mortality decreased from 73 to 48 per hundred thousand inhabitants (a 34% decrease). The cases of malaria decreased after the DDT prophylactic campaign from 86,076 to 1,177. The cases of venereal disease decreased 58%. In leprosy 6,032 subjects affected are under sanitary control and treatment. Dr. Ramón Carrillo has been reappointed Minister of Public Health for the second presidential period of Gen. J. D. Perón (1952-1958).

ITALY

Physiopathology of Pulmonary Arterial Circulation.—Professor Condorelli, chairman of the medical clinics at the University of Catania, who is succeeding 70-year-old Prof. Nicola Pende to the chair of medical pathology at the University of Rome, reported in his opening address his studies on pulmonary arterial circulation. The number of persons with pulmonary hypertension who seek the general practitioner's help increases every day. Often, because these patients feel a sensation of precordial distress after strenuous physical exercise, they are confused with patients who have angina pectoris. Administration of drugs indicated for patients with angina pectoris, such as amyl nitrite by inhalation, may aggravate the symptoms. Aside from the fact that patients with pulmonary hypertension present a clinical picture different from that of patients with arterial hypertension of the greater circulation, the drugs that are useful for the latter, such as nicotinic acid, are harmful for persons with hypertension of the pulmonary circulation.

To say that a person with hypertension of the "lesser circulation" or pulmonary circulation does not have a genuine disease of the vessels but has chronic bronchitis, asthma, bronchiectasis, or lesions of the mitral valve is not a sufficient explanation for the fact that drugs that are effective on a pronounced arterial pressure of the systemic circulation do not have any effect on the pulmonary circulation. There is also in the smaller circulation hypertension, i. e., hypertension of the pulmonary artery caused by the effort that venous blood must overcome, through the pulmonary artery and its ramifications, to win the resistance of a lung that, because of previous and present respiratory illness, is not too elastic. We must admit, therefore, that there is no interdependency between the systemic and the pulmonary circulation. In fact, many persons in whom pressure is high when measured with the oscillometer show a normal pulmonary pressure if measured with Hamilton's tensiometer. On the other hand, many patients with pulmonary hypertension have normal or even below normal arterial pressure.

To confirm the existence of this autonomy of functions between the greater and smaller circulation there was need of an irrefutable proof of the different physiological conditions in the two circulatory systems. Condorelli and his co-workers Francaviglia and Truchetti reported on this subject. By means of an instrument that Condorelli made, he proved that, even though stimulation (compression) of the reflexogenic zone of the carotid sinus (Pagano's reflexogenic zone) causes a pronounced drop of the pressure of the systemic circulation, it does not change the pressure of the pulmonary artery. A certain drop of the pulmonary circulation is noticeable only as a consequence of the accompanying bradycardia. By stimulating the chemoreceptors of the greater circulation with nitrites (intravenous injections of sodium nitrite or inhalation of amyl nitrite) and causing an abrupt drop in the tone of the systemic circulation (hypotension), the pulmonary tensiogram shows only insignificant changes, which, at any rate, are attributable to the induced tachycardia. It is like saying that the stimulations that are received by the chemoreceptor centers of the greater circulation are spread only to the vasomotor fibers of the greater circulation and not to the ramifications of the lesser circulation or pulmonary circulation.

Condorelli showed that nicotinic acid causes capillary and precapillary hyperemia, acceleration of the velocity of circulation with increased use of oxygen, transitory increase of arterial pressure followed by a decrease, and the subsidence of eventual angiospasms because of the decreased pressure. From this rises the therapeutic indication of nicotinic acid against angiospastic syndromes caused by hemicrania and cerebral spasms with paretic manifestations. But on the pulmonary circulation, as Condorelli demonstrated, nicotinic acid has the opposite effect, in that it causes a pronounced increase of the pulmonary arterial pressure. The same is true of intravenous administration of aminophylline. This drug, while causing an abrupt decrease of the arterial pressure of the greater circulation, does not have any hypotensive effect on the smaller circulation.

On the contrary, epinephrine and arterenol increase the pressure of the pulmonary circulation. In this way hypertension due to pheochromocytoma proves to be much different from common arterial hypertension. While in the common hypertension of the greater circulation there is no involvement of the pulmonary pressure, in hypertension caused by pheochromocytoma there is simultaneous pressure increase of the two circulations: the smaller and the greater. This may be due to the susceptibility that the pulmonary artery has for the epinephrine and arterenol, which are abundantly produced by the adrenal gland affected with pheochromocytoma. This susceptibility to epinephrine and arterenol suggests the presence of sympathetic fibers in the nervous network of the pulmonary artery.

Acetylcholine and analogous preparations that have great effect on the vagus nerve (on dilatation of the arterial vessels and drop in pressure) do not have any effect on pulmonary hypertension. Moreover, if the effect of acetylcholine is potentiated with a previous injection of neostigmine, a combination that in patients with arterial hypertension brings about a real drop of pressure, there is no effect on the pulmonary pressure. This explains the uselessness of drugs that are believed to have an hypotensive effect on pulmonary hypertension. Finally, if, in a dog that is breathing in a closed circuit, hypertension is caused to rise gradually to a level of 20 mm. Hg (about 26 cm. of water), no "blocking" phenomenon is seen. While in the in-

spirating pulmonary veins the pressure drops to below zero, the pressure of the pulmonary artery increases very slightly: the systolic from 30-32 to 40-42, the diastolic from 10-20 to 30. The arterial pressure of the greater circulation, after a mild initial deflection, returns to its initial levels. If, however, the nervous synapses are blocked with curare and the pulmonary vessels are, therefore, deprived of the possibilities of reacting with their own autonomous mechanisms, even a respiratory hypertension of only 5 mm. Hg in addition to a very mild increase of the pulmonary tension causes, by means of the compression exerted on the capillaries and the pulmonary vein, a true "blocking" that manifests itself with a drop in the arterial pressure of the greater circulation.

In other words, the smaller circulation has its own neuroregulation system, independent from that of the greater circulation. Its autonomy, the study of which will open new therapeutic ways, is demonstrated by the varying behavior towards drugs that are used to check arterial hypertension.

LONDON

Agreement on Wage Plan.—At the Conference of Local Medical Committees, the delegates who represent the 20,000 general practitioners in the National Health Service endorsed a revised plan for distributing the enlarged central pool from which physicians are paid. The plan was formulated by a Working Party composed of British Medical Association and Ministry of Health representatives. The Working Party was set up after the adjudication award of Justice Danckwerts last March, under which four years' arrears of nearly £27 million are owed to the physicians. The award was subject to a satisfactory agreement being reached on distribution of the pool.

The conference will also assist any group of practitioners that does not benefit, when they expected to do so under the Working Party's terms of reference, by internal adjustment. These recommendations will now be referred to the Minister of Health, who will take steps to inform Parliament before the supplementary estimate is submitted in July. If this estimate is approved, it should be possible for payment of the arrears to start before the end of the year.

The terms of reference of the Working Party were as follows: "To secure an equitable distribution of the central pool based upon the recommendations of the Spens Committee, the object being to enable the best possible medical service to be available to the public, and to safeguard the standard of Medical Service by discouraging unduly large lists; at the same time, to bring about a relative improvement in the position of those practitioners least favorably placed under the present plan of distribution, to make it easier for new doctors to enter practice, and to stimulate group practice."

The main recommendations of the Working Party are as follows: (1) reduction in the maximum number of a practitioner's patients (*a*) from 4,000 to 3,500 for a private practitioner, (*b*) from 5,000 to 4,500 for a member of a partnership, provided the average for the partnership is not above 4,000, and (*c*) from 2,400 to 2,000 for each permanent assistant employed; (2) practice areas to be reclassified in three categories: restricted areas, doubtful areas, and "designated" areas, in which new entrants to the service would be eligible to apply for initial practice allowance; (3) new recommendations for the capitation fee including: (*a*) a basic fee of 17 s. (about $2.40) per patient, (*b*) an additional "loading" fee of 10 s. ($1.40) for every patient within the patient load range of 501 to 1,500, and (*c*) a final settlement, as a percentage of previous payments under *a* and *b* above, raising the income per patient from 17 s. in a load of 500 patients to a maximum of 23⅔ s. ($3.31) in a patient load of 1,500, and lowering the income as the load grows to its maximum of 4,000, to nearly £1 ($2.76); (4) a system whereby partnerships can apply to executive councils to be paid in what both partners consider to be the most financially advantageous division of the patients between them, thereby stimulating the formation of partnerships, and (5) a sum of money (about £100,000, or $280,000) to be set aside to stimulate the formation of group practices.

Infectious Hepatitis.—The *British Medical Journal* reported the Harveian Lecture by Sir John McNee, Negius Professor of Medicine in Glasgow University, in which he discussed infectious hepatitis. This disease was formerly called catarrhal jaundice, but now, according to the newer nomenclature, it is called viral hepatitis. In recent years two other forms of hepatitis have become recognized, namely homologous serum jaundice and syringe-transmitted hepatitis.

Infectious hepatitis is known best in its sporadic form but has been observed to spread widely in pandemic form. Usually regarded as benign, it can be highly malignant when epidemic, as revealed by its occurrence in Scandinavia, where there were severe and fatal infections in adults as well as children. It can be compared with spirochetal jaundice (Weil's disease) a rat-borne infection due to a spirochete and well known in military campaigns. During World War I there was no outbreak of infectious hepatitis in France. In World War II, the two types of infection, namely serum jaundice and the syringe-transmitted variety, became enormously important, both in the armed forces and among war workers at home. The pandemic was at its height between 1942 and 1944 and then declined. American soldiers were inoculated with a yellow fever vaccine containing human serum, and, of 28,505 in whom jaundice developed, 62 died. The incubation period is about three months. The virus of acute infectious hepatitis is probably most commonly transmitted by the feces and often by a contaminated water supply. The virus of the homologous serum variety depends almost exclusively on direct injection of blood or serum for transmission.

The two viruses would appear to be distinct because, although they cause diseases that are clinically identical, they have different incubation periods, but McNee gives evidence suggesting that one is a variant of the other. The findings of the Medical Research Council present strong evidence for considering the two viruses as distinct. First, the incubation period of the naturally acquired disease is between 20 and 35 days, but that of the parenterally acquired variety falls between 60 and 120 days. Although the clinical pictures and the histological condition of the liver in the two diseases are similar, there is evidence that a person can be immune to the homologous virus and not to the heterologous virus. In addition, there is a well-established difference in the routes by which artificial transmission can be achieved. Whereas in homologous serum jaundice successful transmission has been obtained only by parenteral administration of serum, infectious hepatitis can also be transmitted by spraying the nasopharynx with infected serum. The virus causing infectious hepatitis has also been conclusively demonstrated in the feces, whereas no evidence of fecal virus has been obtained in patients with homologous serum jaundice. Finally, although in the majority of cases the clinical picture of the two conditions is indistinguishable, many observers have noted a tendency for the homologous serum variety to be severer and more protracted.

The infectious period of both types of the disease appears to be remarkably short, but experimental proof of this is lacking. In an induced case of infectious hepatitis, virus has been detected 3 days before appearance of the first symptom and as late as 8 days after the onset of symptoms, but not 31 days after the onset of symptoms. A chronic carrier state with infectious hepatitis virus in the blood stream does not seem to occur. The history of homologous serum jaundice also shows quite clearly that donors of icterogenic plasma exist in whom no association with patients with infectious hepatitis appears probable. The origin of the icterogenic agent in their blood is therefore completely obscure. There is no evidence at present for McNee's suggestion that the agent arises from ordinary infectious hepatitis virus by adaptation from prolonged sojourn in the human blood. Even if this were so, the stability shown by the two viruses today is such as to justify their classification as distinct varieties despite any possible common origin. In view of the fact that the virus is not yet under laboratory control and cannot be cultured, no means of immunization or other form of prevention is yet possible. Attempts are being made to neutralize the virus in serum by exposure to ultraviolet light, and human serum that contains antibodies can be administered in the form of immune globulin with some measure of success as a preventive after blood transfusion.

College of General Practice.—The establishment of a British College of General Practice was first discussed 100 years ago and has been suggested from time to time ever since, but agreement has never been reached on many important aspects of its objectives and organization. Now a steering committee is engaged in collecting and sifting evidence in preparation of a comprehensive report, which should lead to a plan for the implementation of the college. There would, at present, appear to be no serious opposition to the formation of such an organization.

PARIS

Death of Prof. Henri Hartmann.—Prof. Henri Hartmann, one of the greatest French surgeons, a contemporary of Cunéo and Lecène, died in an accident at the age of 90. He was a pupil of Terrier, an intern at the Bichat Hospital, and later an assistant to Professors Cunéo and Gosset. After Pasteur's memorable communication to the Academy of Medicine in 1878, he was the first to apply aseptic methods at the Bichat Hospital. In 1898, he presented to the Academy of Medicine the first two cases of lasting recovery following operation for cancer of the pylorus. In 1902, he reported a 30% survival rate for cancer of the stomach and a 40% rate for cancer of the rectum operated on according to his method. He also evolved a new method, known under his name, for operating on cancer of the rectosigmoid area through the abdominal route. He is the promoter of the sign of "the distended intestinal loop" in intestinal obstruction. He was a wonderful teacher, preferring clinical teaching at the patient's bedside. He published extensively on gastrointestinal surgery, surgery of genitourinary organs (translated into German), and on operative gynecology (translated into English). He also wrote nine volumes on surgical aspects of clinical anatomy, the main basis of the last one, published in 1951, being composed of records he kept of his surgical patients. He was vice-president of the French League Against Cancer and president of the Association for the Development of Medical Relations with Foreign Countries. In 1926, he presided over the International Congress of Surgery at Warsaw. He was a member of the National Academy of Medicine and Surgery and also a member of 30 foreign scientific societies.

Death of Dr. Jules Tinel.—Dr. Jules Tinel, who died recently at 72, was the son of a well-known professor of anatomy and surgeon. His maternal grandfather was also a professor and surgeon, and his son, too, is a physician. In 1906, Tinel became an intern successively in the services of Professors Siredey, Troisier, Dejerine (Salpétrière Hospital), Landouzy (Laennec Hospital), and Netter (Trousseau Hospital). In 1910, he presented his thesis on "Radiculitis and Tabes," which attracted widespread attention. In 1915-1919 he was chief of the Neuro-Psychiatry Center at Le Mans, and, in 1922, he was nominated Doctor of the Paris Hospitals. From 1936 to 1940, he was chief of the Laboratory of Beaujon, from which he was expelled by the Nazis who took possession of the hospital. He then became chief of the laboratory of the Boucicaut Hospital, which he reorganized. For years he has been general secretary to the Society for Psychiatry. During the occupation he took an active part in the resistance movement. His scientific writings are numerous and deal with neurology, psychiatry, and general pathology. One book on his personal psychiatric experiences, begun while he was imprisoned at Bordeaux, remains unfinished. He described the "tingling sensation," which bears his name, in the regeneration of nerves. He was an ingenious scientist and a first-class technician, who was able to prepare most of his own laboratory instruments. Notwithstanding a severe disease, handicapping him for years, he never ceased his scientific work.

SWITZERLAND

New Antituberculosis Drugs.—After the publication, by Selikoff and Robitzek of New York, of the first results obtained with the derivatives of isonicotinic acid hydrazide, Swiss physicians were surprised to learn that these products were already obtainable without medical prescription in drug stores. The first results obtained after experimentation and trials of isonicotinic acid hydrazide in Switzerland were reported at the meeting of the Swiss Association Against Tuberculosis, held on April 26 in Lausanne. B. Fust, A. Studer, and E. Boehni, of the Hoffmann-La Roche firm in Basel, have shown that the action of isonicotinic acid hydrazide (called "rimifon" in Switzerland) varies markedly, according to the strain of tubercle bacillus, and that the bovine strain is less sensitive than the human strain. J. Morin, head physician of a sanatorium in Leysin, reported the first observations of patients treated with "rimifon." Of 73 cases, 68 had cavitary pulmonary tuberculosis with demonstrable tubercle bacilli and 5 had tuberculous meningitis. Clinically, he observed a feeling of well-being in the patients, weight gain, and, sometimes, a fall in the sedimentation rate. Bacteriologically, 50% of the patients became negative for tubercle bacilli in four to eight weeks after the beginning of treatment. Radiologically, he noted that 20 patients improved, 1 became worse, and 45 remained the same. The patients with tuberculous meningitis improved, but it is necessary to wait some months to give judgment. Less optimistic were E. Tanner, J. Wanner, and Z. Ramer, from the sanatorium of Davos. They also noted improvement in the general health, but they did not observe improvement of the radiological image; chiefly, there was no obliteration of the cavities. On the other side, they frequently observed an exudative or toxic reaction, with an increase of expectoration, increased findings on auscultation, and an elevated sedimentation rate. There exists often a paradoxical relationship between the radiological and the bacteriological picture. The radiological picture shows a worsening when the bacteriological analysis suggests improvement. Tanner reported the case of a patient whose bacilli became a thousand times less sensitive to "rimifon" after only 15 days of treatment. Düggeli compared the efficiency of streptomycin combined with *p*-aminosalicylic acid and "rimifon." It seems that "rimifon" has a tendency to liquefy caseous material, which explains the appearance of cavities sometimes observed in the course of treatment. During the discussion that followed these four presentations, Schoch remarked on the efficacy of "rimifon" in the treatment of cutaneous tuberculosis, of erythema induratum, and in generalized sarcoidosis. Baroni studied the influence of "rimifon" on the metabolism and on the immunologic mechanisms, through the Middlebrook-Dubos agglutination reaction. The levels of agglutination vary rapidly as soon as therapy is undertaken and follow a characteristic curve. It is still impossible to have a definitive opinion of the value of "rimifon" and similar products. As yet, nothing justifies the abandonment of streptomycin and *p*-aminosalicylic acid. But this matter of the new antituberculous drugs has revealed the lack of good distribution of medical information. At present, physicians are informed through the general press and the advertisements of the pharmaceutical industry. The Trudeau Society promptly published an explanation and cautioned against overenthusiasm for "rimifon."

During this meeting, the controversial problem of pulmonary excision for tuberculosis was discussed. Professor Decker, head of the university surgical clinic of Lausanne, underlined the great differences in opinion regarding this problem throughout the world. He made a distinction between absolute and facultative indications. A destroyed lung, bronchial stenosis, and rapidly extending cavities can be considered as absolute indications. More and more, extrapleural pneumothorax and thoracoplasty should be abandoned. Professor Brunner, disciple of Sauerbruch, head of the surgical clinic of Zurich, recalled the success obtained with reversible collapsotherapy. One should thus first try an intrapleural or extrapleural pneumothorax. As for thoracoplasty, when it gives bad results, it should be replaced by excision. As much as possible, one should operate on patients who are still responsive to streptomycin, i. e., those who have received less than 60 gm. of this antibiotic. Most of the complications occur in patients whose tubercle bacilli have become resistant. During the discussion, M. Sommer, who had returned from the United States, said that he believes that the discrediting of pneumothorax and the great number of excisions performed in the United States comes from a poor knowledge of the application of pneumothorax.

CORRESPONDENCE

PRESENT STATUS OF CERTIFICATION IN AVIATION MEDICINE

To the Editor:—At the request of the Interim Board on Aviation Medicine and with the encouragement of the Advisory Board for Medical Specialties, the American Board of Preventive Medicine and Public Health has given consideration over the past 18 months to the possibility of association of preventive medicine and aviation medicine as a specialty certifying board. After numerous joint conferences of the members of the Interim Board in Aviation Medicine and the American Board of Preventive Medicine and Public Health, a proposed affiliation was developed. Under the terms of this proposal, the American Board of Preventive Medicine and Public Health would become the American Board of Preventive Medicine, sponsored, in addition to the sponsorship of the original board, by the appropriate professional associations in aviation medicine. Under this reorganization, it was proposed that candidates might be examined and certified in either (*a*) public health or (*b*) aviation medicine, the standards for examination and certification in public health to remain essentially as they are at present, with the standards for examination and certification in aviation medicine to be such as to meet the basic standards established by the Advisory Board for Medical Specialties. The proposed special training to be required in aviation medicine for eligibility for examination were as follows:

(1) successful completion of two academic years of graduate study in (*a*) the elements of preventive medicine, (*b*) the basic sciences applicable to aviation medicine, and (*c*) aviation medicine, at least one academic year of which study to be pursued in a school, college, or university accredited for the purpose of such graduate study by the Council on Medical Education and Hospitals of the American Medical Association or by the American Public Health Association;

(2) at least one year of residency training in aviation medicine approved by the Council on Medical Education and Hospitals and the American Board of Preventive Medicine; and

(3) a minimum of six years of academic training, residency training, or practical experience in aviation medicine subsequent to the intern year, which includes 1 and 2 above.

This proposal was reviewed by the Advisory Board for Medical Specialties at its meeting on Feb. 10, 1952. After hearing the proposal as presented by the representatives of the American Board of Preventive Medicine and by the Interim Board of Aviation Medicine, the Advisory Board for the Medical Specialties voted to disapprove the proposal at the present time for the following reasons:

1. There are at the present time only two training centers where acceptable training in aviation medicine can be obtained, both of which are military. There are no civilian training centers in aviation medicine at this time.

2. The specialized training requirements as previously outlined were not sufficiently defined nor was there adequate assurance of qualified supervision.

3. There was objection to the restriction of applicants for examination to members of a single medical group such as the Aero Medical Association.

After further discussion, it was moved, duly seconded, and unanimously voted that the Advisory Board for Medical Specialties approve in principle the proposal made by the American Board of Preventive Medicine and Public Health and the Interim Board of Aviation Medicine but that no certificates be issued in aviation medicine until such time as the previously outlined deficiencies in the training program in aviation medicine are adequately corrected and brought back to the Advisory Board for Medical Specialties for approval.

In accordance with this action, the American Board of Preventive Medicine and Public Health amended its articles of incorporation and by-laws, changing the name of that board to the American Board of Preventive Medicine and provision was made for additions to the board membership representing aviation medicine. Otis O. Benson Jr. was elected vice chairman of the Board of Preventive Medicine, representing aviation medicine, and Jan H. Tillisch was elected to membership on the board and was named chairman of the Standards and Examination Committee for Aviation Medicine. Since the February meeting, the Interim Board of Aviation Medicine has received proposals from three universities for the development of specialized training programs in aviation medicine. Plans and facilities for both military and civilian residency training programs have been developed. It is hoped that an application for approval of these residency training programs can be submitted to the Council on Medical Education and Hospitals of the American Medical Association in the near future.

TETANUS FOLLOWING NASAL INJURY

To the Editor:—In The Journal for June 14, page 660, Dr. R. B. Tudor reported a case of tetanus resulting from a foreign body in the nose, and stated that "Only one other case was found in the literature in which tetanus unquestionably resulted from a nasal injury." Dr. Tudor's case reminded me of a patient who died from tetanus following a nasal injury whom I treated more than 25 years ago, a case which, even at this late date, is perhaps worth adding as a third case to the literature. My own recollection of the case has been reinforced by the mother's.

On Feb. 22, 1927, an 18-month-old male child forced a metal button mold into one nostril. The mother heard him cry and removed the piece of metal soon after it had been inserted. Slight bleeding showed that the mucous membrane had been injured. At 6 a. m. on Feb. 28, six days later, the mother found that he could not open his mouth when she offered him a bottle of milk. At 9 a. m. he had a convulsion. When it was over he seemed better for a few hours and was able to swallow a little food. About noon, however, he had another convulsion, followed by a series of convulsions. His muscles became increasingly rigid. After the second convulsion he was given a large dose of tetanus antitoxin at home and was then taken to the City Memorial Hospital in Winston-Salem, where he was given more antitoxin, together with symptomatic treatment. He rapidly grew worse, however, and died the next day, March 1.

Although cultures from the nose were not made, it is difficult to conceive of any organism other than Clostridium tetani that could have given rise to such symptoms. No evidence of any other infection was found, and there was not the slightest break in the skin anywhere else on the child's body. There seems no reason to doubt that this was a fatal case of tetanus and that the point of entry was the injured nasal mucosa.

RIGHT RECTUS RIGIDITY

To the Editor:—I wish to take exception to a statement in The Journal of May 3. On page 29, under the heading "Right Rectus Rigidity," the author states, "We know that it is quite impossible to contract one rectus muscle without contracting the other." While on duty at Valley Forge General Hospital in 1945 in the plastic surgery department, I had frequent occasion to observe a patient who delighted in demonstrating his corporeal achievements. He could, at will, alternately contract and relax first one and then the other rectus abdominis so that the surface of his abdomen gave the impression of a revolving door.

BUREAU OF INVESTIGATION

THE WESTERN MEDICAL CORPORATION MAIL-ORDER "TREATMENT" FOR EPILEPSY

Many physicians have wondered recently what is behind a new type of form that epileptic patients have requested them to sign. It calls for a statement by the physician that the holder thereof is epileptic. It is a new twist in the *modus operandi* of the Western Medical Corporation. It results from the appearance of a representative of the firm before a Senate subcommittee wherein he indicated that the firm would require henceforth a physician's diagnosis of epilepsy before it did business with epileptic "patients."

The concern's headquarters are in Chicago. It dispenses, by mail, phenobarbital and other anticonvulsant drugs, together with vitamins, minerals, and laxatives. The price is now $6 for a 30-day supply. Dr. Harry L. James is the "chief-of-staff."

All of this comes about because of a provision in proposed legislation that would have required personal supervision of a physician before prescription drugs could be shipped in interstate commerce. The provision was stricken from the Durham-Humphrey bill in the Senate Subcommittee on Health of the Committee on Labor and Public Welfare. Representatives of the firm complained to committee members that they would be put out of business and that their customers (they call them "patients") would suffer from having their source of medicines cut off. They got the "patients" to write and wire the subcommittee members that this was so. The result was satisfactory to the firm and confusing, apparently, to some senators. The only evidence received came from the firm and its deluded "patients." Some members of the committee apparently felt that a great service was being denied deserving epileptic voters.

Even after the provision was dropped, Senator Magnuson of Washington obtained unanimous consent to have entered in the Congressional Record [1] a letter from Senator James E. Murray of Montana to the Federal Security Administrator, Mr. Oscar Ewing. Mr. Ewing's department includes, among other agencies, the Food and Drug Administration. The senators feared, apparently, that the Food and Drug Administration was going to do, by regulation, what could not now be done directly by law.

Senator Murray's letter contained a most apt observation in the second and third paragraphs of his item numbered 1. He wrote:

> It is my understanding that if a physician regularly engages in actions actually inimical to the health of his patients, he would be violating both a cardinal principle of the code of medical ethics and the laws governing medical licensure in most of our States.
>
> If this is true and if the physicians wórking for the Western Medical Corp. are in fact endangering the health of their patients by prescribing phenobarbital on the basis of mailed questionnaires, then I must ask why is this regulation needed? Why have not those Western Medical Corp. physicians, who are members of the Illinois Medical Society, been charged with violating medical ethics and, if they are in fact endangering their patients by their practices, expelled from the Society? Surely their fellow doctors know better than we in Washington what practices are bad for patients and most certainly they have obligated themselves to take action against unethical practitioners. Furthermore, why haven't the licenses of all the physicians involved been revoked by the Illinois Board of Medical Examiners if, in fact, these physicians are engaging in practices harmful to their patients? Since neither of these actions has been taken, I can only conclude that the practices followed by the physicians of the Western Medical Corp. are not considered harmful by their fellow practitioners in Illinois. If they are not, then there is no reason for the proposed regulation.

Senator Murray and the members of the subcommittee should not be confused by the testimony of Robert J. Creevy, the vice-president of the firm, which implied that their "staff physicians" were not members of the Illinois State Medical Society by their own choice. The members of the staff, other than Dr. J. J. Hennessy, were well aware of their own ineligibility to membership. Nonetheless, Creevy testified that staff members had never been told that they could not be members of the state society. There is no indication that any of them ever made application.

Dr. Hennessy was then a member of the Chicago Medical Society. The society admitted him to membership when he was engaged in the practice of medicine in Blue Island, Ill., a suburb. He did not inform the society of his present employment. When his membership came up for discussion in the Senate subcommittee, however, it was promptly determined. Dr. Hennessy was expelled.

It is true, however, that no medical society has ever taken official action to urge institution of proceedings to have the licenses of Dr. James and his staff revoked. In good conscience, there is no question but that the senator has a point here. If local medical societies were more aggressive in matters of this kind, they could not later be accused of condoning bad or illegal practice of medicine.

It should be observed, however, that membership in a medical society is one thing and the license to practice medicine another. The state has a medical board that issues licenses and that has defined statutory powers in the matter of suspension and revocation. It is not a matter of record that the board of medical examiners of Illinois has ever questioned the license status of these men.

There is in Illinois (and possibly in Montana) provision for admittance to the practice of law on examination by a board appointed by the state supreme court. The admittance to practice on examination and showing of good moral character is done in the form of a motion to include on the roll of attorneys of the supreme court the name of the successful candidate. If in his career he commits an act that is unethical, he may be brought before a grievance committee of his local bar association. That grievance committee may revoke or suspend his right or "license" to practice law, subject only to appeal to the state supreme court.

It may be argued fairly, therefore, that if the local medical society was directly chargeable with responsibility for the ethical and legal conduct of those admitted to the practice of medicine, it could well be censured for its apparent condonation of what appears to be an unethical and illegal practice of medicine. Neither the Chicago Medical Society nor the Illinois State Medical Society has such powers. Their grievance committees function solely to hear and to determine complaints of unethical conduct of their members. The local medical grievance committee may, on hearing, and for cause, recommend to the society suspension or expulsion of a member. He may appeal to the state committee and to the American Medical Association's Judicial Council. His license to practice medicine is not affected.

Actually, the status of the Western Medical Corporation and its staff physicians can be determined on a state level.

This business has continued now for approximately 30 years. Originally it was the "Western Medical Association." In 1933, however, there was an incorporation of the business under the laws of Delaware. The corporation applied for and received a certificate of authority to transact business in Illinois. A document on file in the office of the Secretary of State of Illinois reads in part:

> Now therefore, I, Edward J. Hughes, Secretary of State of the State of Illinois, by virtue of the powers and duties vested in me by law, do hereby certify that the said Western Medical Corporation is from the date hereof duly authorized for a term of 99 years to transact the following business in this state, namely:
>
> To conduct and carry on a general mail order business. To acquire, establish, maintain and conduct in all its branches a general mercantile business and in connection therewith to carry on all or any of the trades, businesses, undertakings or functions that in any manner are subsidiary, incidental and contributory thereto.
>
> To compound, manufacture, buy, sell, import, export and generally deal in, either at wholesale or retail, in all kinds of drugs, druggist's, sundries, specialties and supplies and pharmaceutical, medical, surgical, hospital, invalid, optical and all other preparations, supplies, specialties, instruments, appliances scientific and other apparatus, machinery and proprietary articles of all kinds.
>
> To engage in any other manufacturing, mercantile and trading business.

At the hearing held last fall before the Subcommittee on Health of the Committee on Labor and Public Welfare of the Senate, Mr. Creevy testified that the firm at that time had 21,000 active "patients." Testimony was offered to the effect that the principal anticonvulsant dispensed is phenobarbital. In some instances bromide preparations are substituted. Dosages average 3 to 4½ grains (0.2 to 0.28 gm.) of phenobarbital per day, with a maximum of approximately 8 or 9 grains (0.51 to 0.57 gm.). Treatments are mailed on the basis of a 30 day supply. Psychological advice was also mentioned in testimony as a part of the package sent to patients. A uniform price of $5 (now $6) is charged, although in cases of need a reduction in price is made.

---

[1] Congressional Record: Senate, May 5, 1952, pp. 4855-4856.

There was also testimony that the business employs 105 people and is conducted by mail. These 105 people therefore must handle an average of 1,000 "patients" a day, on the basis of a five day week. There are four doctors of medicine on the staff. Just how they could give any personal attention to 1,000 "patients" in a day's time rather taxes the imagination. Now there might well be a corps of clerical help. If the clerk thinks a case needs expert attention, one of the physicians might be called on to venture an opinion. It is possible that the clerk might be giving "psychological advice." Droplets of psychological wisdom for epileptics could be "canned."

Further testimony was intended to deny that the firm made any diagnoses. For instance, Mr. Creevy stated:

> If, upon receipt of our reply and additional literature, a prospect wishes to take advantage of our method of treatment, he then, in accordance with our instructions, completes a lengthy case history form which is concerned only with the individual patient. On this form, the questions presented, if answered properly, give our physicians a thorough knowledge of the type and severity of the prospective patient's attacks. Two additional questions of extreme importance which appear on this form are:
>
> (a) Has your case been diagnosed as epilepsy by a physician?
> (b) What is the name and address of this physician?
>
> If the answer to the diagnosis question is 'No', we do not accept the case for treatment under any circumstances, even though the prospective patient may give a vivid description of seizures which are most likely epileptic. We do not attempt at any time to diagnose by mail.

The "history" blank covers two sides of a "legal"-sized form. A box cautions the applicant as follows:

> Answer the questions on BOTH SIDES. These are the very same questions that our physicians would ask if you came here personally. Write the answers to the questions in the convenience of your home and send them to us.

Questions cover age, status, physical items, identity of physician who diagnosed the case as epilepsy, number and severity of attacks, identity of current medication, presence of other diseases named, whether head injury has occurred, symptoms during attacks, and special questions for women and children.

In the opinion of the Bureau and of those physicians to whom the Bureau sent copies of the "patient's case history" blank, there is no other possible reason for such a blank than to enable the corporation (or its staff) to diagnose. As one physician remarked, if this is not diagnosing, then only one question should be asked, "Do you have epilepsy?" A prominent neurologist observed as follows:

> The 'Patient's Case History' . . . is inadequate for diagnosing epilepsy. Of course, the questionnaire states that patients will not be accepted for treatment who have not been diagnosed as epilepsy by a physician. Such a diagnosis, however, may or may not be correct and no reputable physician would accept a patient for treatment without himself examining and questioning the patient. Furthermore, the treatment of epilepsy varies according to the type of the symptomatology and there is a definite attempt in the questions to diagnose the type of attack. This corporation could not adequately treat patients with epilepsy.

Another wrote:

> . . . It is, of course, obvious from this material that patients are solicited to apply directly to this Corporation for treatment and that the data which they have requested from the patient on this form is for the purpose of arriving at some sort of a diagnosis. It must be obvious from this form alone that such diagnoses are made by mail in spite of the statements of the Corporation to the contrary.

A third replied:

> In reply to your questions as to whether the case history blank is actually diagnosis or an attempt thereat, there is no question in my mind whatsoever but that it is an attempt at diagnosis. For the numerous questions definitely attempt to determine the type of attack from which the patient suffers. In addition to that, it relates to the possible cause of such attacks.

All three agreed that the blank was totally inadequate to enable a physician to arrive at a proper diagnosis. Without personal examination of the patient, there could be no ruling out of such matters as brain tumor or the residual of trauma.

One may wonder why the vice-president of the Western Medical Corporation was careful to emphasize the fact that no diagnosing is done by the firm. There is no doubt that the corporation through its agents could not legally "diagnose." From another legal aspect, however, there appears to be a fiction indulged in by the corporation to suit its own purpose: If it is not found to be diagnosing, it should follow that it is not engaged in the corporate practice of medicine. It is only "dispensing" or "selling" drugs. This appears to be an effort at defense, a defense against a *quo warranto* proceedings with a view to judgment at ouster; in plain language, a court order to the firm to get out of business in Illinois. It so happens that there is legal precedent for such action.[2] The Illinois Attorney General's office might well inquire into the actual operation of the Western Medical Corporation. There appears to be an excellent case for such ouster proceedings. To say the least, there is great moral and ethical need for such ouster, if the best interests of epileptics are to be served. This holds true no matter where they may live.

If such action were successful, the persons who are listed on the firm's letterhead as "medical staff" or "chief-of-staff" should then find themselves in violation of that subsection of the Illinois Medical Practice Act that provides for revocation of license under such circumstances. Subsection 9 of Section 16 provides as one of the bases for revocation of license the following:

> Professional connection or association with or lending one's name to another for the illegal practice by another of the treatment of human ailments as a business or professional connection or association with any person, firm or corporation holding himself, themselves or itself out in any manner contrary to this Act.

The Bureau urges now that those in charge of administration and enforcement of the Illinois Medical Practice Act nullify the criticism of Senator Murray. Epileptics are not getting adequate or expert care. The mail-order practice of medicine can never be justified. The Bureau has called attention in the past to the reprehensible character of this promotion.[3] The Federal Trade Commission in 1943 exacted a promise from the firm to cease the misleading advertising practices then followed.

Along this line here is a revealing sidelight on the true character of this business. "Patients" are asked for the names and addresses of other epileptics. The firm, on receipt of such names, sends promotional literature, including a booklet it calls "Gratitude," to the prospective "patient."

"Gratitude" is a collection of testimonials of "grateful patients." It has been published in at least four editions (1936, 1938, 1943, and 1949). From edition to edition the pictures and letters of the same testimonial givers appear in several cases. The firm has modified and edited these testimonials from edition to edition. One wonders just whose testimonials they really are.

In spite of Mr. Creevy's testimony and pressure, which apparently convinced members of the Senate subcommittee, it seems preferable, in the light of modern scientific knowledge, to treat epileptics on the basis of individual care. This observation has been summed up rather pointedly in the following excerpt from a letter received from a staff member of a prominent eastern neurological institute. He has commented in part:

> Epilepsy is a condition which is highly individual with respect to causes and treatment. Seizures may be due to brain tumor which cannot be diagnosed by mail. The fact that a physician has examined the person and made a diagnosis of epilepsy does not mean that no neurosurgical treatment may be required. Among other things, the patient's doctor may not have divulged his fears.
>
> Medical treatment by the [Western Medical] Corporation is limited to phenobarbital, since the newer medicines require personal supervision because of the possibility of serious side effects such as allergic reactions or blood dyscrasia. Most patients require the use of dilantin, mesantoin, tridione or phenurone. However, patients taking the last three must have blood examinations at least monthly or personal observation in case of drug eruption. Obviously, such personal attention cannot be given by mail-order concerns. Consequently, these majority patients cannot be treated properly.

---

[2] In the Kerner case (1936) the Illinois Supreme Court ousted the United Medical Service, which was incorporated and "practiced medicine." (200 N. E. 157).

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Basic Science Acts: Constitutionality of Arizona Basic Science Act.—An information was filed against the defendant, charging him with the unlicensed practice of chiropractic. Before making a decision, the trial judge certified certain constitutional questions to the Supreme Court of Arizona.

It was stipulated that the defendant took the basic science examination but failed to pass. He then took the examination given by the board of chiropractic examiners and passed but was not issued a license because he had failed to pass the basic science examination. Later the defendant commenced the practice of chiropractic without the proper certificate and license. The defendant moved to quash the information that had been filed against him on the ground that the basic science act of Arizona was unconstitutional.

In answering the first question certified to us, said the Arizona Supreme Court, we are confronted with the question of the unlawful delegation of legislative powers to the board of examiners. The court first said that the act itself defined the five basic sciences on which applicants are to be examined and that it did not delegate to the board of basic science examiners the responsibility of establishing the definition of the basic sciences, as the defendant contended. Nor, continued the court, does the act delegate legislative authority to the board, because no provision is made for examination of applicants or the grading of papers. The matter of selecting questions to be asked and the passing on or grading the papers is purely an administrative duty to be performed by the board. It is well established that the legislature may set a general standard for the guidance of a board, such as was done in the basic science law, and then leave the administrative details to the board. The Supreme Court therefor concluded that the basic science act was not unconstitutional as an unlawful delegation of legislative power to the board of examiners in the basic sciences.

The defendant next contended that the act violated the due process clauses of the Arizona and United States constitutions on the ground that the act designated no one to establish a definition of the terms "practice of healing" or "practicing healing" and that no provision was made for notifying applicants at such time as the term "basic science" was specifically defined. The defendant referred to the provisions of the act defining the above mentioned terms and including the phrase "and not otherwise specifically defined." Apparently, said the Supreme Court, the defendant had in mind that these provisions indicated that some independent definition would be made. This of course is erroneous as the phrase obviously means that the terms shall remain as defined by the provisions unless otherwise specifically defined. The defendant further complained that no technical qualifications were prescribed by the act for the members of the examining board and that the limitations imposed thereon tended to discriminate against chiropractic practice. The act provided that the board members be members of the faculty of the University of Arizona; this in itself, said the court, embodied certain qualifications. It cannot be said that every act establishing a board or committee that fails to specifically enumerate extensive and detailed qualifications for its members is for that reason violative of the constitutional due process clauses, in which a general qualification is established in the same act. The guarantee of due process is insured through provisions of the act providing for an appeal from the board's decision to the superior court. The court also found that limiting the appointments of members of the examining board to members of the faculty of the University of Arizona did not tend to discriminate against chiropractors. That was an additional regulating factor affecting all applicants equally.

In a Washington case involving an attack on the Washington basic science law, one of the questions raised was whether a person intending to practice as a chiropractor was deprived of due process because he was required to take an examination in the basic sciences. The Washington statute, said the Arizona Supreme Court, is identical with the Arizona statute except that in Washington chiropractors are not required to pass an examination in bacteriology. The Washington court held that the basic science law was not unconstitutional as a denial of liberty and due process of law. Furthermore, the Michigan Supreme Court upheld an act regulating the practice of the system of chiropractic and held that one desiring to practice that system was not deprived of equal protection of the laws by being required, as a condition for securing a license, to pass an examination in anatomy, histology, embryology, physiology, chemistry, bacteriology, pathology, diagnosis, hygiene, and public health, despite the fact that it was shown that such subjects were not taught in chiropractic schools.

Finally, the defendant contended that the act was ambiguous, indefinite, and a contradiction in terms. We are of the opinion, concluded the court, that the legislature sufficiently and adequately defined the terms used in the basic science act. The Supreme Court, therefore, held that the Arizona basic science act was not unconstitutional for any of the reasons raised by the defendant. *State v. Gee, 236 P. (2d) 1029 (Arizona 1951).*

Pharmacists: Sale of Sodium Amytal Without Prescription.—The plaintiff sued the defendant for actual damages alleged to have resulted from the sale by the defendant of "sodium amytal" without a physician's prescription. From a judgment in favor of the plaintiff, the defendant appealed to the Supreme Court of Oklahoma.

The defendant, Ralph Wootan, was the owner and operator of a drug store wherein he had in his employ the defendant McMillian, as a pharmacist. The plaintiff went to the defendant's drug store to get some medicine to relieve a headache. The defendant, McMillian, sold him eight capsules containing the drug "sodium amytal" and instructed the plaintiff to take them in the same manner as he would take anacin® tablets. The plaintiff took two of the capsules in the drug store; the next day he took four, two in the morning and two later. As a result, the plaintiff was unconscious for two days and was away from his work for about eight days. He was treated during this time by a physician who appeared as a witness at the trial. McMillian sold the medicine to the plaintiff without requiring a physician's prescription and in violation of the law.

Section 9, Title 23, of the Oklahoma statute provides: "In any action for the breach of an obligation not arising from contract, where the defendant has been guilty of oppression, fraud or malice, actual or presumed, the jury, in addition to the actual damages, may give damages for the sake of example, and by way of punishing the defendant." On the basis of this statute, the plaintiff sought to recover actual damages and also punitive damages against the defendant because of the fact that the drug was sold without a physician's prescription. Punitive damages were assessed by the trial court, and the defendant appealed on the ground that the trial court erred in giving an instruction to the jury. The instruction complained of was as follows: "You are instructed that our statutes provide that in any action for the breach of an obligation not arising from contract where it is shown that the defendant has been guilty of violation, of a positive criminal statute or of oppression, fraud or malice, actual or presumed, the jury, in addition to actual damages, may allow damages for the sake of example, and by way of punishing the defendant."

To entitle a plaintiff to recover exemplary damages in an action sounding in tort, said the Supreme Court, the proof must show some element of fraud, malice, or oppression. The act that constitutes the cause of action must be actuated by or must be the result of such gross negligence or such disregard of another's rights as is deemed equivalent to such intent. The instruction complained of in the case at bar, the court continued, had the effect of authorizing recovery of punitive damages if the defendant was merely guilty of violating a positive criminal statute. Such was beyond the scope and meaning of the statute and was in conflict with the conclusion of prior decisions of the Supreme Court of Oklahoma. Accordingly, the portion of the judgment of the trial court awarding punitive damages was reversed. *Wootan v. Shaw, 237 P. (2d) 442 (Oklahoma 1951).*

Interstitial Giant Cell Pneumonia.—The clinical and pathological changes in five infants between the ages of 3 weeks and 1 year with interstitial giant cell pneumonia are described. There was clinical evidence of bronchial involvement without consolidation. Three patients had diarrhea and were dehydrated, and two of them had evidence of nonpurulent pharyngitis. The temperature was either normal or subfebrile. The two patients who were treated with sulfonamide drugs, penicillin, and streptomycin did not respond to the treatment. All the patients died, and three of them suddenly, without premonitory symptoms. Necropsy was performed in all. Besides the usual findings of interstitial pneumonia, there was pathological evidence of generalized lymphatic tissue involvement. Epithelial giant cells containing cytoplasmic inclusion bodies were found in the alveoli and bronchi. Interstitial giant cell pneumonia is considered to be due to a virus. Such a view is supported by the presence of intracellular inclusion bodies, by the epithelial proliferation and metaplasia, by the interstitial type of the pneumonic process, and by the noncontributory bacteriological findings. In the authors' cases there was no clinical evidence of measles, nor were there changes in the lymphoid tissues similar to those described in measles. Interstitial giant cell pneumonia resembles the disease called virus pneumonia of infants, plasma cell pneumonia, or pneumonia of premature infants except for the presence of giant cells. It is suggested that interstitial giant cell pneumonia and virus pneumonia of infants represent a single disease entity caused by a virus.

Penicillin in Scarlet Fever.—Continuous and intermittent treatment with penicillin was given to 386 patients with scarlet fever. Of the 386 patients, 119 received 20,000 to 40,000 units of an aqueous solution of penicillin G intramuscularly every three hours for seven days. The other 267 patients were given 300,000 units of procaine penicillin intramuscularly every 24 hours for seven days. Results in the treatment of scarlet fever were equally good with both regimens. Ninety per cent of all patients were afebrile 72 hours after treatment with penicillin was started. More than 90% were free from Streptococcus pyogenes within 24 hours. The number of complications was reduced. In 8% of the patients nonsuppurative complications developed after treatment was discontinued. With penicillin administered every three hours suppurative complications occurred in 1.7% of the cases, and with penicillin administered every 24 hours in 0.8% of the cases. There were no late sequelae in any patient. The relative mildness of scarlet fever during the past years and the extreme sensitivity of the hemolytic Streptococcus organism to penicillin have combined to eliminate mortality due to this disease and to reduce the incidence of early and late complications.

Trihexyphenidyl (Artane®), Stramonium, and Nondrug Therapy of Paralysis Agitans.—Many patients with paralysis agitans (Parkinson's disease) will be benefited by a combination of drug therapy, physical therapy, and psychotherapy. Objective criteria for measuring changes during therapy were established by recording the patient's efficiency in performing 16 exercises designed to measure function. Subjective changes were evaluated by the patient's answers to 34 standard questions, asked each week. One group of 19 patients were given stramonium, and another of 17 patients were given trihexyphenidyl (artane®). Five patients added after the start of the experiment received no drug therapy during the initial period; later, two were given stramonium, and three trihexyphenidyl. The first period of treatment lasted 16 weeks; in the second period of 14 weeks, the drugs were changed so that the first group received trihexyphenidyl and the second stramonium. The patients were not told what drugs they were receiving, or that the drugs were changed. Trihexyphenidyl was not demonstrably superior to stramonium. Improvement ascribed to medication is often the result of physical therapy and psychotherapy. The patients in both groups and the five added later showed an objectively measurable improvement after 16 weeks; the mean level of efficiency in the objective tests was not greater

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

after 30 weeks than after 16. Mental activities, however, seemed to improve continuously with practice. Subjective evaluation may be misleading; objective tests often failed to substantiate changes reported by the patient.

Acquired Hemolytic Anemia.—Three unusual examples of acquired hemolytic anemia are described, with special reference to the role of autoantibodies in the pathogenesis of the disease. The first patient was a woman with "coated" red cells but without demonstrable autoantibodies or isoantibodies in her serum; nevertheless she died following severe hemolytic reactions after transfusions of blood that was compatible in vitro. The second patient had thrombocytopenia in addition to anemia and icterus, and did not immediately improve following splenectomy. Hemolytic transfusion reactions were explained by sensitization to the Kell (or Si) factor, and avoided by transfusing Kell-negative blood, but the purpura did not improve. The patient's serum failed to clump her own unmodified red cells at body temperature, but autoagglutination occurred at body temperature and refrigerator temperature when the red cells were first treated with proteolytic enzymes. The patient showed clinical improvement when transfusions were withheld and corticotropin was administered. The blood count rose but the purpura persisted. Following discharge from the hospital the blood count and platelet count became normal. Possibly this improvement represents a delayed effect of the splenectomy. To date, the patient has remained well, even though the autoantibodies are still demonstrable in low titer, the cells have become coated again, and the sedimentation rate remains elevated. The third patient had hemolytic anemia as a complication of atypical pneumonia. The anemia was explained by the demonstration of potent cold autoagglutinins in the patient's serum (titer 1,000 units for untreated cells at refrigerator temperature, but scarcely any reaction at body temperature). The patient was given four transfusions of whole blood and recovered completely from the anemia. These observations illustrate the graver significance of autoantibodies, which act preferentially at body temperature even though of low titer, while the patient in case 3 shows that hemolytic anemia due to cold autoantibodies usually has a good prognosis even though the antibodies are of high titer.

Renal Papillary Necrosis.—Renal papillary necrosis has only recently become generally recognized as a distinct pathological entity that occurs almost exclusively in patients with diabetes mellitus or chronic obstruction of the urinary tract. Papillary necrosis, renal papillitis, necrotizing renal papillitis, medullary necrosis, necrotizing pyelonephritis, and papillitis renis necroticans are some of the synonyms for this term. Of the 16 cases described in this report, 14 were verified at necropsy, 1 by the examination of a surgically removed kidney, and 1 by the examination of a necrotic papilla removed cystoscopically. Eleven of the patients were diabetic and four of the remainder had urinary tract obstruction. Six patients exhibited an acute rather fulminating clinical course characterized by several renal or systemic infections with fever, pyuria, progressive azotemia, coma, and death within 17 days of the onset. Eight patients, five of whom are diabetic, had a subacute course that lasted from 30 to 100 days. The third clinical pattern was shown by two patients, both of whom had unilateral renal stone with severe colic and hematuria that were self-limited. The gross and histological changes in the kidneys do not support the hypothesis that there is a "reverse Trueta shunt" in the development of renal papillary necrosis. Thrombosis was rare. Arteriosclerosis, arteriolosclerosis, and bacterial infection were the commonest and most consistent findings in the kidneys, and it is assumed that the earlier onset and greater severity of such vascular changes in patients with diabetes may explain also the high incidence of renal papillary necrosis in diabetic patients. Renal ischemia from vascular disease seems to be the most important predisposing factor in the pathogenesis of the lesion in man. The normal relative ischemia of the renal papillae and subjacent pyramids apparently localizes the lesion to its characteristic site.

Cancer of Cervix Diagnosed After Hysterectomy.—Carcinoma of the cervical stump is apparently declining owing to the increased use of total hysterectomy, but about 1% of the total hysterectomies performed for myoma or uterine prolapse at the woman's clinic of the New York Hospital between 1947 and

1951 resulted in the detection of hitherto unsuspected cervical cancers. Nineteen of these 21 patients had squamous cell carcinoma (9 in stage 0 and 10 in stage 1), while two had adenocarcinoma. Sixteen of the cancers had no physical signs, while five deserved further preliminary study, because of erosion, contact bleeding, or postmenopausal bleeding. Multiple biopsies of the squamocolumnar junction and curettage or aspiration smears of the endocervix would have resulted in preoperative diagnosis of the cancer. Nine of the cancers were in the endocervix and 10 at the squamocolumnar junction, while only 2 were on the exocervix. The cervical cancers that are most likely to be undiagnosed are (1) those of the endocervical canal, (2) squamocolumnar junction cancers, (3) very early cancers of the exocervix, and (4) cancer associated with descensus. None of the patients with stage 0 cancer were treated further. One-half of the patients with stage 1 cancer, and all of the patients with adenocarcinoma received irradiation. No additional surgery was done to remove tubes or ovaries. All patients are living and have no evidence of recurrence. Fourteen patients have been observed for over two years.

Ocular Sarcoidosis.—Sarcoidosis is characterized by the presence in organs or tissue of epithelioid-cell tubercles, and refractile or apparently calcified bodies are frequently present in the giant cells of the tubercles. The characteristic lesions may be replaced by fibrosis, hyalinization, or both. Three cases of Boeck's sarcoid involving the uveal tract are presented. The first patient showed precipitates on the corneal endothelium, and had only enough vision to count fingers at 18 inches. Enlarged inguinal nodes were present, and a biopsy revealed sarcoid. The patient received a total of 360 mg. of corticotropin, parenterally administered, but there was no improvement in vision. The second patient had posterior keratic deposits, as well as a choroidal lesion in the left fundus that was thought to be sarcoid. Biopsy of an enlarged femoral node revealed lesions of Boeck's sarcoid. This patient received a course of old tuberculin, with no improvement. A total of 100 gm. of urethane was administered. Vision improved in the left but not in the right eye. The third patient had myocardial, pulmonary, and skin sarcoidosis in addition to the uveal disease. She received 240 mg. of corticotropin systemically and cortisone was applied locally. Improvement was marked. The final refraction gave vision of 20/70 in the left eye, which had been virtually blind; in the right eye vision improved from light perception to 20/30. It is felt that corticotropin and cortisone may be of some value in the treatment of sarcoidosis involving the ocular structures, and the results in case 3 warrant further trials with these hormones.

Cancer of Rectum Diagnosed by Sponge Biopsy.—Sponge biopsy is a surface biopsy in which tissue is collected with a sponge for microscopic examination. Its efficacy was first tried on 10 surgical specimens from patients with cancer of the colon. Pieces of sponge were firmly rubbed over the base and margins of the ulcerating lesions. Examination of the sponges and absorbed contents revealed the presence of diagnosable cancerous tissue in each instance. Then sponge biopsies from 52 patients with rectal lesions were studied, and 15 were diagnosed as positive for cancer. In 14 the diagnosis was confirmed by surgical biopsy or surgical specimen. In one case additional tissue for confirmation was not available, but subsequent laparotomy revealed an annular lesion of the colon with metastases to the liver. A single piece of tissue removed by surgical biopsy may miss the cancer, but this is not likely with sponge biopsy, which provides many small tissue particles from different areas of the ulcer base and margins. The prognosis of a cancer large enough to be recognizable clinically is likely to be poor, but total removal and complete cure may be possible with a small ulcer that can be identified as cancer only by microscopic examination.

Sciatic Nerve Block in Therapy of Peripheral Vascular Diseases. —The sciatic nerve was blocked with 10 cc. of 1% procaine solution in 42 patients, and paravertebral lumbar sympathetic block was done in 11 patients with peripheral vascular diseases. Readings of the surface temperature of each toe, heel, and ankle showed that sciatic nerve block is as effective as lumbar sympathetic ganglion block, and sometimes a greater degree of vasodilatation is obtained. In the four patients in whom sympathetic block was performed on one side first and then sciatic block on the other, the rise in temperature of the foot was more rapid, more sustained, and greater with sciatic block. Temperature rises varied from 0.5 F to 22 F, and the more complete the block the greater the degree of vasodilatation. The temperature rises within 10 minutes after the block, reaches its maximum in 20 to 30 minutes, and remains elevated for at least one hour. With this method total paralysis of the foot persists for about 45 minutes, with no pain for the patient, who feels at ease and seems to enjoy the increased warmth of the foot. After the anesthesia wears off, the patient experiences euphoria. Two patients with intermittent claudication obtained relief, thus suggesting an increase of blood flow to the muscles. Sciatic nerve block is easier to perform and less painful than paravertebral lumbar sympathetic ganglion block, and complications are rarer. None was reported in these 42 patients, whereas in 1 of the 11 patients in whom sympathetic block was performed a cardiovascular accident resulted in right hemiplegia.

Obesity, Fat Metabolism, and Cardiovascular Disease.—In previous reports concerning serum lipid transport via lipoproteins, Gofman and Jones established that certain classes of lipoproteins are closely associated with development of human atherosclerosis. Then they decided to determine whether obesity exerts pressure on irradiated mucosa. Teeth, irrespective of their condition, should be removed before irradiation unless they are adequately protected, the alveolar process should be prepared and the mucosa sutured. The mucosa should be completely healed before the treatment is started. The incidence of this complication is suggested by the fact that at a New York hospital 235 patients developed irradiation osteonecrosis among a total of 1,819 patients with intraoral cancer. In this paper Cook describes 11 cases of irradiation osteonecrosis. The therapeutic approach to this problem has varied from the recommendation to wait until sequestration to resection of the involved part.

ACTH and Cortisone in Treatment of Sickle-Cell Anemia: Report of Case. M. Sass.—p. 583.

Cortisone and ACTH in Surgery of Craniopharyngiomas.—The complications in surgical treatment of craniopharyngioma result from the proximity of the lesion to the pituitary gland and the hypothalamus. Manipulation in this region is perilous, and the danger is increased because of depression of the pituitary-adrenocortical response to stress. Major complications include disturbances of vasomotor control, temperature regulation, and salt, water, and carbohydrate metabolism. Adrenal substitution therapy in the form of cortisone and corticotropin was first employed by Ingraham and associates as an adjunct to operation for pituitary adenoma. In this paper they record experiences with these drugs in four children who underwent operation for craniopharyngioma. One received corticotropin and three cortisone. The uncomplicated postoperative recovery of these four patients suggests that adrenal substitution therapy is a useful adjunct in the surgical management of craniopharyngiomas in children. The importance of replacement therapy may be even greater from adolescence to middle age, because endocrine deficiency is usually more pronounced in this age range. The relatively short period during which large doses of hormone (200 mg. of cortisone or 100 mg. of corticotropin per day) are administered to these patients precludes most complications that may follow long-term therapy. In the reported cases no untoward effects of the hormonal therapy were noted.

Replacement of Fluid Losses in Surgery.—Three general principles should control fluid therapy: replacement of deficits, maintenance (supplying water, electrolyte, protein, calories, and vitamins), and concurrent replacement of abnormal fluid losses. Deficits in body composition and renal adjustments can be avoided if volume-for-volume replacement of abnormal fluid losses is carried out with solutions similar in composition to those being lost, and at the rate at which the losses occur. A system of fluid therapy has been developed in the department of pediatrics of Yale University School of Medicine that is applicable to patients of all types and ages. Two solutions are used in replacing abnormal fluid losses; a "gastric replacement solution" for losses incurred through gastric suction or vomiting, and an "intestinal replacement solution" for losses incurred through intestinal suction and biliary or pancreatic drainage. Both solutions provide potassium; the gastric replacement solution provides an excess of chloride over sodium ions, preventing the development of metabolic extracellular alkalosis, which leads to severe intracellular potassium depletion, and the intestinal replacement solution provides sodium in excess of chloride, preventing the development of metabolic acidosis. These solutions, which are similar in composition to the secretions they replace, are usually given intravenously, but may be given subcutaneously without reaction. They are often mixed with other fluids used for maintenance therapy, and a 50% solution of dextrose is sometimes added when extra calories are needed. The rate at which they are given has never exceeded 500 cc. an hour. The patient's drainage losses and fluid intake are calculated, frequently at first, later at 12 hour intervals, and the appropriate amount of the proper type of solution is added to the other required fluids for the ensuing period. The solution to be used is determined by the drainage tube location and sometimes by the type of drainage. Examination of patients receiving fluids according to this system revealed no evidence of central nervous system stimulation or depression such as might result from an excess of ammonium ions; edema was not observed; there were no signs of toxicity; the electrocardiogram was not affected; and no urinary abnormalities were detected. All patients expressed a feeling of well-being, and many were intermittently ambulatory.

Paroxysmal Nocturnal Hemoglobinuria.—The hemolysis characteristic of paroxysmal nocturnal hemoglobinuria is related to the physiological drop in the pH of the serum during sleep. Anemia is usually intense, and is accompanied by reticulocytosis, icterus, and leukopenia. Splenomegaly and lymphadenopathy are commonly present. Life may be maintained by supportive measures, but the disease has never been known to disappear either spontaneously or as a result of treatment. Two cases, one of which ended in death, are reported; so rare is the condition that only 45 cases have previously been reported in the literature, and some of these are doubtful. The name "paroxysmal nocturnal hemoglobinuria" is misleading, first, because the hemoglobinuria is not necessarily nocturnal and, secondly, because it is not constant, long periods without it occasionally occurring. Its absence, however, does not mean that the disease is arrested; hemolysis may be active and yet not rapid enough to produce a hemoglobin serum level greater than the renal threshold for hemoglobin. Both the author's patients had an elevated icterus level, an abnormally high reticulocyte count, and a decreasing red cell count even during periods of anhemoglobinuria. Any elevation of temperature precipitates a hemolytic crisis and may endanger the patient's life. Transfusions are needed to raise the hemoglobin level, which falls alarmingly during febrile periods. Transfusions were sometimes accompanied by severe febrile reactions not due to blood incompatibility; when this occurred, hemolysis and hemoglobinuria were intense, but, when no complications accompanied the transfusion, the signs of hemolysis decreased and the urine often cleared completely. The higher the hemoglobin level was elevated the longer the absence of hemoglobinuria. Transfusions had more than a replacement value in these patients; they slowed or suspended the hemolytic process temporarily. Normal red cells cannot be hemolyzed by the disease, and this makes transfusions especially effective. No other treatment proved useful. Administration of riboflavin in one case and of acetylsalicylic acid (aspirin) in both provoked hemoglobinuria. Both patients had intra-abdominal pain, sometimes severe. Deposition of hemosiderin in the renal tubules only, as found at autopsy in the case of one patient, suggests that the actual breakdown of the red cells occurs in the epithelium of these tubules.

Hypertensive Toxemia of Pregnancy.—Aqueous injectable "vergitryl" (a purified extract of Veratrum viride containing known concentrations of the hypotensive ester alkaloids) was used as the principal therapeutic agent in 122 cases of hypertensive toxemia of pregnancy. The average effective intramuscular dose of "vergitryl" is 0.75 unit (0.5 cc.), and the following schedule was established for treating nonconvulsive toxemias, including postpartum preeclampsia: 0.75 unit (0.5 cc.) of "vergitryl" mixed with 1 cc. of 1% procaine solution (to minimize pain at the injection site) is given intramuscularly at once; blood pressure and pulse are recorded every half hour and additional "vergitryl," 0.75 unit intramuscularly, is given whenever the blood pressure exceeds 140/90 (once every hour if needed); if there is no hypotensive effect at the end of one hour, dosage is increased to 0.9 unit (6 cc.). If nausea or vomiting occurs, 50 mg. of pentobarbital sodium may be given intravenously. The patient's response determines the dosage interval; if 0.75 unit of "vergitryl" keeps the blood pressure below 140/90 for three hours, the dose may be repeated at three hour intervals. The amount and dosage interval vary with each patient and become evident as treatment proceeds. Intravenous administration is used in treating convulsive toxemia, which always constitutes an emergency. One physician records the blood pressure every minute while another gives a solution of 1.5 units (1 cc.) of "vergitryl" with 20 cc. of 5% dextrose in water at a rate of 1 cc. per minute until the first 20 mm. fall in systolic or 10 mm. fall in diastolic pressure occurs. The needle is left in the vein, but "vergitryl" administration is suspended, because the pressure frequently drops precipitously in the next one or two minutes. If it does not, "vergitryl" administration is continued at the rate of 1 cc. per minute until the first sign of hypotension appears. The needle is then replaced by a polyethylene catheter, through which all additional medications are given. Blood pressure recordings should be made at 15 minute intervals after the first hypotensive effect occurs, and additional "vergitryl" (half the previous effective dose) given whenever the pressure is 140/90 or more. The need for the drug occurs at definite intervals, which increase in length as the severity of the condition diminishes. Vomiting was the only toxic manifestation, occurring in 16% of the cases, and was easily controlled with moderate doses of pentobarbital sodium given intravenously. There were no maternal deaths and only two fetal deaths in this series.

Surgical Difficulties from Goitrogenic Action of Antithyroid Drugs.—DeCourcy believes that the goitrogenic action is the most serious side-effect of noniodinated antithyroid drugs. The gland, which may already be enlarged, grows still larger in most patients treated with propylthiouracil, methylthiouracil, or methimazole ("tapazole"). The gland becomes quite vascular, and the already great risk of hemorrhage during thyroidectomy is increased by the friability of such a gland. Consequently, the use of strong iodine (Lugol's) solution for 10 or 20 days in preoperative preparation has been indispensable to counteract partially the goitrogenic action of the antithyroid drugs, but it is not certain whether an antithyroid drug should be given with the iodine. DeCourcy stresses iodine's beneficial effects and his conviction that most patients with hyperthyroidism should receive only strong iodine solution in preparation for operation. In almost all hyperthyroid patients iodine administration induces such changes as the following: Tremor is diminished. Tachycardia and palpitation decrease as the heart beat becomes less forceful. Vasomotor instability is replaced by normal reactions. The tendency toward hemorrhage during or after operation vanishes. All these changes are accomplished within 10 days to 2 weeks. The patient is not weakened by prolonged operation or loss of blood and thyroidectomy becomes less hazardous, in contrast to the difficulties and risks of operation after the use of goitrogenic drug plus iodine.

Duplications of Alimentary Tract.—The term "duplication of the alimentary tract" is preferred by the authors because it simplifies the classification of these malformations, which are found in many different locations. In the literature these anomalies are designated by such terms as "enterogenous cysts," "giant diverticula," "ileum duplex," "thoracic cysts of enteric origin," "bronchogenic cysts," and "unusual Meckel's diverticula," apparently because each was believed to be a separate entity. It is the authors' belief that all alimentary tract duplications have a similar origin, regardless of their location. Duplications are spherical or tubular structures that have a smooth muscle layer and are lined with mucous membrane; they are found at any level from the tongue to the anus, and usually are intimately attached to some portion of the alimentary tube. From 1928 through 1950, 67 patients with a duplication of some portion of the alimentary tract, including one with two lesions, were seen at Children's Hospital in Boston. Although 23 of these cases were reported previously, all of them are listed in this study. The fact that this many cases have been observed in one hospital seems to indicate that these abnormalities must occur often enough to warrant the attention of the pediatrician, roentgenologist, and surgeon so that they can be recognized and treated. They should not be confused with mesenteric lymphatic cysts or anomalies arising from a Meckel's diverticulum. Symptoms produced by these lesions usually vary according to their location, their size, and the type of fluid secreted by their mucosa. Duplications should almost invariably be removed, even though they are incidentally discovered and have not as yet given rise to symptoms. The mortality rate in cases treated prior to 1940 was high, but in the 20 cases treated in the last four years there have been no deaths.

Thrombocytopenic Factor in Normal Human Blood.—Sensitivity to normal plasma manifested by symptoms that have been grouped under the definition of "plasma transfusion reaction" has been found to occur consistently in paroxysmal nocturnal hemoglobinuria and, occasionally, in some types of blood dyscrasia and extensive carcinomatosis. Most of these patients exhibit some degree of thrombocytopenia. Transitory thrombocytopenia was observed by Stefanini and Chatterjea to be one of the characteristic features of plasma transfusion reaction. Further studies of the specificity of this finding revealed that temporary but significant reduction in blood platelets usually followed transfusion of compatible blood, plasma, or serum of normal donors into normal recipients or nonthrombocytopenic patients. In almost every case no evidence of clinical reaction occurred at the time of the induced thrombocytopenia. Blood, plasma or serum were transfused into 36 compatible recipients with normal platelet count. The recipients had never been previously transfused. The donors with normal platelet level had been fasting for at least four hours prior to donation. Temporary but significant thrombocytopenia was noted in 32 of 36 persons receiving compatible blood, plasma, or serum from nonthrombocytopenic donors. No spontaneous bleeding manifestations, alterations of the various hemostatic mechanisms, changes in number or activity of the bone marrow megakaryocytes, alterations of function or morphology of the remaining platelets, agglutinating or lysing activity of the recipient's serum against normal platelets were noted. Heparinization of the recipient did not affect the thrombocytopenic effect of the transfusion of compatible plasma. The thrombocytopenic effect was apparently due to a component of plasma, stable at 56 C, not absorbed by Seitz filters nor by ion-exchange resins, but absorbed on $Ca_3(PO_4)_2$ gel, from which it could be eluted with sodium citrate solution. Work is in progress to establish the nature, the mechanism of action of this agent, and its relation to products of platelet destruction.

Salicylates and Experimental Beryllium Poisoning.—Acute beryllium poisoning in mice, produced by the intravenous injection of soluble beryllium salts, usually terminates fatally in three days. Death results from acute liver failure following hepatic focal and midzonal necrosis. Pathological changes have also been observed in the kidney and spleen. Recently, aurintricarboxylic acid, a substance of relatively low toxicity, was found to be an effective antidote when it was administered to mice up to eight hours after they had received LD_{95} amounts of beryllium sulfate intravenously. This protection was attributed to its chelating and lake-forming properties. The present study was undertaken to ascertain if the salicylic acid portion of the aurintricarboxylic acid molecule would be as effective in reversing experimental beryllium intoxication. It was found that intravenously or intraperitoneally administered sodium salicylate in doses of 600 mg. per kilogram of body weight is an effective antidote for acute beryllium poisoning in mice when given up to eight hours after intravenous administration of beryllium sulfate in LD_{95} amounts. Salicylate analogues without the ortho-hydroxy, carboxylic acid grouping were generally ineffective.

Results of Total Gastrectomy.—All cases in which total gastrectomy was performed and in which esophageal and duodenal tissue were observed in the surgical specimen at the Mayo Clinic in the years 1917 to 1948 were reviewed. Total gastrectomy was performed for a malignant lesion in 170 cases and for a benign lesion in 15 cases. In most of the latter cases total gastrectomy was performed for a suspected malignant lesion. Gastrointestinal continuity was established after removal of the entire stomach by anastomosing the end of the esophagus and a loop of the jejunum in 165 of the 185 cases. Esophagoduodenostomy was performed in 15 of the cases, and some other type of anastomosis such as a Roux-Y procedure was employed in the remaining cases. A "diffuse" lesion involving virtually the entire stomach was present in 50% of the 170 malignant cases. Regional lymph nodes were involved in 78% of cases, and extension of the malignant process to neighboring structures was found in 38% of the cases. Grading of the malignant lesions after the method of Broders revealed that grade 4 lesions comprised 66% of the series, 22% were of grade 3, 9% of grade 2, and only 3% of grade 1. Among the 15 benign lesions were 13 inflammatory ulcers, 4 of which were multiple. The operative mortality of total gastrectomy has declined from about 60% in 1917 to about 13% in the last five years. The technique of total gastrectomy, provided it is properly chosen and executed, seems to have little influence on the operative mortality. The authors start giving nourishment by mouth within 48 hours after operation, and feel that in past years they increased the diet too slowly after operation. Six patients, each of whom was subjected to total gastrectomy for a benign lesion, were followed five years after operation. Four of these were alive. Of 50 patients who underwent total gastrectomy for a malignant lesion of the stomach and were followed for 5 years, 9 were alive. Half of the patients who survived total gastrectomy for five years were able to perform their usual work. Half of the remaining patients were able to work part time. All required treatment for anemia. Approximately two-thirds of the patients who survived five years regained their preoperative weight.

Treatment of Aneurysms with Fibroplastic Agents.—In a previous report Berman had demonstrated that a solution of dicetyl phosphate in olive oil produced extensive fibroplasia without necrosis or toxic effects. The present report is concerned with use of this compound in patients who had aneurysms of arteriosclerotic or syphilitic origin. The compound forms an easily injectible suspension, which does not require heating. Experiments on rats indicated that solutions up to 10% destroy almost no tissue cells, and induce fibroplasia slowly. Experiments on dogs revealed that a 2% aqueous solution of sodium dicetyl phosphate may be injected periarterially without toxic effects and with resultant fibroplasia. A 2% aqueous solution of sodium dicetyl phosphate was prepared and autoclaved at 240 degrees, with 15 lb. (6.8 kg.) pressure for 20 minutes. The injections were made through 21 gage needles. Six patients who did not have dissection of the aneurysm wall showed clinical improvement following perisaccular injection of dicetyl phosphate. The material is nontoxic, and does induce fibroplasia equal to that produced by cellophane® wrapping. Perhaps it will be most useful as an adjunct to other modes of treatment, such as partial ligation and the introduction of wire as advocated in abdominal aortic aneurysms by Blakemore; or in conjunction with cellophane® wrapping, which may be used on the "free" sides of the aneurysm, the injection being used posteriorly or at points of attachment where dissection is hazardous. Aneurysms that cannot be treated safely by combined methods may be reinforced by the fibroplasia that results from injection of sodium dicetyl phosphate.

Syndrome Characterized by Urethritis, Conjunctivitis, and Arthritis.—Daguet discusses the syndrome characterized by urethritis, conjunctivitis, and arthritis, which had been termed Reiter's disease, Fiessinger-Leroy's urethro-oculo-synovial syndrome, Waelsch's amicrobic urethritis, or pseudogonococcic enteritis. The variety of symptoms makes [illegible] Urethritis usually appears first, but may be preceded occasionally by an enteritic phase. Within 10 days conjunctivitis may be the predominant feature, continuing for two weeks on an average. If arthralgia develops early, polyarthritis may continue for several months. Emphasis is laid particularly on the associated local manifestations, such as late cutaneous lesions consisting of keratoderma, cornified cones, and urticarious erythema, mucosal lesions involving the internal surface of the cheeks, and digestive disturbances, which may be insignificant or of dysentery or colitis type. The etiology of the syndrome remains doubtful, but there is evidence that ultramicrobes, such as the Chlamydozoa oculogenitale, "L" organisms, and common bacteria in a submicroscopic phase may play a part. Antibiotic therapy is the method of choice. An extensive bibliography covering all the papers published on the subject from 1916 to 1951 is appended.

Tuberculosis of Female Genitalia.—Endometrial biopsy revealed that about 5% of sterile women have tuberculous endometritis. Most of these women feel well and have no gynecological symptom except sterility. In one woman biopsy revealed tubercles in the endometrium, and injection of endometrial fragments caused tuberculosis in a guinea pig. A salpingogram showed that the left tube was blocked at the abdominal end. A radiograph of the chest showed no abnormality. She was treated with streptomycin and *p*-aminosalicylic acid. A year later she was well, and no tubercle bacilli could be grown. A second example shows that there may be no symptoms in more advanced cases of tuberculous salpingitis. This woman had had no significant illness. At laparotomy the left tube was found to be completely disorganized, and there was a small right pyosalpinx with tubercles on the adjacent peritoneum. Microscopic examination confirmed the diagnosis of tuberculosis. Recovery was uneventful after removal of the tubes. Such cases show that "silent" pelvic tuberculosis is an important problem. The author reviews some recently expressed opinions about the spread of tuberculosis to and from the pelvic organs, and includes observations based on 38 recent patients seen at his hospital, including 3 with active pulmonary tuberculosis and 6 with healed pulmonary lesions. If it is accepted that the usual site of initial infection of the genital organs is the tubal mucosa, it still remains to be explained how the tubercle bacilli get to these sites. As to whether the tube is infected from the peritoneum or the peritoneum from the tube, it is probable that both events occur. All evidence is against the possibility that infection ascends from the lower genital tract. Concurrent genital and urinary tuberculosis is uncommon in women, one investigator finding only 4 cases of urinary tuberculosis in 200 cases of tuberculous salpingitis. Among the cases studied for this paper no instance of urinary tuberculosis was found, although every patient with urinary symptoms was studied thoroughly. This rarity of association of genital and urinary tuberculosis is probably explained by the fact that in the female the urinary tract is less closely related to the genital organs than in the male. While studies of patients with infertility due to genital tuberculosis has shown that for the most part they remain in good health without any treatment, all patients for whom this diagnosis is made should be followed.

Surgical Treatment of Chronic Ulcerative Colitis.—Failure of medical treatment, roentgenologic and sigmoidoscopic evidence of pseudopolyposis with the possibility of malignant change, and arthritis are the most important indications for surgical treatment of chronic ulcerative colitis. The best surgical technique is ileostomy and colectomy. A three stage operation for total colectomy is recommended. A terminal ileostomy, which is best performed through a short right transrectus incision, is followed by a subtotal colectomy three to four weeks after a satisfactory functioning ileostomy has been established, and this is followed by a total colectomy three to six months later. The autho operated on 68 patients with this disease during the last 1 years and used this three stage operation in 50 of them. Of th 50 who had ileostomy (mortality 6%), 32 subsequently ha subtotal colectomy (mortality 6.25%), and of these 21 had tot colectomy (no mortality). Although the condition of many these patients was serious when surgery was begun, the progre sive improvement in weight and well-being as the various stag were carried out was remarkable. Carcinoma developed after t operation in six patients in whom the disease had been prese for an average of 19 years. Colostomy in cases of segmen colitis is not indicated, since the disease will spread sooner later. Cecostomy is equally ineffective. One stage ileostomy and colectomy is indicated in patients with pseudopolyposis and in those in whom repeated blood transfusion cannot replace the persistent blood loss. The value of vagotomy as a surgical treatment for this disease is doubted. Ileo-anal anastomosis, appendicostomy, and other operations aiming to preserve the rectal function, although temporarily successful, may be easily followed by relapse and involvement of the remaining rectal segment.

Prolonged Heparin Anticoagulant Therapy.—Thirty-seven patients with thromboembolic diseases were treated with heparin for as long as five weeks. The medication was given intravenously to nine patients every four hours in doses of 50 to 75 mg. for 3 to 14 days by an indwelling needle with a Gorth adapter. Doses of 150 mg. in the form of a concentrated aqueous solution containing 250 mg. of heparin per milliliter were given intramuscularly every 12 hours for 4 to 42 days to 23 patients. Five patients received heparin by both routes. Coagulation times were estimated one hour and four hours after the intravenous and the intramuscular injections, respectively, and again before the next dose was given. In most patients of the group receiving heparin intravenously the maximum clotting times were prolonged temporarily to from 16 to 60 minutes. The minimum clotting time was almost normal at the end of four hours. Local infection around the indwelling needle limited the duration of therapy. In the patients who received heparin intramuscularly the maximum clotting time was reached in 3 to 4 hours and the minimum clotting time was maintained at approximately twice the preheparin level for 9 to 10 hours. Firm pressure applied locally after the injection reduced the tendency to bruising. Painful nodules and hematomas occurred mainly when the dose was given oftener than every 12 hours, when it exceeded 150 mg., when the minimum clotting time was maintained above 20 minutes, and when the patient had high venous pressure and loose inelastic connective tissues. In seven patients the therapy had to be discontinued. One patient died after recurrent myocardial infarction, and another had a mild recurrent infarction despite adequate prolongation of the clotting time. The drug rather than the method of administration may have been ineffective in these cases. The other 35 patients did not have further thromboembolic incidents. Since in acute phases of thromboembolic incidents intravenous injection of heparin is more effective than intramuscular injection, it is suggested that the medication be given intramuscularly only in a later stage of these diseases.

Pulmonary Resection in Bronchiectasis.—Of 118 patients who underwent complete or partial lobectomy for bronchiectasis between 1941 and 1949, a total of 104 could be followed up. Of the 104, 58 were satisfied with the results, 24 were partly satisfied, and 22 were dissatisfied. Thirty-eight of the last two groups were investigated. Four are dissatisfied because they have pain in the chest beneath the scar, coming on usually after exertion. Three are dissatisfied because thoracoplasty has been necessary for empyema following operation. Two are dissatisfied because they have pulmonary tuberculosis. Sixteen patients still have bronchiectasis, including nine who have residual lingular bronchiectasis, following left lower lobectomy, that was present before operation. One patient has residual right middle lobe bronchiectasis following right lower lobectomy. One has residual bronchiectasis of the anterior segment of the right upper lobe following right middle and lower lobectomy. In four patients there is residual contralateral bronchiectasis. One patient has bronchiectasis of the posterior subsegment of the left apicoposterior segment. Fourteen patients complained before and after operation of recurring attacks of what they described as "chest colds." These were attacks of cough with mucoid sputum, with malaise, shortness of breath, and wheezing. The author believes that these 14 men had both bronchiectasis and recurrent bronchitis. Four still have both diseases, but 10 have only recurrent bronchitis. The points Paterson wishes to stress are: First, the importance of complete mapping of the bronchial tree before resection. Second, the importance of being certain that the lingular segment has been properly mapped and that it is free of disease before a left lower lobectomy alone is done. Third, when it is known that residual bronchiectasis will be present, the patient should be warned that the operation may not relieve his symptoms completely. Fourth, if the patient has both bronchiectasis and recurrent bronchitis, removal of the bronchiectatic segment may not cure the bronchitis. Despite occasional failures, resection is an excellent operation and is the only means of permanent cure.

*Therapy and Prophylaxis of Postoperative and Traumatic Circulatory Collapse and of Hypotension Associated with Spinal Anesthesia: Preliminary Report. J. Feuerstake and F. Koenig.—p. 205.

Therapy and Prophylaxis of Postoperative and Traumatic Circulatory Collapse.—L-arterenol by intravenous drip was employed successfully by the authors in treatment of 21 patients with postoperative and traumatic circulatory collapse. Six patients are reported on in detail. One 18-year-old patient had a comminuted fracture of the pelvis, one 54-year-old patient had been subjected to laminectomy for herniation of a nucleus pulposus, and four between the ages of 39 and 67 with arthritis deformans had been subjected to plastic operations on the head of the femur or on the acetabulum. Within two minutes after initiation of the intravenous drip of L-arterenol the blood pressure could be measured distinctly. Measurements of blood pressure and pulse were taken every three to five minutes. The blood pressure could be regulated by increasing or reducing the rate of flow of the drug solution. Graphic recordings of the blood pressure revealed rise of the systolic as well as of the diastolic blood pressure; consequently the mean pressure was increased. This is the most important indication of adequate peripheral blood perfusion. The rise of blood pressure was regularly associated with relative bradycardia, which may be interpreted as being due to central reflex regulation designed to diminish the load on the heart. Within a short time of application of the L-arterenol, respiration became quiet and deep. Hypotension during spinal anesthesia could be prevented by giving L-arterenol by intravenous drip at the onset of anesthesia. The therapeutic advantages of L-arterenol over epinephrine are its lower toxicity and its purely vasoconstrictor effect. Untoward side-effects were not observed.

Chemotherapy of Tuberculosis.—After discussing the use of thiosemicarbazone (amithiozone), streptomycin, and *p*-aminosalicylic acid in the therapy of tuberculosis, Domagk and associates describe in vitro and animal experiments with isonicotinic acid hydrazide and its derivatives. The studies indicate that these drugs have a greater inhibiting effect on tubercle bacilli than *p*-aminosalicylic acid and streptomycin. They are about 100 times as potent as streptomycin and at least 10 times more effective than the most active thiosemicarbazones. Furthermore, the isonicotinic acid hydrazides have this effect even on strains of bacilli that have become resistent to *p*-aminosalicylic acid, streptomycin, and the thiosemicarbazones. Animal experiments also indicate that the hydrazide of isonicotinic acid is more effective in tuberculosis than any other drug.

Clinical Results of Use of Isonicotinic Acid Hydrazide in Tuberculosis.—Humans have great tolerance for isonicotinic acid hydrazide. The optimal daily dose is from 10 and 15 mg. per kilogram of body weight, that is, from 0.5 to 0.9 gm. daily for adults. This quantity is divided into four (usually 0.2 gm.) doses, which are given orally after meals. Variations of this dosage may be necessary, because of cumulative effects. Treatment was usually discontinued for 3 or 4 days following the first 10 days of treatment, when *p*-aminosalicylic acid may be given. In some cases, however, treatment with isonicotinic acid hydrazide was continued for three months without interruption. Dosage should be such that an effective concentration is attained in the blood. Although parenteral administration is not absolutely necessary, the drug is available in a 2% solution for intramuscular injection, and is tolerated without irritation. This 2% solution can also be given intrapleurally; in tuberculous empyema or secondary serous pleurisy 5 cc., equal to 100 mg., can be introduced. In tuberculous meningitis from 1 to 2.5 cc. of a 2% solution, which is equal to 20 to 50 mg., can be dissolved in 10 cc. of cerebrospinal fluid and injected intraspinally. No undesirable secondary effects were observed in adults with this form of intrathecal administration; in children further experiments are necessary. Inhalation of a 1% solution or introduction through Monaldi's tube into cavities and fistulas also proved valuable. Undesirable secondary effects are slight in view of the good tolerance to this drug. Of 126 patients in whom the drug was used, 61 had been treated for from six weeks to five months. More than two-thirds of these 61 patients showed rapid improvement and others remained about the same. Increase in appetite and in weight was observed in almost all patients. Forty-five of the 61 patients had fever at the onset of treatment. In 32 the fever subsided rapidly, but in the other 13 subfebrile temperatures persisted. The sputum became negative in 15 of 58 patients who had bacilli in the sputum at the beginning of treatment. Cavities, which were present in 40 patients, disappeared in four without local intervention or collapse therapy; in 18 considerable shrinkage of the cavities was noted. Roentgenoscopy revealed some regression of foci in 14 of the 61 cases. Isonicotinic acid hydrazide effected improvement in some patients who had not responded to streptomycin, *p*-aminosalicylic acid, and amithiozone. High bacteriostatic potency combined with good tolerance and low dosage are the advantages of this drug.

*Tuberculosis of Lateral Cervical Lymph Nodes: Clinical and Pathogenic Study. B. Lorenzini and V. Maddaloni.—p. 105.
*Hepatosplenography with Ethyl Di-Iodostearate. A. Baronchelli and L. Rossi.—p. 150.

Pathogenesis of Tuberculosis of Cervical Lymph Node.—From 1945 to 1951 the authors studied 93 patients with tuberculosis of the lateral cervical lymph nodes in an attempt to determine whether this infection is lymphogenous or hematogenous in origin. Only six of these patients had a history of lesions of the skin and mucous membranes (conjunctivitis, otitis, or tonsillitis) that are important factors in lymphogenous infection of the cervical lymph nodes. Roentgenograms revealed an old tuberculous process in 64 patients, in 48 of whom it was localized in the respiratory system. At admission these patients were in good general condition, with a slightly increased erythrocyte sedimentation rate, mild hypochromic anemia, strong positive reaction to tuberculin, and mild elevation of temperature in the evening. Lymph node biopsy revealed caseous necrosis in some patients, productive processes, and exudative and inflammatory processes in others. Disseminated micronodular pulmonary tuberculosis of recent origin was present in 14 patients who had intermittent fever with profuse sweating, mild enlargement of the liver and spleen, great increase of the erythrocyte sedimentation rate, pronounced hypochromic anemia, and a negative or very weak reaction to tuberculin. Biopsy revealed discrete or conglomerate tubercles. There is no doubt about the hematogenous pathogenesis of the disease in these patients, but the authors suggest that the disease may have the same origin in the other patients. According to them, if there are no lesions in the skin and mucous membranes, the hematogenous diffusion of tuberculosis to the cervical lymph nodes should be considered in all instances. Clinical, bacteriological, radiological examinations, biopsy and allergy tests, and the history are of great importance.

Hepatosplenography with Ethyl Di-Iodostearate.—A suspension of ethyl di-iodostearate in glucose solution was used as a contrast medium in hepatosplenography. This is an isotonic colloidal suspension of an organic iodine preparation with particles having a maximum diameter of 2 μg. If the diameter of the particles were greater than that of blood capillaries, the substance would produce severe embolism. Since it is 10 to 100 times less, the solution easily traverses the small arteriovenous peripheral and pulmonary capillaries and is retained in the liver and spleen for as long as six days. It is very opaque, painless, easily tolerated, and quickly eliminated. The patient's sensitivity should be tested by intradermal or intravenous injection of 2 cc. of the preparation. The total doses used by the authors ranged from 20 to 35 cc. There were no signs of intolerance to the drug when it was injected into the brachial artery of a patient with swelling of the right forearm, into the subclavian artery of a patient with swelling in the right supraclavicular fossa, and into the dorsal vein of the foot of a patient with varices in the left leg. With 20 cc. the opacity of the spleen was moderate, with almost no visualization of the liver, whereas with 30 to 35 cc. the spleen was clearly visible even in the presence of shadows attributable to pathological processes. The opacity was proportional not only to the amount of preparation but also to the velocity with which it was injected. Opacity in the spleen occurs about three minutes after the injection, increases progressively, is greatest 3 to 4 hours later, and disappears completely after 24 hours. Opacity of the liver occurs after 2 hours, is greatest after 5 to 6 hours, and disappears within 24 hours. Sometimes a slight opacification of the kidney and a late opacification of the gallbladder were obtained.

Chronic Granulocytopenia During Childhood. M. R. Vrtilek.—p. 207.

Effect of Rubeola Virus on Human Fetus.—Töndury applies Bamatter's term "embryopathia rubeolaris" to the defects observed in fetuses and infants of mothers who had rubeola during pregnancy. Although the clinical aspects of embryopathia rubeolaris are well understood, little is known as yet about the processes taking place in the embryo. Töndury was able to make anatomic studies on six fetuses with the typical signs of embryopathia rubeolaris whose mothers had had rubeola between the 35th and 51st day of pregnancy. At the time of interruption of pregnancy or delivery the gestation periods ranged from 68 to 276 days. The eyes, the labyrinth, and the dental structures were studied histologically. The observations indicate that the rubeola virus circulates in the maternal blood and reaches the fetal circulation by ultrafiltration without damaging the chorionic epithelium. It does not produce a systemic disease in the fetus, but attacks and exerts destructive effects only on certain organs, the lens, the epithelium of the internal ear and the enamel organs, that is, it has a decided organ affinity. The destructive process is characterized by swelling and vacuolization and finally there is nuclear pyknosis and the cytoplasm disintegrates into droplets. These destructive processes do not appear simultaneously in all three organs. Whereas the lens fibers show degenerative changes as early as 17 days after the outbreak of the disease in the mother, the cells of the enamel organ and of the inner ear show such changes only 222 days after the maternal rubeola. The author believes that the virus attacks the epithelial cells of the lens, the auditory, and enamel organs during the early embryonic period and remains and multiplies in these tissues. Its effects become evident, however, only after the cells reach a stage of differentiation that is accompanied by great metabolic activity. In this respect the action of the rubeola virus is phase specific. It interferes with metabolic processes in the cell and finally produces degeneration of the cytoplasm.

*Tuberculous Morbidity and Mortality in BCG Vaccinated and Control Groups. R. G. Bacigalupi.—p. 73.

Tuberculous Morbidity and Mortality in BCG-Vaccinated Children.—The clinical histories of 4,986 children treated at the hospital of Dr. Pedro Visca between October, 1943, and October, 1951, showed that 2,804 (56.2%) had received BCG vaccination at birth; most of these came from modest homes and had the same living conditions as others who had not been immunized. The remaining 2,182 (43.7%), consisting chiefly of children who had never been immunized, included an unknown proportion who had been BCG vaccinated; this improves the morbidity and mortality indexes of the control group. There were 26 cases of tuberculosis with 6 deaths in the first group, and 93 cases with 41 deaths in the control group. Analysis of the figures showed 16 cases of tracheobronchial adenopathy, 6 cases of pulmonary and pleuropulmonary tuberculosis, and 4 cases of tuberculous meningitis in the vaccinated group; the corresponding figures for the control group were 35, 11, and 37, with 10 cases of miliary tuberculosis. A striking fact was the absence of tuberculous meningitis among the vaccinated children from September, 1946, to October, 1951; during the same period there were 21 cases among the controls. Disseminated and meningeal infections occurred more than 12 times as often among the nonvaccinated children as among the vaccinated. The mortality figures were probably somewhat higher than the hospital statistics given, because certain children who were removed in serious condition cannot have survived long. BCG vaccination evidently confers protection during the first years of life when tuberculosis is most serious; periodic revaccination until the end of the second year is apparently needed to maintain immunity.

Eye Changes in Congenital Heart Disease.—Ophthalmologic studies were made on 74 patients with congenital cardiac defects, at a time when the exact nature of the defect had not as yet been ascertained. Later it was found that 27 had the tetralogy of Fallot, 15 had Eisenmenger's complex, 11 had patent ductus arteriosus, and 21 had various atypical deformities. The children with patent ductus arteriosus without cyanosis, also had no eye ground changes or polycythemia. However, children with the tetralogy of Fallot or symptoms of congenital cyanotic heart disease had eye changes such as cyanosis of the conjunctivas and retinas, erythema of the optic papillae, tortuosity, and dilatation and darkening of the retinal vessels, particularly of the veins. The degree of eyeground changes corresponded to the severity of the cyanosis and polycythemia. They are regarded as manifestations of compensation. The chronic oxygen deficiency characteristic of this form of heart disease is present also in persons at high altitude, and similar changes are observed in their eyes before acclimatization has taken place.

Celiac Disease: Effect of Wheat Flour.—Ten children with celiac disease, in whom the diagnosis was established by clinical, biochemical and radiological evidence, were studied while they were on a normal hospital diet. As children with celiac disease apparently show the same radiological changes in the small intestine and the same biochemical abnormalities as adults with idiopathic steatorrhea, it seems likely that they have the same defect of absorption in the upper intestine. On the normal hospital diet there was an increase in fecal fat, apparently because of an absorption defect. In these children fat was normally digested and prepared for absorption by fine emulsification, but absorption of particulate fat was delayed and depressed, as shown by the chylomicrographs. The glucose tolerance curves were also compatible with an absorption defect, which may possibly be due to excessive mucus secretion or lack of intestinal motility, as suggested by the radiological findings. Observations of Dicke and the later studies of Weijers and van de Kamer of the Netherlands in 1950, on the beneficial effect of excluding wheat and rye flour from the diet of celiac children, induced the authors of this report to try a wheat free diet. Such a diet produced striking clinical improvement and increased the absorption of fat. The radiographic appearances of the small intestine and the absorption of dextrose and particulate fat also became more normal, suggesting that all absorption had improved. The effect of reintroducing wheat flour or wheat gluten demonstrated that wheat causes deterioration in celiac children. Wheat starch does not have the same action as wheat flour, showing that it is not the starch that is harmful; in fact, children receiving a relatively large amount of starch improved. In the diets prescribed by previous workers, who reported that starches had a deleterious effect in celiac disease, removal of starches was synonymous with removal of wheat flour. The present studies indicate that there is no need to restrict intake of carbohydrates or even fat; choice of food may be almost unlimited, provided that wheat and rye flour are excluded.

Nephrosis Treated by Malaria.—It is known that in nephrosis (type 2 nephritis of Ellis) a remission may sometimes be initiated by such factors as infections, particularly measles, infusions of plasma, and administration of urea, salts such as potassium citrate, or corticotropin. Sometimes the remissions provoked by these means have proved long-lasting and amounted to cures. Since malaria can be easily induced and easily controlled, four patients with the nephrotic syndrome were infected with malaria. The first three of the patients had the nephrotic syndrome in its pure form, with normal or nearly normal blood pressure, no nitrogen retention, and only a few red cells or casts in the urine. In case 4 there was nitrogen retention, and red cells and granular casts were always numerous in the urine; the histological features of the kidney in this case were those of Ellis type 1 nephritis. Malaria induced a striking remission in two of the first three patients, who were still well three years and one year later. In the third child malaria produced no remission, but the plasma cholesterol level fell temporarily from a high to normal level; this response was also seen in the child with a nephrotic syndrome due to a type 1 nephritis. The author suggests that the effect of malaria in nephrosis may be essentially the same as that of corticotropin. In any case, since nephrosis, in its earlier stages at least, may be reversible, the physician should try the agents known to have initiated remissions, and malaria seems worth using in this manner.

Rupture of Testicle.—A man, aged 49, was kicked in the scrotum. When he was seen eight hours later, the scrotum was grossly swollen, and a diagnosis of bilateral hematoceles with a superficial hematoma was made. He had passed urine since the accident, and tests for hematuria were negative. With the patient under anesthesia an incision was made over the left hematocele, and multiple clots were removed. There was a longitudinal rupture of the tunica albuginea, with protrusion of testicular tissue. The tunica was closed with interrupted catgut sutures. Another incision was made over the right hematocele. Many clots were removed, but the testicle presented only a minor contusion. A drain was inserted into each hematocele, and the wounds were closed with catgut sutures. Penicillin and sulfadimidine were given for seven days. Convalescence was uneventful. Seven months later the left testicle was normal. At the time of the operation, the author had thought that the testicle would atrophy. Now he believes that such a prognosis is unwarranted, and recommends exposure and examination of the testicle in every case in which a hematocele follows trauma. If the testicle is ruptured, suture of the tunica albuginea should be attempted instead of orchidectomy.

Pain in Cardiac Infarction.—The reports of 167 consecutive cases of cardiac infarction discovered at postmortem examination were correlated with the clinical histories, which were examined particularly for an account of the pain that might have been associated with the occurrence of the infarct. The term "recent" is applied to infarcts in which fibrosis was not apparent on macroscopic examination, their maximum age being about three weeks. Circumscribed scars are classified as old infarcts. Thirty-nine per cent of the subjects had had recent infarcts only, while in 26% the infarcts were healed. In the remaining 35% of cases, old and recent infarcts were recognizable in the same heart. Pain of cardiac origin (including angina of effort) was recorded in 53% of the patients, vague pain of doubtful origin in 12%, and no pain in the remaining 35%. This indicates that the proportion of cases of painless cardiac infarction is greater than is commonly believed. All subjects with thrombotic occlusion of a coronary artery gave a history of related cardiac pain, but these comprised a total of 19 subjects only. The occurrence of cardiac infarction a short time prior to death was usually accompanied by sudden circulatory failure, often indistinguishable from shock. The onset was often accompanied by sudden congestive cardiac failure, at times by repeated fainting attacks, and occasionally by coma comparable to that of a cerebrovascular accident. On the other hand, in some cases old infarcts were found in subjects who had given histories of angina of effort dating from an acute painless illness, at times called influenza, for which they had not consulted a physician, and in others the infarction had apparently been associated with symptoms mild enough to be considered unimportant by the patient.

Treatment of Wounds with "Septofyllin."—"Septofyllin" (a water-soluble preparation of sodium, copper, and chlorophyll with a quaternary ammonium germicide added) has been used with gratifying results by Carleson and Garsten since 1951 in about 100 cases of ulcers, wounds, and burns. Improvement occurred in all but 1 of the 32 cases of chronic ulcers of the leg, of which 2 were due to frostbite, 5 were traumatic, and 25 were varicose and arteriosclerotic. The ulcers had been present from 2 weeks to 12 years. The treatment was applied for as long as two months. In some cases a week elapsed before improvement was evident. The deodorizing and antipruritic effect was obvious, the bactericidal effect was good, and macroscopically normal granulation tissue was seen. "Septofyllin" is an adjuvant to treatment, not a substitute for adequate surgical or medical therapy.

Corticotropin Therapy of Psychoses.—Eight psychotic patients were treated with corticotropin (ACTH) in daily doses of 40 mg., usually for 7 to 10 days. In the three cases of acute delirium the effect was good, and in two cases life-saving. In a mild manic psychosis the effect was doubtful. In the three cases o endogenous psychosis and in a psychosis of schizophrenic typ the treatment with corticotropin had no effect.

Anal Abscesses and Anal Fistulas.—A series of anal absces and fistulas treated in Bispebjerg Hospital from 1938 to 19 is reported on. In the 211 cases of anal abscess, treatment cc sisted of simple incision, with unroofing done in only one stance. Of 146 patients given a follow-up examination, 109 w well. Recurrence was reported in 33 cases, or 23.3%. Of the cases of anal fistulas 60% were treated by excision, 40% discission. Follow-up examination showed 69 patients to be w Recurrence was reported in 13 cases, or 15.9%. Poulsen s the frequency of recurrence clearly reveals that the more conservative methods of treatment are not so reliable as more radical methods. He concludes that effective treatment of anal abscesses requires broad incision with unroofing of the abscess and removal of the crypt, and that anal fistulas should be excised broadly with vertical division of the sphincter or use of silk ligature. Suture of the sphincter, skin, and mucous membrane is not advised, as it involves considerable danger of recurrence and does not lessen the danger of sphincter insufficiency.

Antituberculosis Vaccination with Petragnani's Anatuberculin.—In 1938 children between the ages of 2 months and 9 years were vaccinated with Petragnani's anatuberculin. Many were malnourished, underdeveloped, syphilitic, rachitic, and dyspeptic. The vaccination was done by Salvioli's technique, which consists of four simultaneous punctures arranged quadrilaterally on the forearm. The total dose of anatuberculin ranged from 0.30 to 0.50 cc., according to the age, weight, and general condition of the child. Only 28 of the children were followed. In those who died while still at the clinic autopsy did not reveal a tuberculous process. In three children seen four to seven months after the vaccination there was no reactivation of the vaccinal focus and the cutaneous allergic reaction was negative. In the other 25 children the inflammatory reaction was reactivated from 20 days to 7 months later. There were no disturbances attributable to the vaccination, and some malnourished children even gained weight. In some children the allergic reaction was still positive after two years, although they had had influenza and whooping cough. In 1950, a clinical and radiological follow-up of six of these children did not reveal a tuberculous process, and the allergic reaction was still positive despite the unfavorable living conditions and the stress of the war. The author believes the antituberculous vaccination with Petragnani's anatuberculin according to Salvioli's technique had had a specific protective action in these children.

Galactorrhea After Thoracoplasty.—Nonpuerperal lactation is reported in a 34-year-old married woman after right thoracoplasty for cavitary pulmonary tuberculosis. The postoperative course was normal, but after two weeks mammary secretion began and persisted for about two months. The mechanism of postoperative lactation is not known. Several hypotheses have been advanced. During pregnancy the production of estrogen and progesterone is increased and breast development proceeds under the stimulation of these steroid hormones derived from the placenta. The onset of lactation following pregnancy is associated with secretion of prolactin by the pituitary and with the postpartum fall in estrogen and progesterone levels that follows removal of the placenta. The maintenance of lactation depends on an afferent neurogenic impulse originating in mechanical sensory stimulation due to suckling, which in turn stimulates the hypothalamus and the pituitary to cause continued prolactin secretion. Probably the most important factor associated with lactation after thoracoplasty is continuous stimulation of the neurogenic component of the lactation mechanism and consequent release of pituitary prolactin due to mechanical injury and inflammation of the thoracic nerves during the operation. The inflammatory stimulation of the cut nerve ends may be regarded as equivalent to the stimulus derived from the suckling reflex. Some authors explain lactation after thoracoplasty on the basis of the alarm reaction of Selye. In this report the authors review 14 cases of galactorrhea reported in the literature.

Hamartoma of the Liver. O. F. Longo, J. César and J. Aguirre.—p. 258.

Renal Carbuncle.—The existence of a renal carbuncle may be suspected when a patient who has recently had furuncles or some other staphylococcic infection has evidence of severe infection, with signs of localization in the kidney. Renal carbuncle should be especially suspected if the kidney is enlarged and painful to the touch, there is a diminished kidney function paralleling in degree the extent of the disease, and if the urine shows no abnormality other than a slight albuminuria (resulting from toxicity). Pyelography is a valuable diagnostic aid; the images shown are those accompanying renal tumors, including compression, displacement, deformation, or amputation of the calyces, and sometimes lacunae or cavities caused by filling of necrotic areas. Symptoms such as muscular contraction, intense local pain, and those resulting from psoitis relate more to perinephritic phlegmon, which almost always complicates the condition, than to the renal carbuncle itself. Perirenal abscess is usually posterior, between the kidney and Gerota's fascia, and if untreated will perforate the fascia and lead to infection of the retroperitoneal tissues. An anterior perirenal abscess will perforate the peritoneum, causing acute abdominal symptoms. Renal carbuncle and perirenal abscess must be differentiated from various conditions with similar symptoms, such as retroperitoneal and subphrenic phlegmon and abscesses, and renal tumors. Nephrectomy, drainage, and enucleation of the carbuncle each have their advocates; no single treatment will be satisfactory in all cases. Antibiotics will often cure mild carbuncles diagnosed early; others may be successfully treated by enucleation or partial resection. Drainage of perirenal phlegmon is usually insufficient when there is an underlying carbuncle; in any case, it should be followed by renal decapsulation. Nephrectomy should be done in cases in which the kidney is extensively involved, or the patient's condition disquieting.

Shoulder-Hand Syndrome in Coronary Disease.—The massive swelling and severe pain of the shoulder-hand syndrome may not appear until some time after the causative coronary accident and may, as a result, be attributed to local conditions such as arthritis of the shoulder or hand, scapulohumeral periarthritis, or phlegmon of the hand. The underlying heart disease may be unrecognized because its symptoms resemble those of gastric or hepatic diseases. The arm on the affected side is held in a sling position and even slight movement increases the pain, which is not relieved by nitrites but is lessened by acetylsalicylic acid (aspirin) and similar substances. The local symptoms are caused by vasomotor reactions of the skin, edema of an inflammatory type in the subcutaneous cellular tissues, muscular atrophy and contracture, metacarpal and interphalangeal arthritis, and osteoporosis of the epiphyses. Complete cure takes place in some cases; in others the condition becomes chronic, with exacerbations depending on the underlying coronary disease. Treatment of the underlying disease and cervicodorsal radiotherapy (from the fourth cervical to the second dorsal vertebrae) proved beneficial in the author's cases.

*First Trials of Transfusion of Leukocytes and Platelets Labeled with Radioactive Phosphorus in Man. J. Julliard, B. Maupin, A. Loverdo and others.—p. 518.

Transfusions of Leukocytes and Platelets Labeled with Radioactive Phosphorus.—Leukocytes obtained from normal blood were labeled by being brought into contact with radioactive phosphorus for two hours. A technique of rapid separation in siliconized flasks permitted completion of the entire procedure of collecting, separating, and labeling in six hours. A transfusion of the labeled leukocytes was then given to a man with chronic lymphoid leukemia and an equivalent amount of radioactive phosphorus in an inorganic solution was administered intravenously to another patient with chronic myeloid leukemia. The transfused leukocytes could be traced in the circulating blood of the recipient, and results showed that the radioactive phosphorus bound to the leukocytes disappeared much more rapidly from the circulating blood than the free radioactive phosphorus. Rabbits were then given intravenous injections of human leukocytes labeled in vitro with radioactive phosphorus. The liver and the lungs proved to be the organs with the greatest radioactivity in the animals that were killed 15 to 30 minutes after the injection. Most of the radioactivity was observed in the lungs, and this was correlated with microscopic demonstration of engorgement of the pulmonary capillaries with leukocytes. In the animals killed three hours to four days after the injection, these differences in radioactivity became less pronounced, and the spleen also showed considerable radioactivity. In the control animals that had been given injections of radioactive phosphorus in inorganic solution, the radioactivity of the lungs was insignificant regardless of when the animals were killed. In additional experiments platelets obtained from 5 liters of human blood were labeled with radioactive phosphorus by the same technique as that used for labeling human leukocytes in vitro. A patient with acute leukemia was given in the course of two hours a transfusion of 100 cc. of a suspension of these platelets. Studies on specimens of blood withdrawn from the patient at various intervals after the transfusion suggested that the transfused platelets disappear rapidly and that the diffusion of the radioactive phosphorus in the circulating blood is imperceptible after two hours. In rabbits killed 20 to 30 minutes after the injection of platelets labeled with radioactive phosphorus, the greatest radioactivity was observed in the spleen, which seems to play a part of selective fixation comparable to that shown by the lungs with regard to the leukocytes.

*The General Adaptation Syndrome of Selye and the Phenomena of Reilly. P. Decourt.—p. 532.

Hydrazine of Isonicotinic Acid in Treatment of Tuberculosis. E. Sivrière. —p. 534.

Selye's General Adaptation Syndrome and Reilly's Phenomena. —Decourt calls attention to a report by J. Reilly and other French investigators in 1934 that was the first of a series on the role of the sympathetic nervous system in certain intestinal lesions, the first studies being made on typhoid patients. Subsequently these investigators showed the nonspecific character of this reaction and spoke of it as Reilly's phenomena. Decourt then shows that the reactions of the organism to which Selye applied the term "the general adaptation syndrome" are identical with Reilly's phenomena. These reactions are not the result of modifications of the adrenal cortex, as is maintained by Selye, but are, as Reilly and co-workers demonstrated, due to action on the sympathetic nervous system by the attacking agent. On the other hand, it has not been demonstrated how the initial lesion of the sympathetic nerve fibers provoke the nonspecific reactions in the peripheral cells. Reilly's school suggested the simultaneous action of several mechanisms: liberation of chemical mediators or toxic organic products, or direct trophic actions, and secondary endocrine reactions. The role of the adrenals in Reilly's phenomena will be discussed in a later report.

Circulatory Changes in Clubbing of Fingers and Toes.—Previous reports of increased blood flow through clubbed fingers were confirmed in cases of clubbing associated with cardiac and pulmonary disease. The increase in blood flow was not due to the action of vasodilator nerves. Two cases of unilateral clubbing due to arteriovenous fistulas are described. In one the fistula was in the distal part of the foot, and there was conspicuous unilateral clubbing of the toes. In the other a fistula was in the left index finger, which alone was clubbed. In both cases there was increased circulation in the affected digits. Evidence is presented that reduction in peripheral blood flow led to regression of clubbing, particularly in cases in which ligation of a subclavian artery caused asymmetry in the degree of finger clubbing. In clubbing associated with intrathoracic disease, successful surgical or medical treatment of the underlying condition led to a decrease in finger blood flow and gradual disappearance of the clubbing. It is believed that the blood flow to clubbed digits is in excess of physiological requirements, and largely passes through the numerous arteriovenous anastomoses in the distal segments. The direct passage of blood from digital arteries into the deep venous plexuses is held to account for the structural changes demonstrated in clubbed fingers. Comparison is made between such changes and those related to pathological arteriovenous fistulas in limbs. The superfluous blood flow in unilateral clubbing is thought to be due to physical abnormalities in the arterial tree. In bilateral clubbing it is probably a result of generalized circulatory disturbances.

Repair of Soft Parts in Orthopedic and Traumatological Surgery. L. Barros de Abreu.—p. 41.

Osteomyelitis Following Intramedullary Infusion in Infants.—Osteomyelitis of the tibia developed in 8 patients in a group receiving about 800 intramedullary infusions at the Hospital das Clinicas at São Paulo. Four of the patients with osteomyelitis recovered without after-effects during a 12 month follow-up period, two died, and two had serious residual disabilities. The intramedullary route should never be used for infusions in the presence of infection; osteomyelitis following intramedullary infusion may result in death or deformity. Destruction of the bone and epiphyses results in shortening of the affected limb, sometimes necessitating amputation. Intramedullary infusion should be resorted to only when no other method is feasible, and should always be carried out by a physician familiar with the problems involved. The needle should be withdrawn after each infusion; leaving it in place for a prolonged period is a frequent cause of infection. Another important precaution is immobilization of the limb to keep the needle from moving and to protect the puncture site from possible contamination. A small device for securing immobility of the needle is described by the authors.

Cancer of the Esophagus and Cardia. J. M. de Freitas, M. Ramos de Oliveira, E. B. Montenegro and H. Lotufo.—p. 133.
*Hormone Treatment of Varices of Pregnancy. C. Tortelly Costa and J. Pantaleão.—p. 185.

Hormone Treatment of Varices of Pregnancy.—Varices may develop during the last part of the first trimester of pregnancy, increasing rapidly in size until the beginning of the last trimester, when they seem to become stationary. They are localized mostly in the lower part of the body, especially the genitalia and the termination of the rectum, on the outer surface of the hips, and in the legs, and are usually bilateral. Pain caused by large serpentine varices may be so severe that the patient is unable to carry on her usual activities; small vessels dilated over a large area may cause discomfort and are unsightly. Varices are a frequent complication of pregnancy; they occurred in 1,060 of a series of 1,675 pregnant women studied by the authors. The high incidence in this series is attributed to factors such as probable hormone deficiency, the fact that the women lived in hill country and were obliged to carry heavy objects, such as buckets of water, and dietary deficiency. The weakening and relaxation of the walls of the veins that results in distention has been attributed to the presence of a hormone in the circulation, and various estrogens have been found useful in treating the condition. Benzoate of estradiol (progynon B® in oil) was used with good results by the authors, who report 37 typical cases; all 37 patients had severely painful varices and all experienced relief of pain; in 25 no further increase in the size of the vessels took place, and in 12 there was a diminution in size. Intolerance to the medication was not observed, and there were no complications, either during labor or the puerperium. Benzoate of estradiol may reduce lactation, and its use is not advised when labor is near. The newborn were not affected, and there were no cases of abortion.

*Piperoxan Test in Arterial Hypertension. E. May, Lamotte-Barrillon, R. Heyblon and C. Laville.—p. 1249.
Atypical Myeloma; Study of Roentgenologic, Cytological and Clinical Pecularities. G. Gelin.—p. 1256.
*Epidemiology and Prophylaxis of Poliomyelitis. J. Boyer.—p. 1263.

Piperoxan Test in Arterial Hypertension.—Piperoxan (2-[1-piperidylmethyl]-1,4-benzodioxan, or 933F), in doses of 0.25 mg. per kilogram of body weight in two minutes was injected in 55 patients (33 with essential hypertension, 14 with moderate or doubtful hypertension, and 8 with normal blood pressure). Except for mild tachycardia, restlessness, and anxiety, the test was well tolerated. The patients with essential hypertension showed a temporary rise in the arterial tension and pulse rate. The rise of the systolic blood pressure was characteristic, while that of the diastolic pressure was less constant. The increase in systolic pressure was greater in the patients with essential hypertension than in those with normal blood pressure, while intermediate results were observed in the patients with moderate or doubtful hypertension. Two patients who were given a subcutaneous injection of pentamethonium shortly before the intravenous injection of piperoxan did not respond to the latter drug with a rise of blood pressure. Blocking of vasomotor activity at the level of the autonomic ganglions by pentamethonium abolished the hypertensive effect of piperoxan. It was thus confirmed that piperoxan, besides being adrenolytic, exerts a direct effect on the nervous centers, particularly on the medulla oblongata. The rise of blood pressure is of central origin and is a manifestation of vasomotor hyperexcitability. The rise of blood pressure in response to the piperoxan test in patients with essential hypertension is in contrast to the lowering of blood pressure that occurs in patients with pheochromocytoma. Three patients without pheochromocytoma in the authors' series responded to piperoxan with a lowering of blood pressure. This was not pronounced and did not always occur on repeated tests. Functional, temporary, and insignificant hyperadrenalemia may be present in such cases. Patients with hypertension associated with menopause and with hyperthyroidism deserve to be studied from this point of view. With respect to the pathogenesis of hypertension, the piperoxan test is an aid in eliminating epinephrine and arterenol (nor-epinephrine) as important factors of essential hypertension. The fact that piperoxan causes lowering of blood pressure in dogs in which hypertension had been produced by section of the nerves of Cyon and Hering proves that failure of this depressor system is not responsible for essential hypertension.

Epidemiology and Prophylaxis of Poliomyelitis.—Results of epidemiological studies of poliomyelitis carried out by the author in France for the last 16 years do not support the classical view that poliomyelitis may be transmitted by the nasopharyngeal route, but rather support the modern concept that this disease is spread by contaminated water or food. In addition to milk and butter, green vegetables, such as lettuce, that may become contaminated by manure and soil may be sources of transmission. The war and occupation of France, with the exodus of the population in 1939-1940 and its return in 1944-1945, caused intermittent outbreaks of infectious diseases transmissible through the nasopharyngeal route, such as cerebrospinal meningitis, but did not produce an increased incidence of poliomyelitis despite the fact that these shifts in population occurred during summer and fall. In the Seine district, where, because of food deficiencies during the German occupation, people were eating much fresh lettuce, the disease occurred three or four times as often in the months of July to October as in January to June, in contrast to the usually observed ratio of 2 to 1. A curve plotting the incidence of poliomyelitis between 1943 and 1950 according to the age of the patients showed that 35% were preschool children, 20% were school children, 19% were adolescents, and 26% were adults. The highest incidence of the disease may be observed at the age of 2 years because few infants have antibodies in their serum at this age, while at the age of 4 years two-thirds of the children may have acquired antibodies by an inapparent infection. Paralytic complications occur only in a small number of patients. In countries in which poliomyelitis is common the acute form is rare, because the inapparent infections occur early. It is fortunate, however, that they usually occur before the child loses all the immunity acquired from the mother in utero. On the contrary, in countries in which poliomyelitis is rare the severe acute form prevails. Thus the author concludes that, as sanitation improves, the virus becomes rarer, immunity to poliomyelitis is acquired later, and morbidity and mortality rates are increased.

*Ehlers-Danlos Syndrome: Description of Three Cases in Severely Affected Family. K. O. Husebye.—p. 185.
Mitral Stenosis—Lung Tumor: Report on Clinical Method of Examination. H. Rasmussen.—p. 189.
Radioactive Iodine and Induction of Cancer. L. Kreyberg.—p. 190.
Sino-Bronchial Syndrome. J. Dedichen.—p. 192.

Familial Danlos' Syndrome.—The cases of Danlos' syndrome reported by Husebye occurred in twin brothers and an uncle. The administration of 110 mg. of corticotropin (ACTH) in divided doses over a four day period in one case had no effect on the symptoms. Five additional cases of the syndrome in the family are mentioned. In all, four generations are represented. The disorder is believed to be transmitted by an autosomal dominant factor. Persons with this syndrome should avoid traumas, and should have careful local and general treatment following injury.

BOOK REVIEWS

Advances in Pediatrics. Volume V. Editor: S. Z. Levine. Associate editors: Allan M. Butler, Margaret Dann, L. Emmett Holt, Jr. and A. Ashley Weech. Cloth. $7. Pp. 273, with illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1952.

It is fortunate that the editorial staff of this book decided to resume its publication. The high quality of the authoritative articles that has marked this publication in the past continues in this edition. The articles note and evaluate the contributions made by past and present workers. These contributions, recorded in an orderly fashion, summarize the present state of knowledge concerning pediatrics. The authors then discuss their conclusions and the conclusions held by contemporary workers. This manner of presentation is valuable, because it fills a void in medical literature. Few physicians can profitably peruse the large number of articles written about any medical topic, yet many physicians are not satisfied with the necessarily condensed and didactic discussions found in standard textbooks.

The complete bibliographies increase the value of the book as a source of reference for the medical literature concerning the subjects discussed. By the selection of authoritative contributors and topics of current interest, this edition continues to fill a noteworthy position in pediatric literature.

Modern Practice in Tuberculosis. Volumes I and II. Edited by T. Holmes Sellors, M.A., D.M., M.Ch., Thoracic Surgeon, Middlesex Hospital, and J. L. Livingstone, M.D., F.R.C.P., Physician, King's College Hospital and Brompton Hospital, London. Cloth. $27.50 per set. Pp. 355, with 104 illustrations; 441, with 159 illustrations. Butterworth & Co., Ltd., 4-6 Bell Yard, Temple Bar, London, W.C.2; distributors in U. S. A., Paul B. Hoeber, Inc., 49 E. 33rd St., New York 16, 1952.

The editors of this two volume text, surgeon and internist, respectively, in the field of chest diseases and both well-known practitioners in leading London hospitals, have brought together as contributors a majority of the chief authorities on tuberculosis in the United Kingdom. Their purpose, as indicated in the preface, is to furnish a broad picture of medical practice in the field, by inviting recognized experts to present their opinions in their own way without the requirement of conformity to a single pattern of thought. The result is a fairly well-balanced collection of monographs on both fundamental and practical aspects of the treatment of tuberculosis. The late S. Roodhouse Gloyne, formerly consulting pathologist to the London Chest Hospital, sets the stage with a scholarly introduction, stressing the rapidity of modern progress, pointing out that recent advances in understanding have brought together the biochemist, the immunologist, the physician, and the surgeon, with new bacteriological controls. The 39 chapters include treatises on resistance to tuberculosis, vital statistics, the bacteriology and morbid anatomy of the disease, methods of rehabilitation, industrial aspects, diagnosis, prevention, and medical and surgical treatment.

The order in which the chapters appear is somewhat puzzling; in volume I, at least, no planned sequence is evident. This is of little moment, however, as the book will be used as a reference for critical consideration of separate fields rather than as a text for systematic instruction. The reader interested in methods of prevention will naturally turn to the chapters on BCG vaccination and mass x-ray examinations, the student of social problems to those on rehabilitation, psychology of the patient, and tuberculosis in industry, the internist to the monographs on diagnosis and chemotherapy, and the surgeon to the many separate chapters on surgical procedures, advances in excisional therapy, and the treatment of tuberculosis in various organ systems. Each will be rewarded, for the subject is presented in each case by an expert with a background of personal experience. Special tribute must be paid to the surgical chapters. The illustrations are excellent, and the reproductions of roentgenograms, e. g., in the chapter on empyema, are of surpassing quality. The book is heartily recommended as an up-to-date treatise on tuberculosis.

Angewandte Paediatrie: Ein Nachschlag- und Lesebuch für Studierende und Ärzte. Von. Dr. med. et phil. E. Mayerhofer, o. ö. Professor der Kinderheilkunde und Vorstand der Universitätskinderklinik in Zagreb. Cloth. 85 marks. Pp. 813, with 209 illustrations. Wilhelm Maudrich, Spitalgasse 1B, Wien IX/2, 1952.

This is an unusual book, if it is regarded as a conventional pediatric textbook. Its title as well as its subtitle are misleading, since it offers little that would be helpful to medical students. The author, who has been head of a children's clinic in Zagreb, Jugoslavia, for nearly 30 years, wrote this book as a résumé of his life's work.

What seems most unusual is the emphasis on subjects that are generally considered of minor importance in the United States; for example, there are 77 pages dedicated to the discussion of climatotherapy, baths, spas, and related subjects. There are seven pages on diseases of the navel in newborn infants; yet, common diseases of clinical importance, such as acute nephritis and rheumatic fever, receive little attention. The subject matter is arranged according to age groups rather than body systems; this makes it difficult to look up concise information about a given disease. As a pupil of Pirquet's, the author understandably puts much emphasis on allergy. He regards such entities as pyloric spasms, melena neonatorum, and even hydrocele of the newborn as allergic manifestations.

Much of what the author advocates concerning infant feeding is in sharp contrast to modern American concepts. Foods are introduced into the diet late, and methods of formula calculation are complicated. Therapy often seems outmoded as, for example, the advice to administer serum to children with scarlet fever, "even in mild cases."

The illustrations are poor, and the bibliography contains references that are almost exclusively written in German. This book is of interest mainly to pediatricians who would like to get some insight into European pediatric thinking.

A Textbook of Pharmacology: Principles and Application of Pharmacology to the Practice of Medicine. By William T. Salter, M.D., Professor of Pharmacology, Yale University School of Medicine, New Haven. Cloth. $15. Pp. 1240, with 284 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1952.

The author has attempted to write a comprehensive textbook for "the medical student and the up-to-date practitioner" wherein the examples cited "in evidence of fundamental statements are selected from material which has a clinical bearing."

The author's choice of apt quotations for each chapter superscription is original, and it is well worth the time spent in browsing through the book to read these quotes alone. Unfortunately, the text is not as concise as the quotations. One factor accounting for this is the attempt to discuss subjects such as antibiotics in a general way instead of discussing each antibiotic in detail. A rigid framework of paragraph headings has been scrupulously followed; this frequently sacrifices the reader's interest and results in needless duplication. Because the manuscript was not revised, some errors can be found, such as on page 1,043: "By the time this book is published, probably the second of these, i. e., sulfapyridine, will have been discarded to a considerable extent"; (sulfapyridine was discarded by 1943). On page 1,042 the author states: "It still remains for chemotherapy to take the field against the rickettsial type of infection," yet on page 1,049 he writes: "Why it [PABA] should be effective in typhus fever remains undetermined." In later pages chloramphenicol, aureomycin, and terramycin are all admitted to be effective against rickettsial infections. Certain chapters, such as those on cardiac drugs, anticonvulsants, and hormones, are outstanding. Other chapters, such as those on anesthesia, curare, and chemotherapy are less than average; however, although the book may be slightly inconsistent, it is readable and is the most up-to-date comprehensive text on pharmacology available.

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

The Chemistry and Technology of Food and Food Products in Three Volumes. Volume III. Prepared by group of specialists under editorship of Morris B. Jacobs, Ph.D., Adjunct Professor of Chemical Engineering (Food, Flavor, and Dairy Technology), Polytechnic Institute of Brooklyn, Brooklyn, N. Y. Second edition. Cloth. $15. Pp. 1773-2580, with illustrations. Interscience Publishers, Inc., 250 Fifth Ave., New York 1; 2a Southampton Row, London, W.C.1, 1951.

The third and concluding volume of this series of excellent articles on the different aspects of the chemistry and technology of foods discusses the various commercial methods of food preservation and describes the processing of common foods. Dehydration, temperature control, the use of hermetically sealed containers, the use of micro-organisms, and the use of chemical preservatives are discussed with enough detail to give the uninformed reader an idea of the varied problems encountered in the industry. A concise chapter on the why and the wherefore of packaging ends the first part of the book.

The last section, dealing with the processing of common foods, will prove extremely interesting to those desiring a general picture of the actual methods used in manufacturing cereals, breads, sugars, confectionery, fruit juices, milk and milk products, meat, oils and fats, and beverages. Each chapter is written by an authority familiar with the food in question. The material in this last part tends to overlap the subject matter in part 4, which describes the various food groups; however, this overlapping has been kept to a minimum and is not objectionable, since it is used only to maintain the continuity of a chapter. An important aspect of this series of articles is the stress placed on the role played by adequate nutrition in modern life. The physician and dietician will especially appreciate this, since few books concerned with the technology of foods emphasize the subject of nutrition.

Differentialdiagnostische Symptomatologie von Krankheiten des Kindesalters: Klinische Vorlesungen. Von Professor Dr. med. Werner Catel, Chefarzt der Landeskinderheilstätte, Mammolshöhe/Taunus. Second edition. Cloth. 69 marks. Pp. 640, with 222 illustrations. Georg Thieme, Diemershaldenstrasse 47, (14a) Stuttgart O; agents for U. S. A., Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1951.

The author has selected a single symptom as the topic of each chapter. The diseases that might cause or contribute to this symptom are then discussed within the framework of each respective chapter. The author is concerned with enumerating and classifying the diseases responsible for a given symptom rather than with distinguishing one disease from another. Each disease is thus described as an entity. The following symptoms are discussed: dwarfism, cranial deformities, hypertension, hypotension, cardiac arrhythmia, anemia, polycythemia, skin and mucous membrane hemorrhage, cervical lymph node enlargement, vomiting, abdominal pain, jaundice, paralysis, and spasm.

In the last 50 years, books on pediatrics or internal medicine, including those on differential diagnosis, have lost contact with diagnostic medicine as it is actually practiced to an ever increasing degree. The use of laboratory tests, radiological consultations, health surveys, preventive measures, improved record keeping, and standardized nutrition have narrowed down the choice of diagnoses in a given case to such a degree that the correct diagnosis is made in most instances without the ponderous weighing of classical clinic signs and before the disease has unfolded itself to such an extent as to match its classical description. This book represents a commendable reversal of this trend. Its author has succeeded better than most of his predecessors in eliminating the so-called classic description of diseases by omitting antiquated diagnostic signs and by avoiding a chronological description of the course of diseases. In short, the discussion of diseases in this book stands closer to medicine as it is practiced today in a well-equipped hospital than will be found in most other books. This has been accomplished by the inclusion of an exceptionally large number of radiographs, most of which are technically adequate. Their interpretation by the author is generally correct except when it refers to controversial material as is the case in discussing some chondrodystrophies. The author circumvents the necessity of covering the entire field of pediatrics by giving his book the subtitle of "clinical lectures" and by pointing out in his preface that only a segment of pediatrics is dealt with "thus far," implying that future editions might be more complete.

The discussion of neurological diseases could have been improved by omitting a detailed description of normal and abnormal response of muscle to faradic and galvanic stimulation, which is nowadays of little diagnostic value. A tendency to subdivide disease entities beyond the logical limit distracts from this chapter as well as from the discussion of skeletal anomalies. The severest criticism of the book is that the bibliography contains German and Swiss references almost exclusively. This is reflected in the text by the briefness with which non-German, particularly Anglo-American, contributions to pediatrics are treated. Cystic fibrosis of the pancreas and sickle cell anemia occupy only a small paragraph, and the discussion of celiac disease is disproportionately short. There is no discussion of the recently investigated specific properties of prenatal and neonatal hemoglobin, although the chapter on blood diseases is extremely long. Electrocardiography is extensively discussed, but the existence of a fourth or fifth electrode is nowhere mentioned. A single page is dedicated to the discussion of congenital anomalies of the heart and confined to their electrocardiographic manifestations. It seems that the author is unaware of the present status of heart surgery in the United States and the need for a more accurate differential diagnosis of congenital heart lesions. He also appears to be unfamiliar with some of the modern theories on calcium metabolism. Though he is familiar with Fuller Albright's work, he quotes only Fanconi in his bibliography. He emphasizes the importance of citric acid for adequate calcium resorption and finds cow's milk inadequate in this respect. He ascribes relative antirachitic properties to mother's milk, because it contains the optimal ratio between calcium ions and citric acid radicals. This viewpoint is not generally accepted in the United States. One gains the impression that the author is a German nationalist who endeavored above all to represent the neo-German school of pediatrics from 1936 to 1950. Though this might not be objectionable to the American reader who has other sources of information at his disposal, it is probably detrimental to German pediatricians, because it isolates them further from Western thinking.

Despite these shortcomings, this book will probably gain a permanent place in pediatric literature because of its original approach and its literary unity, which is the result of single authorship. Its usefulness is limited to those pediatricians who are teachers and desire to stimulate or lead intelligent ward round discussions. The quality of paper, print, and illustrations is excellent.

The Isocortex of Man. By Percival Bailey and Gerhardt von Bonin. Illinois monographs in medical sciences, vol. VI, nos. 1, 2. Paper. $5. Pp. 301, with 136 illustrations. University of Illinois Press, 358 Administration Building, Urbana, Ill., 1951.

The immediate reason why the authors decided to embark on this investigation of the human cerebral cortex lies in their previous work on the macaque and chimpanzee. These previous studies were undertaken to lend precision to the results of physiological neuronography performed on these primates and was to be applied, it was hoped, to man. In the course of their studies, it became clear that the precise homology of which they had dreamed could be achieved only when maps of all three primates, man, chimpanzee, and macaque, had been drawn by the same observers.

The authors also point out that contrary to the commonly accepted idea the number of brains that have been adequately studied from the cytoarchitectonic viewpoint is small. In addition, some of the reports in the literature are based on the study of brains that were removed several to many hours after death and not properly fixed.

The monograph is divided into nine chapters. The longest, chapter 5, is concerned with the description of serial sections cut from 21 blocks that together comprised one whole hemisphere of a young, healthy adult who died of an accident without injury to the head. The brain was removed within one hour after death after perfusion through the arteries with a 4% aqueous solution of formaldehyde. Study of Nissl preparations was supplemented by the examination of silver impregnations and preparations stained for myelin.

From their study, the authors recognize two distinct types of cortical architecture, the allocortex and the isocortex and four variants of the latter: eulaminate, agranular, koniose, and limitrophic. These are discussed fully in chapter 4.

The brain map is discussed in more detail in chapter 6. The authors stress the fact that vast areas of the cortex are so closely similar in structure as to make any attempt at subdivision unprofitable, if not impossible, and that the drawing of sharp areal boundaries, on the basis of many structural peculiarities of varying distinctiveness and significance, is the fundamental defect of most maps and has been carried to absurd lengths by the Vogt school.

Other chapters deal with growth and weight of the brain, fissures of the brain, intercortical connections, afferent and efferent connections, and functional significance. In addition, there is an historic introduction, a bibliography, and plates illustrating 15 different regions, which, from the architecture of the cortical cells, can be readily recognized. Throughout the monograph, there is a critical discussion of previous work on the subject. Many of the 121 figures are reproduced from other authors' works in order to clarify this discussion.

The book is well printed, the figures and plates well reproduced, and the style clear and readable. The simplified cortical map that is related to functional activity will be gratefully received by the many neurologists and neurophysiologists who have difficulty in recognizing the minute differences between the numerous areas of the cortex described by other authors and who can see no useful purpose in excessive parceling of the brain.

An Atlas of General Affections of the Skeleton. By Sir Thomas Fairbank, D.S.O., O.B.E., M.S., Consulting Orthopaedic Surgeon, King's College Hospital, London. Cloth. $10. Pp. 411, with 510 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1951.

In this book, about 80 skeletal disorders that typically involve more than one bone of the skeleton are clearly and concisely discussed. This is a reference book for diagnosis, and, as such, it will be a valuable addition to the library of all orthopedic surgeons.

The technical publication of the book is excellent, and the illustrations are clear and diagnostic. The sections on the dysplasias of bone and cartilage growth are exceptionally complete and informative. Although a few good microscopic illustrations are included, the value of the book would be enhanced with more discussion of pathology with accompanying illustrations. There are occasional statements in the book that are not in agreement with most American authors. An example of this is the following statement: "As a help in diagnosis, alkaline phosphatase estimations are disappointing, and are practically useless." This viewpoint is not accepted in the United States. The author makes the statement that the alkaline phosphatase is raised in all conditions in which there is hypocalcification or osteoporosis. This statement is not substantiated by clinical experience. The author discusses aseptic necrosis of bone in a logical manner, although his conclusions are open to argument.

The 62 chapters of this book include discussions of most of the idiopathic, congenital, endocrine, hereditary, and neoplastic diseases of the skeleton. It is recommended as a reference book to all physicians engaged in the diagnosis and treatment of skeletal disease.

Leonardo da Vinci on Movement of the Heart and Blood. By K. D. Keele, M.D., F.R.C.P. With foreword by Charles Singer, M.D., F.R.C.P. Limited edition. Cloth. $15. Pp. 142, with 69 illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, [n.d.].

Any work about Leonardo da Vinci, the almost fabulous man of science, should intrigue the intelligent reader and stimulate his curiosity. On reading this book, one will have renewed admiration for the genius of Leonardo and will be grateful for the skillful manner in which the author guides the reader through the maze of Leonardo's anatomic work.

The author sketches Leonardo's importance as an artist, a physicist, and an engineer but does not attempt to describe all of Leonardo's achievements in the field of anatomy. He confines his attention to Leonardo's anatomic work on the heart and blood vessels, pointing out his mistakes as well as his achievements. Leonardo, an accurate observer in most instances, was, however, so steeped in the anatomic teachings of Galen and Avicenna that he described septal pores in the heart and represented the right pulmonary veins as entering the right auricle. On the other hand, his illustrations and descriptions of the heart valves, both in systole and diastole, of the coronary arteries, of the atria, of the sinuses, later named by Valsalva, and of the moderator bond are accurate and surprisingly vivid.

Of absorbing interest are the physiological studies on the heart and circulation made by Leonardo. He describes and illustrates the action and function of the heart valves, the myocardium, the pulmonary vessels, and the veins. Although he accepts the fundamental theses of Galenic physiology, Leonardo often disagrees with Galen and views the body entirely from the mechanistic point of view.

Dr. Keele's work is written with charm and clarity. Although he stresses Leonardo's greatness, he also points out his limitations as a child of his century. The book is excellently illustrated, beautifully printed, and takes its place as an important addition to the subject of Leonardo's anatomic researches.

Die Hormone. Von Dr. med. Rudolf Abderhalden, Dozent für Physiologie und Pathologie der Hormone, Vitamine und Fermente an der Universität Basel. Lehrbuch der Physiologie in zusammenhängenden Einzeldarstellungen. Unter Mitarbeit einer Reihe von Fachmännern, herausgegeben von Wilhelm Trendelenburg und Erich Schütz. Cloth. 29.70 marks. Pp. 203, with 46 illustrations. Springer-Verlag, Reichpietschufer 20, Berlin W. 35 (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Göttingen, 1952.

This small monograph is one of a series comprising a textbook of physiology. It makes no attempt to cover the entire subject, as it omits all anatomic considerations and refers only in passing to the clinical aspects of the subject. After a brief introductory consideration of the general principles underlying endocrine activity, each of the hormones is considered consecutively, with special emphasis on their chemical structure and physiological action. The material is sound and up-to-date but lacks coordination and critical evaluation. This is also reflected in the 700 references appended to the text. In general, this monograph may be recommended to the physiologist, for whom it was primarily written, but it will be of little interest to the clinician and student of endocrinology.

Etiology and Diagnosis in the Treatment of Infertility in Men. By Robert S. Hotchkiss, M.D., Professor and Chairman, Department of Urology, New York University, New York. Publication number 53, American Lecture Series, monograph in American Lectures in Endocrinology. Edited by Willard O. Thompson, M.D., Clinical Professor of Medicine, University of Illinois College of Medcine, Chicago. Cloth. $2.50. Pp. 73, with 15 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, 1952.

The information in this monograph is taken largely from the author's extensive experience and research in the field of male infertility. In general, the book is well written and concise. The illustrations are of good quality, and the type is excellent for quick reading. The recognized methods and procedures for evaluating male infertility are discussed in a well-organized form. In addition, there is a brief discussion of the embryologic features of the reproduction tract and the interrelation of the endocrine system. The book can be especially recommended to the busy practitioner who wishes a short, up-to-date treatise on male infertility.

Diseases of the Nose, Throat and Ear: A Handbook for Students and Practitioners. By I. Simson Hall, M.B., Ch.B., F.R.C.P.E., Surgeon to Royal Infirmary, Edinburgh. Fifth edition. Cloth. $4. Pp. 463, with 90 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1952.

This edition of a popular English handbook on diseases of the nose, throat, and ear is directed to meet the needs of general practitioners and medical students. In this revision, the author has introduced proved, acceptable methods of therapy but has avoided discussing controversial topics.

QUERIES AND MINOR NOTES

KIDNEY FUNCTION TESTS

To the Editor:—*Other than concentration tests are there any kidney function tests like the liver function tests that will aid in diagnosis? In other words, is one kidney function test sufficient, or is more than one required, each testing a separate function?* *F. D. Cook, M.D., Menomonie, Wis.*

Answer.—The kidney, like the liver, performs many functions, some even that are unrelated to the formation and excretion of urine. For the most part, the clinical tests of renal function serve as a means of quantitative diagnosis of the degree of functional impairment. Qualitative diagnosis of the nature of the renal disease is ordinarily made from other clinical data but may be derived, in part, from the use of the specialized clearance techniques in which glomerular and tubular functions can be separately measured and their interrelations as well as their relations to renal blood flow determined. Unfortunately, these procedures are not practical except in institutions equipped with research laboratories and experienced personnel.

For ordinary clinical purposes, the most useful tests for kidney function are the test for maximal concentrating ability, which measures over-all tubular function, and the urea clearance test, which is a fair index of glomerular filtration. In advanced stages of renal disease, when acidosis and other electrolyte disturbances dominate the clinical picture, serum electrolyte determinations for sodium, potassium, chlorine, carbon dioxide, phosphorus, and calcium assume priority over other tests for renal function as a guide to treatment. In the nephrotic syndrome, quantitative measurement of urinary protein output and of the serum protein and lipid fractions can be helpful in diagnosis and treatment.

In rare types of renal disease, such as the Fanconi syndrome, hyperparathyroidism, and osteomalacia caused by the inability of the renal tubules to make ammonia, special serum and urine electrolyte studies may be the only means of making a diagnosis. It must never be forgotten that pyelographic examination is also a renal diagnostic aid of major value when used properly. Careful study of the urinary sediment is another important aid, although it is often neglected. In short, routine studies of kidney function are best performed after considering the individual clinical problem and selecting the tests adequate to furnish the information desired.

POISONOUS FISH

To the Editor:—*I have read that certain fresh fish are poisonous, especially tropical varieties. Is there any way to determine which fish are poisonous? What is the cause of the so-called poisoning? Is any treatment of value for such disturbances, which I understand are primarily gastrointestinal in nature?* *Edwin Pyle, M.D., Waterbury, Conn.*

Answer.—Ichthyosarcotoxism is a distinct clinical entity resulting from ingestion of poisonous fish flesh. The results of studies seem to indicate that these toxins are not bacterial in origin. Hence, putrefaction does not play a significant role in the production of the disease. Whether the toxin is a poisonous alkaloid or some closely related substance is not known. The disease is largely confined to tropical but widely scattered areas such as the Virgin, Marshall, and Mariana Islands. Many tropical marine fishes that are considered to be valuable commercial species in one area, e. g., red snapper, rockcod, seabass, and crevally, may be violently toxic in another. The number of poisonous fishes and their distribution is unknown; moreover, there is no simple test available at present for determining their edibility. The most reliable methods involve the preparation of tissue extracts, which are injected intraperitoneally into mice, or feeding samples of the viscera and flesh to dogs or cats. The test animal should be observed for a minimum of 24 hours for the appearance of gastrointestinal and neurological symptoms. Some of the earliest symptoms to appear in animals are vomiting, hypersalivation, and ataxia. In severe cases, the ataxia will be followed by convulsions, paralysis of the limbs, respiratory paralysis, and death. Numerous theories have been propounded on the cause of fish poisoning, but none have been supported by solid scientific evidence. The majority of ichthyologists believe the answer will be found in the food chain of these fishes.

The disease is characterized by symptoms of diarrhea, nausea, vomiting, and abdominal pain, which usually occur within three to six hours after ingestion of the fish. Gastrointestinal symptoms may be accompanied or followed later by sensations of tingling of the mouth, tongue, lips, face, hands, and feet. About 50% of these patients complain of difficulty in determining the temperatures of liquids either when taken by mouth or on the external surface of the skin. Hot objects are sometimes interpreted as feeling cold and cold objects hot. In addition there may be other types of sensory and muscular disturbances which may be bizarre in their manifestations. Extreme weakness and muscular paralysis are common. The mortality rate is said to be about 1 to 2%. The treatment is symptomatic, since there is no known specific antidote. The reader is referred to Khlentzos's article (*Am. J. Trop. Med.* **30**:785-793, 1950) for a more complete discussion on the treatment of fish poisoning. An attack of ichthyosarcotoxism does not impart immunity.

GENITAL TUBERCULOSIS

To the Editor:—*A married European woman, aged 30, has genital tuberculosis, as demonstrated by repeated biopsies of the endometrium during 1950. A year ago she was treated with streptomycin, 1 gm. daily for 60 days, simultaneously with para-aminosalicylic acid, 10 gm. daily for 50 days. During the past year, following treatment, three biopsies were negative for tuberculosis. A hysterogram taken with low pressure of the contrast medium showed bilateral pyosalpinx or hydrosalpinx at the ampullar sections of the fallopian tubes. The remainder of each tube is permeable and not dilated but seems irregular and knotted. The patient feels well and desires pregnancy. She will begin a trip to the United States and Europe in two months. 1. Should an operation be performed before she makes her trip? 2. Is radical removal of the fallopian tubes necessary? 3. If the radical operation is advisable, is there any chance that the patient would achieve normal pregnancy if a plastic operation were done? 4. What kind of plastic operation would you suggest? 5. Does any inconvenience or danger of complications, such as extrauterine pregnancy, abortion, necrosis, or postoperative adhesions, result after such a plastic operation? 6. What safety measures, such as antibiotic therapy, short wave diathermy, and contraceptives, should be applied before, during, and after the operation.* *M.D., Chile.*

Answer.—The fact that recent endometrial biopsies done one year after streptomycin therapy have shown no evidence of an endometrial lesion cannot be interpreted as indicating that there has been a cure of tubal tuberculosis, which has almost surely been present also. What little evidence is as yet available on the results of streptomycin therapy in genital tuberculosis seems to be strongly against such an assumption. Gynecologists are anything but enthusiastic about the results of tubal plastic procedures, even for nontuberculous salpingitis. It is difficult to believe that anyone would recommend these measures for the tuberculous variety, in the presence of which pregnancy is notoriously rare, not merely because of the frequency with which occlusion occurs but also because of the diseased tubal wall and

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

consequent impairment of its physiological function. This would apply whether the procedure involved is salpingostomy, tubal resection and tubouterine implantation, or cornual ovarian implantation.

1. There would be little or no hazard in a delay of two months or in the "strain" of a sea voyage, which is often relaxing and restful. 2. Radical removal of the fallopian tubes is, in general, the accepted and the soundest procedure for tubal tuberculosis. 3. Only a slim possibility of normal pregnancy would result from cornual implantation of the ovaries, which can usually be safely conserved. The prospects for pregnancy after any such plastic operation are very poor, especially in a patient having tuberculous disease. 4. The choice of plastic operations to be done must be based on the operative findings and would involve supplementary use of such procedures as reverse insufflation. 5. There is danger of the complications mentioned. 6. In regard to necessary safety measures, the normality of the husband should be established and the possibility of pulmonary tuberculosis in the wife excluded. Postoperative insufflations are indicated in the case of tubal plastic operations; other details of preoperative and postoperative care should be left to the surgeon.

HYPERTENSION, CIGARETTES, AND CAFFEINE

To the Editor:—*During the last few months, I have checked some R. O. T. C. boys for hypertension. Without exception, so far, all those with hypertension have shown normal blood pressure about 48 hours after they discontinued smoking cigarettes and drinking coffee and cola drinks. At the same time psychotherapy has been administered. Will you please comment on the foregoing?*

H. D. White, M.D., Dallas, Texas.

Answer.—It seems probable that cigarettes, coffee, and cola drinks have a greater pressor action in prehypertensive and hypertensive subjects than in normotensive ones. It is from the group of prehypertensive that the truly hypertensive patients are drawn. This problem is discussed by Page and Corcoran (Arterial Hypertension: Its Diagnosis and Treatment, ed. 2, Chicago, The Year Book Publishers, Inc., 1949). Nicotine is well known to have a pressor effect in many but not in all patients. Whether only the prehypertensives show an abnormally great response has not been determined. Roth has discussed in some detail this part of the problem in her recent monograph (Tobacco and the Cardiovascular System, The Effects of Smoking and of Nicotine on Normal Persons, American Lecture Series, Publication 100, Springfield, Ill., Charles C Thomas, Publisher, 1951). Caffeine in moderate doses has little effect on arterial pressure but in excessive amounts, by overstimulating the brain, leads to a prolonged slight rise in blood pressure. Obviously many youngsters greatly abuse smoking, and drinking of coffee and cola containing beverages. Those with hypertensive propensities should probably avoid them.

YAWNING

To the Editor:—*Why is a yawn "catching?"*

Edward Dengrove, M.D., Asbury Park, N. J.

Answer.—Yawning may be considered to be a form of inspiration tic, associated with dyspnea. P. Janet describes yawning as related to sighing, sobbing, and hiccoughing, and refers to it as an example of "imitative contagion" (The Major Symptoms of Hysteria, New York, The Macmillan Company, 1907, p. 259). It is a complex nervous respiratory reflex associated with mild boredom, irritating mental effort, or mild emotional anxiety. It is classified by R. Burton-Opitz (A Textbook of Physiology: For Students and Practitioners of Medicine, Philadelphia, W. B. Saunders Company, 1920, pp. 592-593) among the association or perception reflexes. These "skirt the realm of volition without being actually influenced by it and may be invoked in us in consequence of a visual impression of some one else already engaged in the act." Yawning is catching as a conditioned visual reflex when persons in a group are subjected to the same general boring or frustrating environment.

PHYSICAL RISK WITH ONE KIDNEY

To the Editor:—*A 30-year-old white man has been in good health all his life. While in military service during World War II, his right kidney was removed following trauma (concussion). He is now in good health and able to work and is active in softball and bowling. Yearly physical examinations show him to be normal. I would like your opinion concerning the physical risk to this patient resulting from the removal of one kidney, as there is a difference of opinion on this point.*

A. J. Wagner, M.D., Tucson, Ariz.

Answer.—Several papers have been written on the subject of longevity in persons with only one kidney. One of the most informative papers on this subject is that by the late Dr. Herman Kretschmer (*J. A. M. A.* **121**:473-478 [Feb. 13] 1943). Judging from his data, it is evident that life expectancy of such persons is about the same as that of persons with two kidneys, providing the remaining kidney is normal. To establish the fact that the one kidney is normal not only would necessitate the usual physical examination but would require special studies including a thorough, carefully done urinalysis, studies of renal function, and pyelographic examination. After such a complete study is made, it would be safe to assure the patient with one kidney that there is no physical risk involved in carrying on the usual types of work or play.

INFECTION OF LINGUAL TONSIL

To the Editor:—*A 35-year-old woman has recurrent attacks of a purulent infection of the lingual tonsil. These infections run a violent course causing a high temperature, and last for about one week. They do not respond to treatment with antibiotics and sulfonamides. This patient does not have tonsils or lymphoid tissue in the throat or nasopharynx. Her lingual tonsil is hypertrophic. Since surgical treatment is not intended, what results could be expected from treatment with roentgen irradiation?*

M.D., Ohio.

Answer.—The efficacy of roentgen irradiation in treatment of infected lingual tonsils is questionable. Application of a 10% solution of silver nitrate directly to the lingual tonsils once daily for several days may have a beneficial effect. Electrosurgical reduction of hypertrophied lingual tonsils should be attempted if mild cauterization proves inadequate.

FALSE POSITIVE SEROLOGIC TEST FOR SYPHILIS

To the Editor:—*A 33-year-old white man took an insurance examination, which was negative, except that on one of several examinations the left pupil was slightly smaller than the right. Two Kahn tests, taken at a two week interval, were 4+. The man gave a history of having had a 4+ serologic reaction 13 years before. At that time he received neoarsphenamine for three weeks, which produced nausea, vomiting, and headache. Four years later, he had a 4+ reaction, and a recheck showed a 2+ reaction. He then received penicillin injections five times daily for 10 days. Tests taken a week later and others taken several months afterward were still 4+. His father has a negative serologic test. His deceased mother had two miscarriages followed by four normal births. The patient's three siblings have negative tests. This man denies any possible contact other than his wife, who also has a negative serologic reaction. His spinal fluid Wassermann is negative, and his colloidal gold test reaction is normal. What is the consensus regarding "Wassermann-fast" persons? Does he have syphilis, and should he be turned down as an insurance risk? What treatment is recommended?*

M.D., Arizona.

Answer.—This is the sort of situation in which the physician should suspect that the patient in question does not have syphilis but does have a biologic false positive serologic test. The factors that prompt this suspicion are the absence of any known exposure to syphilis, the absence of a history of infection, a normal physical examination, normal spinal fluid, and negative epidemiological investigations of parents, siblings, and wife. The probability of biologic false positivity is not ruled out by the fact that the patient's blood serologic test has been known to be positive for 13 years.

The differentiation between syphilis and the biologic false positive phenomenon can be made by means of the newly developed treponemal immobilization test (Mohr, C. F.; Moore, J. E.; Nelson, R. A., and Hill, J. H.: Studies on the Relationship of Treponemal Antibody to Probable Biologic False Positive Serologic Tests for Syphilis, *Am. J. Syph.* **34**: 405 [Sept.] 1950.) This test for treponemal antibody is valid in spite of the fact that the patient has been treated for syphilis.

If the treponemal immobilization test is negative, it may be assumed that the patient does not have syphilis. In that case, the question arises: "Why does he have a biologic false positive serologic test?" This problem can be solved only by a fairly elaborate clinical and laboratory survey of the patient and perhaps by follow-up examinations repeated over a period of years. If the patient does have syphilis (the treponemal immobilization test being positive), no treatment is recommended. The question of seroresistance is discussed both from the standpoint of the physician and the patient by J. E. Moore (Seroresistance [Wassermann-Fastness] in Syphilis: A Discussion for the Patient, *Am. J. Syph., Gonor. & Ven. Dis.* **30**: 125 [March] 1946).

The eligibility of the patient for life insurance, assuming that he has syphilis, is likewise discussed by Schamberg and Moore (The Eligibility of Syphilitic Persons for Life Insurance, *J. A. M. A.* **134**: 1532 [Aug. 30] 1947).

HOT FLUSHES

To the Editor:—*A married woman, aged 28, complains of hot flushes occurring midway between her menstrual periods. She experiences some 6 to 10 episodes in 24 to 48 hours, each lasting about 10 to 20 minutes. Her menses are normal and regular. She has two children. Several days after she delivered her first baby she had eclampsia. She has had one ovary removed. Pelvic examination reveals no abnormalities. This woman, according to her mother, seems to have undergone some mental change since her eclamptic state four years ago and is despondent and worried about her condition. What treatment do you suggest?* *M.D., South Carolina.*

Answer.—It is unlikely that the hot flushes of which this woman complains are associated with her ovarian function. Hot flushes are usually the result of waning or complete cessation of ovarian function associated with the climacteric. Undoubtedly, her vasomotor symptoms have a psychosomatic origin and are related to her nervous state. Therapy should be directed at an understanding of her emotional difficulties and their eradication. Mild sedatives, such as phenobarbital, are helpful. Hormone therapy is not indicated.

CORTICOTROPIN AND RH-NEGATIVE MOTHER

To the Editor:—*I understand that corticotropin (ACTH) will produce changes in agglutination and sensitivities that will change positive results of a Coombs' test to negative results. Has any work been done on the use of corticotropin in Rh-negative mothers with multiple pregnancies? Would an Rh-negative patient with a high titer count and a positive Coombs' test reaction be helped by a series of treatments with corticotropin in the latter months of pregnancy?*

Ardow Ameduri, M.D., Utica, N. Y.

Answer.—No convincing evidence has been published that corticotropin or cortisone therapy affects antigen-antibody reactions or that it changes positive Coombs' test results to negative ones. Nor is there any rationale for the use of such therapy for sensitized Rh-negative mothers in order to reduce or eliminate the Rh antibody titer. Even assuming that corticotropin (ACTH) or cortisone therapy could stop antibody production, such therapy would be undesirable and impracticable for the following reasons. 1. The injections would have to be given daily throughout the entire nine months of pregnancy. 2. The therapy, if it were effective, would stop all antibody production, not merely Rh antibody production alone. This would leave the mother vulnerable to a fatal sepsis caused by invasion into her blood stream of pathogenic organisms to which she will have lost her immunity. 3. The effects, if any, of the therapy would show themselves very slowly, due to the long half life of 35 days of antibody molecules (Wiener, A. S.: The Half-Life of Passively Acquired Antibody Globulin Molecules in Infants, *J. Exper. Med.* **94**:213-221 [Sept.] 1951). Thus, if the initial antibody titer is 100 units, for example, it would take at least 35 days until the titer dropped to 50 units, and another 35 days for it to drop to 25 units. Considering that the titration method itself has a large technical error of about 100 to 200%, even if the therapy were effective it would take at least two or three months before the titrations could reliably demonstrate any fall in titer. Certainly, injections given only during the latter months of the pregnancy would be useless. Summarizing, therefore, there is no rationale for the use of corticotropin (ACTH) or cortisone for treating Rh sensitization, and such therapy is not recommended.

A DISTURBED CHILD

To the Editor:—*An 8-year-old boy is physically and mentally sound but emotionally unstable. His birth was normal, and his only severe sickness was rubella at age of 15 months, at which time he had one convulsion with a temperature of 105 F. His physical development is good except that he is very fat. A basal metabolism rate cannot be taken owing to his fearfulness. The child wakes at night crying. He craves sweets and vegetables, will not eat meat, and will not fight back when intimidated. Would you advise application of thyroid extract,* d*-amphetamine sulfate (dexedrine®), diet with punishment to make him eat a rounded diet, sedatives at night, or psychiatry?*

M.D., North Carolina.

Answer.—This boy undoubtedly has a complex of fears and frustrations, which causes the symptoms enumerated, night crying, craving for sweets and vegetables, and refusal to eat meat. Thyroid extract, *d*-amphetamine sulfate, and diet and punishment will be unavailing until his fears and frustrations are investigated. Psychiatry or mental hygiene would seem the best solution for this child's problems; if these are not immediately available, sedatives at night might be useful.

MECHANICAL APTITUDE

To the Editor:—*A father is interested in working with mechanical and electrical machines, although his vocation is that of a department store manager. He declares that his son does not know about his interest and ability in practical mechanics but insists that the boy has inherited his mechanical ability. He feels that the interest and ability that his son exhibits is an inherited characteristic. I would appreciate your opinion about this.* *M.D., Pennsylvania.*

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—Possible inheritance of mechanical aptitudes has been little studied, but L. Dewey Anderson found such abilities, in junior high school boys, were largely independent of the economic status of the home or even of such factors as the number of tools owned by the father. General intelligence is found to account for only about one-sixth of a person's mechanical ability, and the very gifted children studied by L. M. Terman in California actually fell below the average of their schools in mechanical ingenuity. This may have been due partly to a lack of interest and to overspecialization along abstract lines. But all of these lines of investigation suggest that the basis of mechanical abilities is in some way inherited and is not dependent merely on training or imitation.

Answer.—There appears to be no significant investigation on the possible inheritance of mechanical ability. An unequivocal answer to the question is therefore impossible at this time. There is, however, no valid reason for doubting the possibility and even the probability of a genetic basis for mechanical competence, although of course environment must also play a part in the development of such competence.

ENTERITIS IN TOURISTS

To the Editor:—*I have read with much interest the views expressed on the subject of enteritis in tourists in* The Journal, *January 12, 1952, page 164. Enteritis in tourists is a well-recognized phenomenon in India, and it probably is due to the same cause there as in countries like Mexico and Egypt. The condition is found in countries in which the climate is tropical or subtropical and the prevailing standards of hygiene are poor.*

We have investigated many cases of this condition, which is due to bacillary dysentery. Examination of fecal specimens early in the illness will reveal the presence of bacillary exudate, which is often profuse. The causative organism is a bacillus of the Flexner type. In this part of India, the condition is found less often in tourists, since we have few tourists, than in newcomers and visitors. Newcomers from Europe are notoriously likely to get bacillary dysentery within a short time after their arrival. It would probably be no exaggeration to say that all get it. Immunity to the local strain is soon acquired. In the case of "permanent" residents, a holiday visit to a hill-station or to a distant part of the country is likely to entail an unwelcome but inevitable introduction to a different strain of the causative bacillus, manifested by another attack of dysentery. These are commonplace facts known to discerning medical men and laymen.

The remedy is not to be sought in avoiding any particular type of food or cooking medium or even in confining one's milieu to international hotels. The disease is an infection highly amenable to prompt treatment by sulfaguanidine. If this is realized, the need for transoceanic telephone calls or rushing from the country in panic never to return need not and indeed will not, arise.

W. B. Roantree, M.D., Kolar Gold Field,
Champion Reefs, Post Office, South India.

TULAREMIA

To the Editor:—*In* The Journal *Nov. 17, 1951 (page 1184), in Queries and Minor Notes is a question about tularemia. I treat about 12 cases of tularemia every year in this community, and I have found that streptomycin, given in a dose of 0.3 gm. every 3 hours for a patient weighing 150 lb. (68 kg.), is very effective. In three to five days all symptoms disappear.*

In a serious disease such as tularemia it would not be advisable to experiment with a dose of ½ or 1 gm. given every 24 hours. In the treatment of children the fraction by weight of the above dose will accomplish the same results, and the same is true of a patient excessive in weight. I treated many patients for tularemia before the advent of streptomycin and, therefore, have been able to compare the effect on the prolongation of the disease of streptomycin therapy and other therapy. Results with the use of streptomycin have been amazingly good. I would suggest that the patient mentioned be given streptomycin, even at this late date.

G. T. Stewart, M.D., Mena, Ark.

ANTIBIOTIC THERAPY OR TONSILLECTOMY

To the Editor:—*In response to the question in Queries and Minor Notes* in The Journal (148:978 [March 15] 1952) *"Can a diseased tonsil be cured by antibiotic therapy without an operation?" I wish to report that I have had several patients in whom antibiotics administered in aerosol form have apparently cured chronically diseased tonsils with secondary lymphadenopathy. The most important factor is selection of the proper antibiotic, which is best done by culture and in vitro inhibition testing. It is also possible that a suitably selected antibiotic administered by other means than the aerosol method may be effective.*

Samuel J. Prigal, M.D.
55 Park Ave., New York 16.

GAS EMBOLISM AND THE RUBIN TEST

To the Editor:—*In reply to the question in* The Journal *April 12, 1952 (page 1364), whether gas (carbon dioxide) embolism has been seen after tubal insufflation, it is stated that there is no record of such an occurrence. May I call attention to my report published in* The Journal (89:522-523), *Aug. 13, 1927, in which two cases of death following insufflation of the fallopian tubes were reported. In one patient, oxygen was used. In the second patient (a 36-year-old white woman), carbon dioxide insufflation was done; the tubes were found to be closed, and dilatation and curettage were then performed. The woman collapsed and died on the operating table. Necropsy, done a few hours after death, showed the tubes to be closed, with blood and gas in the right fallopian tube and numerous gas bubbles in the right side of heart, the inferior vena cava, and the right femoral vein.*

I thought you would like to be informed of this case to keep the record straight. Anent the fatality with carbon dioxide insufflation of the tubes that I reported, Rubin (Fertil. & Steril. **3**:179, 1952), *reported three embolic episodes. Luckily, these were not fatal, but they might have been. My case is, therefore, within the realm of possibility. To assume the occurrence of an air embolus owing to the curettage is a rather specious supposition. How many times after the millions of uterine scrapings that have been done has the occurrence of an air embolus been reported? This does not defend in any way the use of curettage after insufflation. I agree with Rubin that carbon dioxide insufflation is the therapy of choice. I believe the iodized oil method and other methods should be used only to determine the exact site of the tubal obstruction, if the patient desires operative interference.*

27 West 55th St., New York.

SYPHILOPHOBIA

To the Editor:—*In* The Journal, *March 8, 1952, page 877, the answer to a query on syphilophobia states:*

> *"There are some physicians who feel that if such efforts fail, he [the patient] might be given treatment with repository penicillin for early syphilis as a psychotherapeutic measure, provided there is some chance that this treatment will eradicate his phobia. Others suggest that placebo injections of sterile water would be equally effective."*

The treatment of a severe phobia such as described in this case by penicillin or by placebo injections is illogical. There could be no better way of reinforcing and fixing the syphilophobia than by treating the patient for the nonexistent disease that he fears. Confirming his fears by such injections not only would not eradicate his phobia but would make subsequent psychotherapy just about impossible.

This patient is in urgent need of psychiatric help. Syphilophobia in a 30-year-old male after extramarital intercourse points to the presence of severe guilt feelings and emotional conflict. Such a phobia may, in certain instances, be the first symptom of a more malignant condition, such as schizophrenia.

Bernard L. Diamond, M.D.
291 Geary St.
San Francisco 2.

To the Editor:—*This letter concerns a reply to a question about syphilophobia, which appeared in the March 8 issue of* The Journal *under Queries and Minor Notes.*

Certainly the rationale for treating a psychiatric condition with penicillin is about as logical as treating a surgical condition with psychotherapy. I feel sure that most other psychiatrists will agree that the use of penicillin in syphilophobia is not only useless but harmful. Statements suggesting a totally inappropriate therapy for psychiatric conditions appear all too often. Why cannot psychiatric treatment be openly recommended for an obviously emotional condition?

ANESTHESIOLOGY: A CHALLENGE

CHAIRMAN'S ADDRESS

Stevens J. Martin, M.D., Ph.D., Hartford, Conn.

What I have to say is neither scientific, pedagogic, nor semantic, but consists rather of a forthright analysis, in retrospect, of the challenges a physician accepts in the field of anesthesiology. Have we ever stopped to consider our reasons for studying anesthesia and why others should join us? Have we ever wondered why anesthesiology catapulted from an empirical art to an accepted specialty based on sound laboratory and clinical studies in the short span of three decades,[1] why residencies increased in number from 38 to 196 in 10 years,[2] why the American Medical Association, the armed forces, and various institutions accepted anesthesiology as a specialty,[3] why our membership soared from 3,500 to over 3,800 this past year, and why in this postwar era there has been an ever-growing demand for anesthesiologists [4] by the surgeon, patient, and hospital administrator? There must be some cogent reasons for this phenomenal progress and for the entrance into our specialty of interns, general practitioners, and doctors of physiology and pharmacology. What challenges in anesthesiology are being accepted? One should pause to reflect whether any or all have been accepted.

It should be clearly understood that the anesthesiologist is first a physician and only secondly a specialist. His field, in its entirety, was accepted by him as the ideal *modus operandi* through which the Hippocratic Oath can best be fulfilled. Accordingly, his duties, obligations, and responsibilities are carried out resolutely and cheerfully, for he is certain that it is his optimal approach in providing comfort and care to the sick and wounded. There is no place in anesthesia for those who are not prepared to accept this fundamental challenge. "The great use of life is to spend it for something that outlasts it."[5] No doctrine of ethical conduct that overlooks this wider destiny for person and community has anything but a stopgap value.

The history of anesthesiology dates back to time immemorial [1]; however, a survey of its progress during the past century reveals a series of doubts, claims, accusations, and defiances that have run the gamut from a single clinical trial to a congressional controversy, from a wave of enthusiasm for a new anesthetic agent to a wave of condemnation, until it has been stabilized and accepted as a result of sound experimental and clinical evaluation. Such a mixture of doubt and certainty is not accidental. It is the essence of scientific method; moreover, it is not a characteristic peculiar to science. Anesthesiology was destined, therefore, to flourish but not without its trials. The decisions in some of these challenging problems must be left to posterity—for others to make.

PROFESSIONAL CHALLENGE

The first challenge is the obvious and important professional one engendered of necessity by the rapid strides in the field of surgery. Anesthesiology and surgery are inseparable fields, interdependent and having mutual interest. The anesthetic requirements of surgery, we well know, have changed from the transient analgesia and unconsciousness of the old days to the elaborate, highly technical needs of today. Our challenge is to provide what may now be termed modern anesthesia. It may be defined as a reversible depression of the central nervous system (general anesthesia) with loss of pain and consciousness, graded skeletal muscular relaxation, control of adverse autonomic reflexes, and minimal interference with heat and fluid balance and with the activity of the other vital systems of the body. Such a challenge has extended modern anesthetic management to include preanesthetic and postanesthetic care and the supervision of fluid and inhalation therapy.[6] It demands not only finesse in technique but, more important, a constant

alertness to the principles of physiology and pharmacology to avoid aberrations during anesthesia. Today, no one denies that surgical and anesthetic morbidity and mortality have been significantly decreased by the present methods of anesthetic management.

The professional challenge to anesthesiology has come also from quarters other than surgery. The problems of obstetric analgesia and anesthesia and of infant resuscitation have confronted us for many years.[7] Recently, these problems, like those of pediatric anesthesia,[8] have been studied with such zeal that specialties within our specialty have developed. Some difficulties of internists have been shared also by us. Medical literature is replete with reports of diagnostic and therapeutic regional anesthetic techniques and of the treatment of gas and drug poisoning of the nonsurgical patient.[9] The general practitioner has also presented a challenge to anesthesiology in his search for analgesic substitutes and methods for treatment of asphyxia and the control of convulsions. In a sense, therefore, the professional challenge to anesthesia is inescapable and permanent.

Anesthesia is now an established specialty, and its continued progress is assured. The pertinent question is "How have we met its professional challenge?" Have we eased the surgeon's burden and contributed to his success? Have we made our services indispensable to the hospital's staffs? Have we developed the *esprit de corps* with our surgical and medical confreres that results in mutual respect, admiration, and esteem? In the course of our patient-relationship, have we succeeded in obtaining the patient's confidence, cooperation, and good will? Do we possess adequate knowledge of the basic medical sciences, proficiency in our techniques, and mature judgment in our anesthetic management? Our continued progress proves that the vast majority of anesthesiologists have successfully met the professional challenge.

EDUCATIONAL CHALLENGE

Of importance, also, is the educational challenge to anesthesiology. Our pioneers both here and abroad were self-taught and self-desciplined, advancing only through the uncertainties, setbacks, and rewards of trial and error, with limited means of public expression and professional communication. There was an occasional preceptor whose clinical (and perhaps laboratory) experiences were mature, organized, and enthusiastically presented to apprentices. We should praise such men and their works, but a still more important duty is to improve on what they have done. Our educational challenge was finally crystallized by the inauguration of the residency or fellowship program of instruction in anesthesiology in 1927. As our appreciation and correlation of basic medical sciences developed and our application and perfection of newer anesthetic agents and techniques improved, instruction became more fruitful and served as a great stimulus to our progress. The American Board of Anesthesiology was founded in 1937, our Section on Anesthesiology was authorized by the American Medical Association in 1940,[3a] and in the same year the specialty was recognized by the Army.[3b] Recognition by civilian hospitals and universities promptly followed. Necessities of World War II and its civilian aftermath created an even greater demand for instruction in anesthesiology. Today, enthusiasm for teaching others is predominant, while the urge to learn flourishes.

A variety of instruction programs in anesthesiology are available and vary from that qualifying a physician for certification by the American Board of Anesthesiology to one day sessions for those interested in anesthesiology on a part-time basis. There are now 196 approved residencies for some 600 candidates, a few preceptorships, and over 110 instruction centers for the general practitioner for one day to six month courses. In addition, there are annual refresher course programs sponsored by the Committee on Medical Schools and Postgraduate Education of the American Society of Anesthesiologists and countless numbers of regional, state, county, municipal, and local hospital meetings on anesthesiology. The challenge to our educational needs has been met also by innumerable laboratory investigations by both fellow anesthetists and workers in the fields of physiology, pharmacology, and chemistry. Such studies have been mutually stimulating and productive. They have proved to be indispensable in the scientific development of anesthesia.[10]

The educational challenge to anesthesiology, while slow in onset and only recently met with vigor, is a natural one. Our status as a specialty is relatively new and our progress gratifyingly rapid. Have we been immature, naïve, and overly impulsive in meeting our educational challenge, or have we not met it adequately? Without question, it appears that we have fallen short of our goal. Our national and state placement committees as well as many centers of instruction have been virtually deluged with requests for anesthesiologists. Although our society membership is increasing annually, the disparity between the number of demands and the number of available competent anesthesiologists continues to increase. Urgent requests have come not only from surgeons and hospital superintendents but, significantly, from lay members of hospital boards of trustees as well. This situation is acute, and our educational challenge now is formidable; however, our over-all teaching effort and facilities can absorb three times the number of trainees. What, then, is our problem? Bluntly speaking, it is our inability, by precept or example, to entice enough future anesthesiologists. Our failure, in a great measure, is due to inadequate or improper indoctrination of medical school students and interns in the principles and practice of anesthesia. Our educational effort could be most productive at this grass roots level, and it must be strengthened.[11] One wonders if the responsibility for meeting this challenge could not be shared with the American Board of Surgery, the deans of medical schools, and the directors of house staff instruction.

ECONOMIC AND ETHICAL CHALLENGES

Economics and ethics in the practice of anesthesia constitute two more significant present-day challenges. Their thorough appreciation and application is imperative if anesthesiology is to survive the insidious growth of the institutional practice of medicine, if we are to retain free enterprise in medicine, and if we are to continue to provide the modern anesthetic management our patients need and our surgeons demand. The administration of anesthetic agents is the practice of medicine, and, when it is regarded as such, the relationship of the anesthesiologist to his patient becomes clear-cut and inviolate. His conduct and responsibilities are similar to those in any other patient-physician relationship. The American Medical Association's "Guides for Conduct of Physicians in Relationships with Institutions,"[12] approved last December, and the American Society of Anesthesiologists' "Statement of Policy"[13] have been invaluable statements of our challenge and course of action in the best interest of our patients. Admittedly, these reports have served as a great impetus to our progress.

The Committee on Economics of the American Society of Anesthesiologists, in an extensive study in 1949,[14] revealed that 75% of the anesthesiologists in this country were engaged in private anesthesia on a fee-for-service basis. Of even greater importance is the 1951 report of the Armed Forces Committee of our society,[15] which showed that close to 80% of anesthesiologists are engaged in the private practice of anesthesia. This is very significant, for with such an economic future and accepted ethical standard, more will enter our profession; however, there is still much to be accomplished to meet our economic challenge. If the stand of the American Medical Association and the American Society of Anesthesiologists is correct and if the national trend is in favor of the policy of private fee-for-service anesthesia, then is it irreconcilable that 20% of our members do not conform? Is their interpretation of the national policy on economics and ethics in the practice of anesthesia based on local, regional, or other factors not yet clarified or known? Or, is it the dogmatic and persistent opposition of the American Hospital Association that makes conformity difficult?

SOCIOLOGIC CHALLENGE

Another challenge to anesthesia, one of increasing significance at long last, is the sociologic challenge. This is to be expected, for anesthesia, like other specialties, cannot divorce itself from the role played by medicine in contributing to America's leadership in world health and achievement. While the anesthesiologist is first a physician and secondly a specialist, he must not forget that he is also a citizen and a member of a community. Accordingly, he welcomes his community responsibilities.[16] His participation in various charity drives and his membership in athletic, political, and, religious groups provides him the opportunity to show understanding and leadership as a representative of the medical profession. With the individualization of anesthetic management for optimum safety and success, the close patient-physician relationship, the support by surgical colleagues, and the favorable commentaries on anesthesiology in lay journals, the public has become less mystified, less fearful, and less reluctant to accept anesthesia. In fact, some patients have gone further and not only inquire about the anesthesia they are to receive but demand the services of an anesthesiologist. History repeats itself, for it was only about two decades ago that parturient women began to prefer the services of the obstetrician and the general practitioner trained in obstetrics to those of the midwife or other technician.[17]

Anesthesia is an indispensable adjunct to the modern practice of medicine. As we meet our sociologic challenge successfully, the public will join our medical colleagues in contributing to our progress and stimulating us to greater effort. With increasing public demand and the already established need for modern anesthesia by our medical colleagues, it is not too early to predict the fulfillment of the recommendations of the American College of Surgeons, concurred in by the American Medical Association, that[4] there be at least one competent anesthesiologist serving each hospital in which anesthetics are administered. It is also not too unrealistic to say that such a recommendation not only will improve public relations but will also make our professional, educational, and economic challenges in anesthesiology less arduous to meet and more willingly accepted.

SUMMARY

Anesthesiology as a more recently accepted specialty in medicine, is faced with many challenges. The professional, educational, economic, and sociologic challenges are of paramount importance at the present time. Considerable success has been achieved in meeting the professional challenge; however, there is much to be accomplished in meeting the educational, economic, and sociologic challenges, if anesthesia is to maintain its rightful respected place in medicine. Our efforts must be strengthened, and with the support of our medical colleagues and an enlightened and aroused public, we cannot help but succeed in meeting all our challenges. Let us do all in our power to follow a precept of Lucretius that "Men live in a mutual dependence and, like runners, transmit the torch of life."[18]

ACUTE POISONING WITH SODIUM FLUOROACETATE (COMPOUND 1080)

Joseph W. E. Harrisson, D.Sc., Julian L. Ambrus, M.D., Clara M. Ambrus, M.D.
Edward W. Rees, B.Sc., Philadelphia, Robert H. Peters Jr., M.D., Lewis C. Reese, M.D.
and
Theodore Baker, M.D., Kingston, Pa.

Since the report of Kalmbach [1] on the rodenticide activity of fluoroacetate (compound 1080) this compound has been extensively used by government agencies, the armed forces, and privately employed exterminators. In spite of its high toxicity to all species, relatively few cases of human poisonings have been reported so far, none of which have ended fatally.[2] All of the victims took small, but unidentified, quantities of fluoroacetate. The toxic dose for human beings has not been established, but on the basis of animal studies it has been theorized as being approximately 5 mg. per kilogram of body weight. The case reported here ended fatally, pathological examination was performed, and the quantities of fluoroacetate in the organs were determined. For the experimental literature on fluoroacetate we may refer the reader to the recent reviews by Chenoweth [3] and by us.[4]

REPORT OF CASE

A white man, about 40 years of age, was found on Feb. 3, 1949, noon, in his bedroom at home in an unconscious state. He was admitted to the emergency ward with the information from his wife that he had probably taken sodium fluoroacetate.

Past History.—According to his wife, who had known him since birth, he never had any serious illness or operation until after being discharged from the Army after World War II. At this time he was hospitalized with battle fatigue for six months. He received shock treatment for "severe depression." He was discharged December, 1940, and readmitted from October to December, 1947. The diagnosis was manic depressive psychosis. His family was warned of danger of possible suicide. The family history was essentially negative.

Examination on Admission.—He was unconscious and had nystagmus of both eyes and slight muscular spasms. The heart rate was 92, rhythm was irregular, and no murmurs were heard. The abdomen was soft, and between muscle spasms peristalsis was heard.

Therapy and Course.—The stomach was lavaged and magnesium sulfate instilled. He was given a soft soap enema. Following this, nystagmus became pronounced and he had an epileptiform convulsion. For sedation, 2 grains (0.12 gm.) of phenobarbital (luminal®) sodium was given four times and 1/50 grain (1.2 mg.) of scopolamine hydrobromide. Blood pressure had fallen to 90/40 mm. Hg. Plasma was administered and three intracardial injections of 5 ml. of 1% procaine hydrochloride given. Oxygen was administered. Blood pressure rose to 120/180. Muscle spasms continued, perspiration became profuse, the face flushed, he frequently retched and occasionally opened his eyes, and frothing at the mouth occurred. At midnight blood pressure rose to 118/75, pulse 100, respiration 28, and temperature in the axilla 97; he was very restless. Because of excess mucus secretion 1/150 grain (0.4 mg.) of atropine sulfate was given and calcium gluconate was given intramuscularly. At 3 a. m. respiration was labored, and at 5 a. m. the patient was pulseless, ceased breathing, and was pronounced dead.

Pathological Examination.—The skin had a yellowish tint; the scleras were not markedly tinted. There was a small amount of tenacious mucus in the oral cavity. About 100 cc. of clear yellow fluid was found in the left pleural cavity. Numerous epicardial petechiae were mainly about the base of the heart and along the course of the coronary vessels. Two needle punctures were in the right ventricle near the septum. The myocardium was of average normal color and thickness. On standing the color changed to a coppery red color and it had a slightly mottled appearance as though there was interfascicular hemorrhage present. The endocardium and the valves showed no abnormalities. Coronary arteries were free of sclerosis and blood clot. No significant sclerosis was found in the aorta or arterial trunks, and the blood tended to remain fluid. Much diffuse dark red color was seen in the lungs. There were a few small petechiae on the diaphragmatic surface. The cut surfaces were dark red, and on pressure very little air or thick, sanguinous fluid could be expressed. There was intense congestion of the bronchial mucosa. A small amount of sanguinous mucus was in the bronchi.

Tan discoloration of the lower third of the esophageal mucosa was present, and many hemorrhagic partly confluent erosions were on the cardiac portion of the stomach. Toward the pylorus only the crests of the rugae were involved; there was no definite ulceration. The stomach contained about 100 cc. of dark brown fluid. Intense hemorrhagic erosions appeared on the crests of the duodenal mucosa. These became less numerous as the jejunum was approached and were not seen more than a foot beyond the ligament of Treitz.

On the cut surface of the kidneys a slight congestion of the arcuate vessels was observed. The bladder was distended with about 600 cc. of clear yellow urine. Many discrete and confluent petechiae were seen in the mucosa. The cut surface of the liver was more yellowish than usual. There was an irregular prominence of the sinuses suggesting irregular distribution of blood or extravasation. The gallbladder, spleen, and adrenals showed no pathological change on macroscopic examination.

There was a considerable quantity of subarachnoidal fluid of normal appearance present. The arachnoid was studded with whitish granules of 1 to 2 mm. in diameter, which resembled pacchionian granulations but were more widespread. On the floor of the fourth ventricle, immediately subjacent to the ependyma, there were several small petechia-like lesions.

From the Nesbit Memorial Hospital, Kingston, Pa. (Drs. Reese, Peters, and Baker), La Wall and Harrisson Research Laboratories, Philadelphia (Dr. Harrisson and Mr. Rees), and the Department of Pharmacology and Biochemistry of the Philadelphia College of Pharmacy and Science, Philadelphia (Drs. Harrisson, J. L. Ambrus, and C. M. Ambrus).

[4] Harrisson, J. W. E.; Ambrus, J. L., and Ambrus, C. M.: Fluoroacetate (1080) Poisoning, to be published.

Microscopic Examination.—Ecchymoses was present in the epicardial fat, with diffuse venous congestion. Heart muscle seemed to be normal. There was a minimal degree of anthracosis in the lungs. Diffuse vasocongestion and scattered foci of alveoli showed endothelial proliferation suggesting passive congestion. In the bronchi there was marked hemorrhagic edema of the submucosa. There were foci of lymphocytes in the deeper tissues suggesting that there had been a chronic peribronchitis of a mild degree, probably existing for some time. There were a peribronchial node, slight anthracosis, and nodules of caseous tuberculous material with definite peripheral activity (lymphocytes, endothelial cells, and giant cells).

Atropic gastric mucosa was found in the stomach. Numerous erosions, without ulceration, were characterized as small submucosal petechial ecchymoses. There was diffuse tubular degeneration in the kidneys, affecting mainly the convoluted tubules and to a minor extent the collecting tubules and the loops of Henle. The convoluted tubules contained protein exudate. There was general vasodilation. The interstitial tissue was compressed so that it was hardly visible. The glomeruli seemed normal. There was slight, diffuse edema of the sinuses of the liver with some evidence of biliary stasis in the perilobular portions of the lobules and marked passive congestion of the splenic pulp.

In the adrenals there was marked lipoid vacuolization of the fascicular zone and partially of the reticular zone with occasional evidence of pyknosis. The medulla showed considerable evidence of antemortem degenerative changes. The pancreas was essentially normal. Occasional islets were seen in which there were cells with dense eosinophilic cytoplasm.

Adjacent to the substantia nigra there was diffuse vasodilatation with small to moderate sized extravascular hemorrhages. There were numerous small petecchial hemorrhages scattered through the corpora quadrigemina. There was evidence of bleeding both of fresh blood as well as blood that was present long enough to be split to hemosiderin in the phagocytic cells in the perivascular spaces.

TABLE 1.—*Calculated Quantity of Sodium Fluoroacetate in Organs of Patient*

Organ or Contents of Organ	Total Weight of Organ or Quantity of Material	Weight of Sample Tested	Fluorine, Mg. per Kilogram of Organ Weight	Fluorine Calculated to Sodium Fluoroacetate, Mg. per Kilogram of Organ Weight	Calculated Total Sodium Fluoroacetate in Organ, Mg.
Urine, from bladder	600 cc.	300 cc.	70.0	368.0	220
Liver................	1,726 gm.	210 gm.	11.1	58.4	100
Brain	1,450 gm.	237.5 gm.	14.4	75.7	109
Stomach content...	105 gm.	105 gm.	22.5	118.0	12.4
Kidney........ Right: Left:	170 gm. 170 gm.	117 gm.	12.3	64.7	11

Wchnschr. 15:1425, 1936; Fluor und Fluorverbindungen, in Heffter, A.; Heubner, W., and Schüller, J., editors: Handbuch der experimentellen Pharmakologie, Berlin, Julius Springer, 1938, vol. 7, p. 1.

Toxicological Examination.—Fluorine content of the organs and body fluid was determined according to the distillation method of Willard-Winter[5] using a thorium nitrate back titration, following preliminary ashing with an excess of calcium hydroxide to fix the fluorine. From these data the theoretical sodium fluoroacetate content was calculated. The results are shown in table 1. In table 2 the fluorine content of normal human organs is set forth on the basis of the literature.

COMMENT

A fatally ending case of fluoroacetate poisoning is presented. The clinical course suggests that in human beings the central nervous system as well as the cardiac effect of fluoroacetate are manifested. It is known from the experimental literature[6] that some species, such as rabbits, goats, horses, and spider monkeys, exhibit only cardiac symptoms; others, such as dogs, guinea pigs, and frogs, have only convulsions; and again others, including cats, pigs, chicks, and rhesus monkeys, show cardiac as well as central nervous system effects.

The pathological observations are essentially similar to those found by Foss[7] in acute intoxication with fluoroacetate of experimental animals. Human cases and animal intoxications with sodium fluoride exhibit pathological changes[8] indistinguishable from those seen when fluoroacetate is used. Since, however, sodium fluoroacetate is much more toxic than sodium fluoride, it seems likely that the above changes were caused mainly by fluorine, while the special biochemical actions of fluoroacetate produced no pathological changes of diagnostic significance. The death from fluoroacetate poisoning[6] seems to be due to the failure of the heart, exhaustion because of cramps of central origin, and probably toxic depression of the respiratory and vasomotor centers.

It is interesting that in the Langerhans' islands dense eosinophilic cytoplasm was seen. Although it is difficult to draw conclusions on the basis of one case, the observation may indicate a preservative action of fluoroacetate on the enzymic granules.

The distribution of fluoroacetate was relatively uniform in the organs tested. The high level in the urine indicates a rapid urinary excretion. This is in agreement with the findings of Ramsey and Clifford,[9] who found in poisoned rats an even distribution of fluoroacetate between brain, heart, liver, and kidneys. It is significant that in spite of the gastric lavage and the fact that death ensued about 17 hours after the ingestion of the poison, important quantities of the poison were found in the stomach. Brandl and Tappeiner[10] and Gadaskina and Shtessel[11] presented data on the excretion of fluoride through the gastrointestinal tract, and Charnot[12] described fluoride excretion in the bile. Thus it is possible that gastroenterohematic circulation of fluorine compounds exists. Because of these data and the high toxicity of fluoroacetate repeated gastric lavages seem to be advisable.

[9] Ramsey, L. L., and Clifford, P. A.: Determination of Monofluoroacetic Acid in Foods and Biological Materials, J. A. Offic. Agr. Chemists 32:788-797, 1949.

The total quantity of fluoroacetate recovered from the organs and body fluids tested was 465 mg. Since the patient weighed approximately 140 lb. (63.5 kg.), disregarding the fluoroacetate present in organs from which no sample was available for toxicological study, he ingested a minimum of 6 mg. per kilogram of fluoroacetate.

The therapy used in this case was essentially symptomatic: barbiturates to decrease convulsions, intracardial procaine hydrochloride to inhibit ventricular fibrillation, atropine sulfate to decrease bronchial mucus secretion, and plasma transfusion and oxygen to offset vasomotor and respiratory failure. Experimental studies have suggested the use of certain specific antidotes.[6] Of these monacetin was directed for the treatment of this case; however, it arrived too late to be employed.

SUMMARY

1. A case history of fluoroacetate poisoning has been described together with postmortem examination and chemical analysis of the fluoroacetate content of organs and body fluids.

2. It appears that there is no important difference between postmortem findings of sodium fluoroacetate and sodium fluoride poisoning. The additional biochemical effects of sodium fluoroacetate thus seem to have no pathological manifestation of diagnostic significance.

3. Because of indications of gastrointestinal excretion and reabsorption of fluorine compounds, repeated gastric lavages seem to be advisable.

4. Other therapeutic aspects are briefly discussed.

ELECTROENCEPHALOGRAPHIC CHANGES IN PROFESSIONAL BOXERS

Ewald W. Busse, M.D.

and

Albert J. Silverman, M.D., Denver

Since the days of the Roman gladiators, men have fought each other and other persons have watched. The sport of boxing, as it exists today, is largely the product of psychological forces that have not changed in essence for 2,000 years. It is the feeling of many persons that in spite of periodic criticism and the efforts to ban prize fighting, the sport will persist. Since it appears unlikely that athletic contests requiring physical contact will ever cease, the physician should attempt to safeguard the physical and mental health of the participants.

Much has been accomplished to protect the athlete in such sports as football and ice hockey, but protective measures for the amateur and professional pugilist have not kept pace. Jokl[1] in his monograph (1941), which is concerned with the medical aspects of boxing, recognized and deplored this situation, and he collected a wide variety of case material that was representative of possible sequelae due to boxing injuries. Raevuori-Nallinmaa[2] in a recent publication states his belief that the usual cause of death related to boxing is intracranial hemorrhage. Tragic and sobering though they be, deaths of this kind are relatively rare. More important, and certainly much commoner, are the mild psychic changes observed in a high percentage of boxers. These changes are due to brain damage, which is also responsible for the less frequently seen, so-called "punch-drunk" person, who is in fact in a state of traumatic dementia and reveals severe psychic and neurological abnormalities.

The syndrome of boxing encephalopathy is probably due to multiple concussion hemorrhages as well as to contusion and laceration of the brain. The "knockouts" and "technical or near knockouts" (representing states of commotio cerebri) are usually the result of a trauma that alters brain function. If the trauma is severe or is mild but repeated at intervals that do not permit the brain to return to normal functioning, permanent damage may result.

Many investigators have reported on the value of the electroencephalogram in the detection of brain injuries. Dow, Ulett, and Raff,[3] in doing electroencephalograms of persons immediately after injury, reported that a

mild cerebral trauma produced electroencephalographic changes that decreased in abnormality within a few minutes. If amnesia was associated with the trauma, but the patient was clear-minded when his record was taken, there was only a slight increase in the percentage of abnormal records. If consciousness was at all impaired at the time of the electroencephalogram, there were invariable, accompanying electroencephalographic changes. Abnormal findings recorded immediately after head trauma may become normal, however, for Dow and associates found that a larger number of records were abnormal when taken less than a half hour after injury. This points to some mechanism in concussion other than such factors as petechia, contusion, and emboli, each of which would take several days to disappear. Williams [4] found invariable electroencephalographic changes accompanying altered consciousness as a result of head injury and stated that concussion is the result of widespread disorganization of cerebral function. Strauss [5] found diffuse slowing in patients with clouded consciousness but noted a more selective slowing in frontal areas of patients showing facetiousness. Ward and Clark [6] indicated that concussion or localized blows to the cortex resulted in changes in the electroencephalogram identical to those produced by rapid rises in intracranial pressure. Jokl [1] supported this by his contention that at the *moment of* the blow to the head there was a sharp rise of intracranial pressure.

In their experimental studies Zimmerman and Putnam [7] reported that minimum cell changes could occur without electroencephalographic changes but found that when the trauma was severe enough to cause "incompletely reversible cell changes" there was a direct relationship between severity of cell changes and severity of electroencephalographic abnormalities. They also reported a reduction in voltages that was directly proportional to the amount of force applied. Heppanstall and Hill [8] stated that focal findings were generally significant of symptomatic rather than idiopathic disorders and that there was a greater chance of permanent electroencephalographic changes in persons who sustained head injuries when they were under the age of 20. Kaufman and Walker [9] reported that in about two-thirds of their patients convlusive disorders developed after acute and severe head injuries. Abnormal electroencephalograms were seen in 90% of those patients in whom seizures developed and in more than 75% of those without seizures. Focal abnormalities were noted in over 80% of the epileptics and in over 65% of the nonepileptics. Greenblatt,[10] reporting on post-traumatic patients with convulsions, fainting spells, psychoses, or other personality disorders, found that 68% had disturbed electroencephalograms. Regarding minor head injuries, Harris and co-workers [11] stated that abnormal waves may be found in hyperventilation only and that a good prognosis can be made from serial electroencephalograms in which the tracings become more normal. Other investigators, in discussing electroencephalographic changes following head injury, reported different findings. Amplitude asymmetries [12] and bursts of six to eight per second activity [13] were noted by some, while others [14] reported decreases in voltage and increases or decreases in frequency.

Thus, it is evident that the electroencephalogram has no specific pattern in head injury and that any abnormality may be seen, depending on whether there is a temporary physiological disturbance or actual organic damage. The site of injury also has some bearing on electroencephalographic findings.

METHOD AND PROCEDURE

In order to help prevent serious injuries or death, the state athletic commission of Colorado, acting on the recommendation of one of the authors of this article (E. W. B.), unanimously passed a regulation requiring periodic electroencephalographic examinations on all professional boxers performing in Colorado. Although several states recommend the examination in specific cases, the authors do not know of any other state in which such electroencephalograms are compulsory. The regulations as set up by the state athletic commission were as follows: 1. A professional boxer must have an electroencephalogram at least once a year. 2. In the case of a "knockout," an electroencephalogram must be done within two weeks of the injury. 3. Frequent, repeated examinations could be done in the case of a boxer with suspicious recording.

Our purpose in this article is to record the results obtained from the first year's electroencephalograms as an initial report and to attempt to evaluate the worth of the electroencephalogram in safeguarding the health of those who participate in boxing. A Grass eight-channel electroencephalograph was used. So-called active lead placements were left and right frontals, motors, occipitals, and anterior and posterior temporals. Reference electrodes included the ears and vertex leads. Additional leads were used in specific cases as indicated. Records were classified according to the method described by Gibbs, Gibbs, and Lennox.[15] Activation with hyperventilation was performed routinely. Monopolar and bipolar tracings were done in each case, and a natural sleep record was obtained whenever possible.

RESULTS

Thirty electroencephalograms as outlined above were done on 24 boxers. Their age distribution (divided arbitrarily into four groups) was as follows:

No. of Men	Age Group, Yr.
3	18-20
12	21-23
5	24-26
4	27-29

Of the electroencephalograms done on these men, 4 showed severe disturbance, 5 were moderately dysrhythmic, and 15 were within normal limits; thus, the total number of records showing disturbance amounted to 37.5% of the series. This is well above the 10 to 15% reported by Gibbs, Gibbs, and Lennox [15] and others in control groups, whose findings are in accord with those in our own control series.[16] *These figures have statistical significance in that there are only three chances in a hundred that they are due to coincidence.*

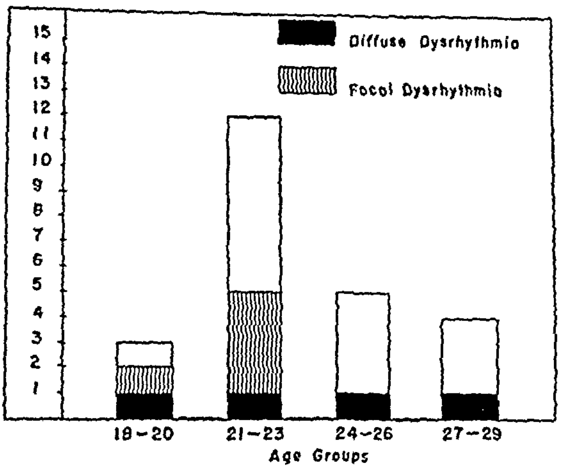

Fig. 1.—Incidence of abnormal electroencephalograms in boxers by age groups.

Type of Abnormality Seen.—There were four records showing severe disturbance. Three of these showed a temporal slow-wave focus, and one revealed diffuse slowing and paroxysms. Five records showing moderate disturbance were noted. Three of these were diffusely slow, and two were indicative of temporal slow-wave foci. Thus, in totaling the severely and moderately disturbed records, five were found to be focal and four showed diffuse findings. (In addition, paroxysms were seen in one each of the focal and diffuse records.) One record showing diffuse disturbance was found in each of the four age groups, while all the focal disturbances were present in the two youngest age groups. It was also noted that, although abnormalities were found in each age group, records showing disturbance seemed to be more frequent in the youngest men; but because of the few cases involved, this could not be statistically corroborated (fig. 1). In order to evaluate the report of decreased voltages in post-traumatic cases,[14] our records were also reviewed with this in mind, and six were found in which voltages were generally decreased. This was not significantly more than the 20% of low-voltage records expected in normal persons.

When we attempted to correlate history of knockouts with electroencephalogram disturbance, the following facts were noted: Ten of the 24 fighters had been knocked out in their ring careers at least once. Four of the 10 had dysrhythmic records, three being severely abnormal and one only moderately so. In the remaining 14 fighters, none of whom had ever been knocked out, one record showing severe disturbance and four showing moderate abnormalities were found. Because the number of records under study was not large enough, these findings are not statistically significant. It is noteworthy, however, that although there was an equal number of records showing disturbance in both groups, the men who had been rendered unconscious had electroencephalograms showing the severer disturbances. These findings were consistent with those of other investigators previously mentioned (fig. 2).

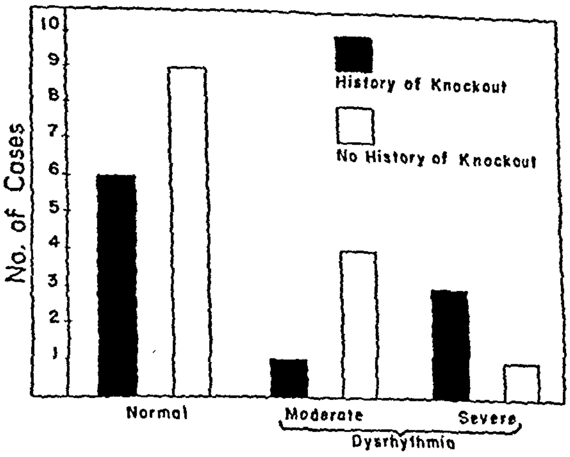

Fig. 2.—Comparative electroencephalographic findings of boxers with and without a history of knockout.

An attempt was also made to determine if length of ring career could be correlated with electroencephalographic disturbances, but no correlation was found. Electroencephalograms showing severe disturbances were seen in boxers who had been in from 2 to 50 fights, moderate dysrhythmias in men who had had from 1 to 15 fights, and normal records in men who had participated in from 1 to 106 fights. This lack of correlation is commented on below.

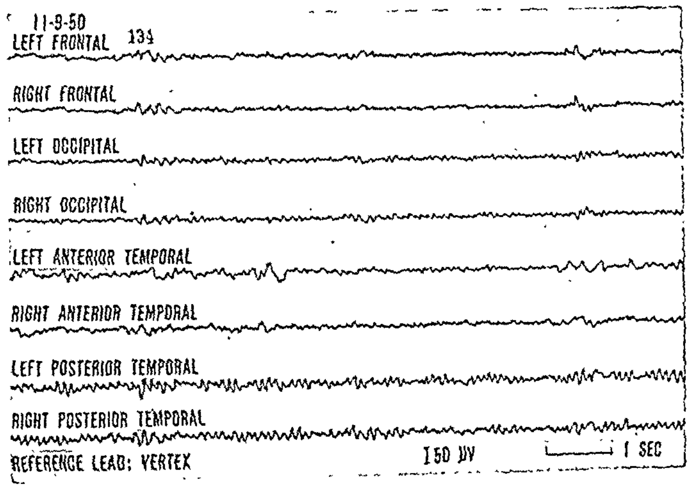

Fig. 3.—Initial electroencephalogram of professional boxer in case reported. Note the slow-wave focus in the left anterior temporal area.

---

[16] In our control series of 329 patients, whose ages ranged from 18 to 54 years, it was noted that 36 (10.94%) showed moderate disturbances and 10 (3.04%) severe dysrhythmias, so that the total of records showing disturbance was 13.98%.

REPORT OF A CASE

The patient, a professional boxer, aged 21, was first seen by us in November, 1950. He had had three professional fights prior to his first electroencephalogram. In July, 1950, he was knocked out, but the following month he won his next fight by a technical knockout in the first round. Three days before a scheduled fight in November, 1950, the patient had his first electroencephalogram, which revealed a left temporal slow-wave focus. The fight was cancelled. A repeat electroencephalogram revealed more extensive temporal focal findings. (The patient, incidentally, showed no abnormal neurological or psychological signs or symptoms at any time.) He was temporarily suspended from boxing, but continued to train. A third electroencephalogram in January, 1951, revealed the persistence of the focus and the addition of paroxysms. This suggested that he had received additional brain injury during the period of training, from which he could not legally be prohibited. It was now believed that this man had suffered some degree of irreversible damage, and he was permanently suspended from boxing on Jan. 16, 1951, for his own good. It was felt that in this case the electroencephalogram had picked up intracranial damage before it had become clinically apparent and that late neurological disability or even death had possibly been averted by this decision (fig. 3, 4, and 5).

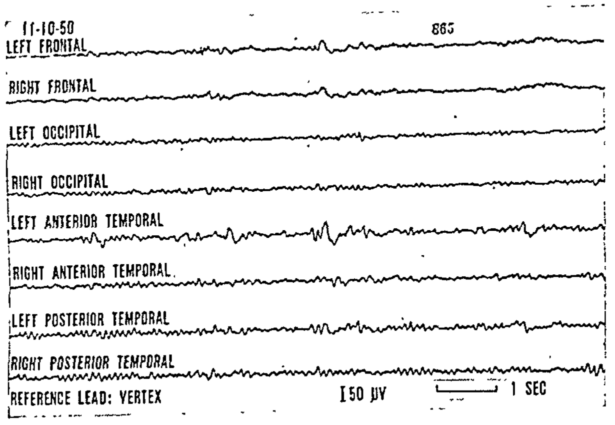

Fig. 4.—Repeat electroencephalographic examination of boxer in case reported. By comparison with figure 3, the focal disturbance now appears to consist of higher amplitude and slower waves.

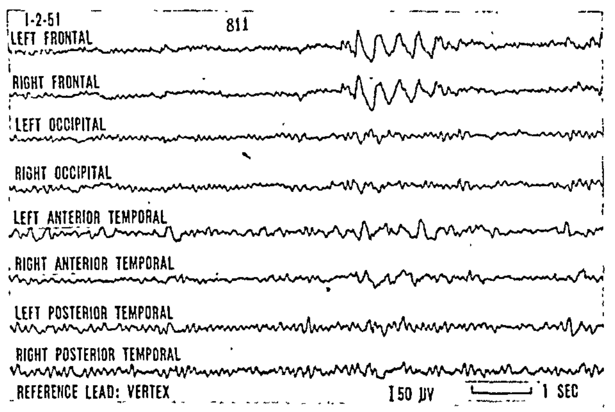

Fig. 5.—Final electroencephalographic examination of boxer in case reported. Note the persistence of the left anterior temporal slow-wave focus and its occasional reflection in the right temporal area. Note also the brief paroxysm of slow waves occurring in the frontal area.

COMMENT

Even in this small group of professional boxers used as a pilot study, it was at once apparent that their series of electroencephalograms were more frequently abnormal than those seen in control studies. It was noted that as many disturbed records were seen in the group who had not been knocked out as in their more unfortunate colleagues. In spite of this there was some indication that those who had definitely been knocked out showed severer disturbances. It should be pointed out that very little background material was actually available to us; for example, the number of times a man had been hit severely enough to cause him to be dazed without actual loss of consciousness, the number of amateur fights, and the extent and severity of training were not known. Thus, because of lack of such information, the correlation between number of professional fights and the electroencephalogram reading had no apparent meaning.

Concerning the abnormalities seen, diffuse records were found in every age group, while focal records were confined to the younger men. Thus, abnormal findings appeared more frequently in the younger age groups because of this very preponderance of focal records in them. These findings support the well-known fact that focal disturbances are good evidence of actual brain damage. There were relatively fewer records showing disturbance in the older men in our study. One can speculate that these men, for the most part, had been fighting for years and, having escaped brain damage in their first fights, were more experienced and better able to avoid injury in the ring. In addition, attention should be directed to the established fact that there are individual differences regarding susceptibility to trauma, so that in any group of boxers exposed to injury over a period of time it is likely that the more susceptible men are soon damaged permanently and retire from the ring, leaving their less susceptible fellows to carry on. An interesting clinical observation made during this study was that the men who showed focal temporal electroencephalographic abnormalities appeared to be, generally speaking, much more aggressive while fighting; and it is our feeling that this aggressiveness, together with the hint of impaired judgment as noted, may be associated in some way with the temporal lobe foci seen in these men. We feel that case material provided by boxers will provide much information about minor repeated head injuries, and future, better controlled, more extensive studies on larger groups may bring much interesting knowledge to light.

SUMMARY AND CONCLUSION

Compulsory electroencephalographic examinations were made on 24 professional boxers with the cooperation of the state athletic commission of Colorado. A statistically significant, increased incidence of dysrhythmic electroencephalograms was found in nine boxers (37.5%) in our series. There was some indication that men who had been knocked out showed severer electroencephalographic disturbances than those who had not been knocked out. Focal disturbances were more frequent in the younger men than in the older men, who also, generally speaking, had fewer electroencephalographic disturbances. A case of a boxer is presented who was finally suspended from boxing largely on the basis of progressive encephalographic abnormalities. From the above findings it is concluded that periodic, compulsory electroencephalographic examinations contribute to the protection of boxers and should be a required part of routine examinations.

DETECTION OF OCCULT BLOOD AS A ROUTINE OFFICE PROCEDURE

Elwood W. Mason, M.D.
and
Frank H. Belfus, M.D., Milwaukee

Death from malignant diseases now holds the second position as a destroyer of human life in America. Most physicians have had the disquieting experience of making the diagnosis of malignant disease too late to be able to offer any effective treatment. Our great hope for the future lies in the discovery of some agent that will destroy malignant tissue wherever it exists or perhaps will even prevent the very inception of malignant disease. Until the day when such an agent becomes a practical actuality, we must content ourselves with the use of the tools at hand.

A nation-wide campaign is under way to educate the public in the early detection of cancer. It therefore behooves us as physicians to reexamine and to use every practical means available to detect the presence of cancer in its early phases. The American Cancer Society and the National Cancer Institute have found that cancer of the alimentary tract accounts for one-half of the deaths resulting from cancer in the United States.

In 1949, Hoerr, Bliss, and Kauffman [1] presented an interesting and provocative study concerning the use of the guaiac test as a screening procedure for the detection of gastrointestinal cancer. These authors based their study on stool specimens collected from unselected hospitalized patients and suggested a simple method of stool analysis with the use of guaiac reagent. They expressed the opinion that the guaiac test is a satisfactory screening procedure in the detection of occult bleeding, because it is not highly sensitive and therefore does not require the use of a meat-free diet. The authors further suggested the use of this test as a routine office procedure.

It is the purpose of this report to present a follow-up study of this procedure as applied to office practice and to determine whether the test has practical application as a screening procedure for gastrointestinal bleeding caused by cancer of the alimentary tract.

THEORETICAL BACKGROUND

Since 1864, when van Deen [2] first used guaiac reagent for the detection of blood, this reagent has been widely used in several modified and refined procedures. However, after Adler and Adler [3] developed the benzidine test, in 1904, and especially after it was refined by Gregersen,[4] in 1919, it became apparent that the guaiac test was not particularly sensitive for the detection of occult blood. As other more sensitive tests were developed, such as phenolphthalein, orthotolidine, ferrocyanide, and spectroscopy, the guaiac test fell into general disuse. It was no longer considered sensitive enough for practical application.

Several articles have appeared in the literature describing comparisons of the sensitivity of the various tests for the detection of occult blood. The guaiac test has generally been considered the least sensitive. Peranio and Bruger [5] recently reported their studies of the comparative sensitivity of the orthotolidine, benzidine, phenolphthalein, and guaiac tests on the feces of normal subjects who ingested measured amounts of blood. They found that, when their subjects were placed on a meat-free diet and given 1.0 cc. of blood, the orthotolidine test would give a positive reaction but that the others would not. When 5.0 cc. of blood was given, the benzidine and phenolphthalein reactions also became positive but not the guaiac reaction. It was necessary, however, to feed their subjects 20 cc. of blood before the result of the guaiac test also became positive; even when their subjects were placed on a regular diet, the result of the guaiac test did not become positive unless they were also fed 2 to 3 cc. of whole blood.

Schiff and co-workers [6] found that, when subjects were placed on an unrestricted diet, 2 out of 14 stools gave positive guaiac reactions. A further survey of the literature, including seven separate studies,[7] indicates that, with an unrestricted diet, it requires 0.5 to 10.0 cc. or more of ingested blood to produce a positive guaiac reaction of the stool.

In searching for a test that might be applicable to the detection of occult blood in unselected patients on a general diet, one could not help favoring this least sensitive procedure, the guaiac test. Its critical reaction point appears to lie close to, but just under, positive, in the normal patient on an average diet. On theoretical grounds, based on the literature, one might expect to find that about 15% of unselected patients would have positive guaiac reactions with their accustomed diets and that the other 85% would have negative reactions unless they were bleeding into the gastrointestinal tract in quantities of 0.5 cc to 10.0 cc. of blood. Other factors, however, enter into this expectation and must be considered in any survey study of bleeding.

First, we have considered primarily bleeding from the upper intestinal tract. Bramkamp[8] has demonstrated that it takes 90 times more blood to give a positive reaction when it is ingested orally than when it is mixed directly with the feces. These authors expressed the belief that pancreatic digestion accounts for this difference. Thus, one might expect to detect small amounts of blood lost from lesions in the colon or rectum much more readily than from lesions in or above the duodenum.

Second, the possible ingestion of such interfering substances as sulfonamides, salicylates, bismuth subnitrate, bromides, or potassium permanganate is an important factor. Gettler and Kaye[9] have reported on the influence of these substances on results of tests for occult blood.

Third, of course, the amount of meat the patient has ingested is a factor. Cowie[7d] has indicated that cooked meats seldom give a positive guaiac reaction, but 20 gm. or more of uncooked beef in the diet will produce guaiac-positive stools. White[7e] has stated that the guaiac test often gives negative results when ¼ to ½ lb. (113 to 227 gm.) of meat has been ingested. It would be anticipated that the patients who had eaten large quantities of meat the day or two prior to examination might be expected to have a positive guaiac reaction. Schiff and co-workers[6] found that stools from patients ingesting 250 cc. of blood may give positive reactions for as long as 10 days.

PROCEDURE AND CLINICAL MATERIAL

In this study the guaiac test was performed as recommended by Hoerr,[1] with the use of feces wiped from the finger cot after examination of the rectum. The group of patients consisted of the first thousand who were interviewed and examined during 1950 in our office. These patients were adults of both sexes who either were new patients or had returned for annual or routine examinations. Each patient also was subjected to the usual laboratory studies, including a complete blood cell count, determination of sedimentation rate, urinalysis, serologic tests, and fluoroscopic examination of the chest; many were studied in the laboratory for other conditions relative to their complaints. All patients were on their accustomed diets at the time of their examinations. The guaiac test was not used as the sole determinant as regards further studies of the gastrointestinal tract; reliance was placed primarily on clinical judgment. However, all patients who exhibited positive guaiac reactions were requested to submit stool specimens for benzidine testing after a three-day meat-free diet. Some patients who had negative guaiac reactions were nevertheless given benzidine tests when it was felt that such a procedure was indicated.

Thus, the patients were studied primarily on the basis of their clinical symptoms and findings according to the custom of office practice. We have attempted to apply the results of the guaiac test in this group in an unbiased manner and to check the ultimate findings against the reaction in order to evalute it as a screening procedure. The patients have been followed now for a period of one year in order that we might obtain any evidence of disease that was not manifest at the time of initial examination. Although some patients have been "lost," the group remains essentially intact.

GUAIAC-POSITIVE GROUP

There were 152 patients, or 15.2% of the total group of patients examined, who had positive guaiac reactions on routine rectal smear examinations. All these patients were requested to go on a meat-free diet for three days and then to submit a stool specimen for benzidine testing. Forty-one of these patients (27%) failed to cooperate by submitting such a specimen even after follow-up letters had been sent to them. This was somewhat of a surprise but seems to point out further the difficulties involved in testing large groups of persons for occult blood in the stool. It is not a test that enjoys much popularity with patients. The majority of patients who did not cooperate in this test were those who had presented no gastrointestinal complaint and in whom there was no evidence of gastrointestinal disease other than a positive guaiac reaction.

Of the 111 remaining patients whose stools were subjected to the benzidine test, 25 (22.5%) were found to have positive reactions. In this group a variety of bleeding gastrointestinal disorders came to light on physical, roentgenographic, and proctoscopic examinations. It is of particular interest that there were six instances of cancer of the gastrointestinal tract in this group. All were present in the large bowel. Four patients had frank adenocarcinomas; one patient had a diffuse degenerating polyposis of the colon, and the sixth patient had a lymphosarcoma that had invaded and ulcerated into the large bowel.

A further analysis of the 152 patients who exhibited positive guaiac stools revealed that 66 (43%) had some definite disorder of the alimentary tract. Five other patients were thought to have a definite disorder, but no diagnosis could be established. No disease was found in 74 (48%) patients, and in 7 others there was inadequate patient cooperation to permit a satisfactory conclusion. It is of further interest that, of these 152 patients, only 84, or 55%, disclosed any symptoms referable to the alimentary tract in their histories.

Among the 1,000 patients examined there were 48 in whom the application of the guaiac test procedure failed. All the failures resulted from an inability to obtain a satisfactory stool specimen on the examining finger cot. One patient in this group was found to have a benign rectal polyp.

GUAIAC-NEGATIVE GROUP

Eight hundred, or 80% of all the patients tested, had negative guaiac reactions. As with all the patients included in this study, each patient was evaluated regardless of the outcome of the guaiac test. Almost 49%, or 389 of the patients of the guaiac-negative group, had some complaint referable to the gastrointestinal tract. Only 94 of these patients exhibited evidence of a disorder of the gastrointestinal tract on physical examination. X-ray studies of the intestinal tract and/or proctoscopic examinations were felt to be indicated and were performed on 255 of the 389 patients who presented such complaints. A total of 165 instances of organic disorder were found in the total guaiac-negative group of 800 patients, and 154 patients in this group were found to have functional disorders to account for their symptoms. Some of the patients who had organic disorders and who had guaiac-negative stools were nevertheless found to have occult blood in the stools when subjected to the benzidine test.

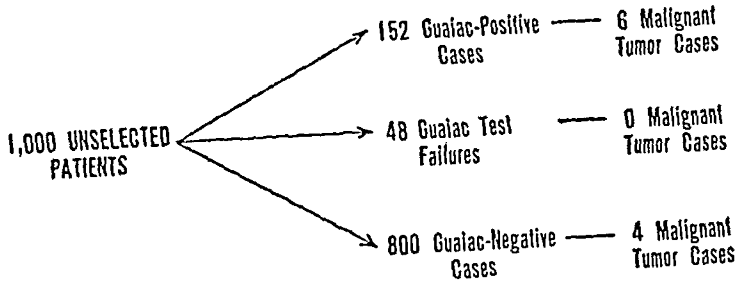
[9] Gettler, A. O., and Kaye, S.: The Phenolphthalein Test for the Detection of "Occult" Blood, Am. J. Clin. Path., Tech. Sect. 7: 77, 1943.

Since the primary interest in this report is concerned with the detection of malignant lesions, we do not feel that a report of other lesions found is appropriate here. Suffice it to state that the commonest disorders found were hemorrhoids and peptic ulcers. In this guaiac-negative group, however, four cases of cancer of the intestinal tract were found. In addition, two patients were found to have well-developed polyps, which, however, had not undergone malignant degeneration.

COMPARISON OF GUAIAC-POSITIVE AND GUAIAC-NEGATIVE GROUPS

Among the 1,000 patients comprising this study, 10 were found to have cancer of the alimentary tract. When the feces of these patients were tested with the guaiac method, four were found to be negative and six positive. A breakdown of the group is indicated in the accompanying figure.



Summary of the incidence of malignant tumors found in 1,000 unselected patients subjected to the guaiac test.

In spite of the theoretical background suggesting the practicability of employing the guaiac test as a screening procedure for occult blood, a comparison of the incidence of malignant disease in the patients studied rather clearly indicates that the test is unreliable for this type of problem. Gastroenterologists and others interested in the detection of malignant tumors of the alimentary tract have generally not been enthusiastic about the employment of occult blood tests. The studies of many investigators have clearly indicated that malignant tumors of the alimentary tract can best be detected by roentgenogram, the sigmoidoscope, and the rectal digital examination. A feeling of security cannot be warranted by a negative occult blood reaction when one is searching for malignant disease. Certainly the premalignant lesions are even less likely to be detected by this method alone.

SUMMARY AND CONCLUSION

A renewed interest in the guaiac test has recently been expressed. The application of this test for the detection of occult bleeding in patients on an unselected diet shows promise on theoretical grounds. A favorable clinical report has appeared in the literature.

In this study an attempt was made to apply the guaiac test to a large group of unselected patients encountered in routine office practice with particular interest in the detection of malignant lesions of the alimentary tract. This was done to determine whether the guaiac test had merit as a screening procedure.

The test itself is particularly easy to perform and requires little time and equipment. The patient need not be on a special diet, and therefore the test can be applied to almost all patients examined in the physician's office.

Unfortunately, however, in the group of 1,000 patients so tested, there were 4 patients with frank malignant lesions of the alimentary tract who did not have guaiac-positive stools as opposed to 6 patients with similar malignant lesions who did have guaiac-positive stools.

We therefore feel justified in condemning the use of this test as a screening procedure for the detection of malignant or premalignant diseases of the alimentary tract. While the various tests for occult blood in the feces undoubtedly have some merit in special situations, we heartily agree that the carefully taken history, the complete physical examination, x-ray studies, and the proctoscopic examination will disclose the presence of most malignant and premalignant diseases of the alimentary tract. So far, there does not seem to be a satisfactory shortcut.

We do not intend that this report should be construed to be a condemnation of occult blood tests in general nor the guaiac test in particular. When these tests are employed as an adjunct to clinical study and interpretation, we believe they have meaning; if they are used merely as a starting point for further study in screening patients, we believe the results will be most disappointing.

324 E. Wisconsin Ave. (Dr. Mason).

Brachial Plexus Syndromes.—There is certainly no one cause for the variety of symptoms which have been from time to time attributed to pressure on the brachial plexus at the root of the neck. Equally certainly, the results of operations designed to relieve such pressure have not led to the survival of much enthusiasm for exploration of the plexus in any but the more uncritical minds. Even when a nervous syndrome is associated with a true cervical rib, removal of the rib appears all too often to do no more than perhaps to arrest the syndrome, and patients with even the largest cervical ribs often show no demonstrable evidence of local pressure when their lowest trunks are exposed. The discovery of a frank neuroma, though not unknown, is quite rare, in contrast with the known local effects of pressure on nerves in other regions.

The story of the treatment of such symptoms in patients who have no demonstrable cervical rib is a sorry record of uncritical, speculative theory despite much really careful observation. As a history of "arm-chair" pathology, the exposition of the scalenus anterior syndrome, of costo-clavicular compression, of abnormal fibrous bands and of unexplained and unmeasured hypertrophy of scalene muscles must have few equals, apart from the history of surgical thought about corresponding syndromes in the lower limb. These theories, just like many discarded concepts of backache and sciatica, were based either on equivocal eponymous physical signs or on attractive speculations on too few operation findings. The physical signs were usually interpreted without reference to an adequate series of normal controls, and the operations without reference to the dissecting room. The recent demolition of most of the accepted clinical "proofs" of compression in the neck has cleared away a good deal of ill-founded theory.—D. Ll. Griffiths, M.D., The Thoracic Inlet, *Journal o Bone and Joint Surgery,* May, 1952.

RESULTS OF EXPLORATION IN PATIENTS WITH CLINICAL DIAGNOSIS OF SUBDURAL HEMATOMA

Philip S. Bergman, M.D., Morton Nathanson, M.D.
and
E. D. Friedman, M.D., New York

Medical literature contains many descriptions of the clinical features and operative findings in cases of subdural hematoma.[1] The criteria for diagnosis, however, are usually discussed only in terms of proved subdural hematoma. Little attention has been directed to cases in which a subdural hematoma was suspected clinically but was not found at operation. It is our chief purpose in this report to compare two such groups in order to evaluate better the diagnostic and prognostic features of this important clinical entity.

Another aspect of this disorder that has received relatively little consideration is the clinical course following surgical treatment. It is often the impression of those not intimately connected with neurological or neurosurgical services that recovery is to be expected after removal of a subdural clot. We shall show that this conception, while sometimes true in the individual case, cannot be applied to subdural hematomas in general.

CLINICAL MATERIAL STUDIED

One hundred patients admitted to the Third and Fourth Neurological Divisions of Bellevue Hospital (New York University Division) from 1948 through 1950 were studied. These represented all the patients during this three-year period in whom the diagnosis of subdural hematoma was considered seriously enough to warrant bilateral trephination or other definitive diagnostic procedures. The age of the patients ranged from 24 to 77 years. All but a few were examined by at least one of the authors. Of the 100 patients, 67 proved to have subdural hematomas or hygromas by trephination, and one was found unexpectedly at postmortem examination. These will be referred to as the "positive group." In the remaining 33 patients, subdural hematoma was excluded by trephination in 27 and by angiography in 6. These will be referred to as the "negative group." In general, the basis of the presumptive diagnosis was a combination of (1) a history or other evidence of head trauma, (2) mental changes, and (3) an unfavorable clinical course.

The material on which this study was made consisted of patients admitted to a large general hospital, including a disproportionately large psychiatric division. Many of these patients entered the hospital in a moribund condition or were out of contact in other respects, so that an accurate history could not always be obtained. A great many had had previous admissions for alcoholism, head injuries, and other disorders. The following features were investigated: (1) clinical course prior to operation, (2) operative findings, and (3) postoperative course.

CLINICAL FEATURES

Reason for Admission.—Of the entire series, 76% of the patients were admitted to the hospital because of changes in behavior or disturbances in the state of consciousness.[2] This preponderance of mental symptoms may be related to the fact that the psychiatric division accounts for more than one-third of all patients admitted to Bellevue Hospital. Eighty-one per cent of the positive group and 61% of the negative group were admitted for mental changes of relatively recent origin.

Only 16% in the entire group were admitted specifically for head injuries per se. The remainder of the patients came to the hospital because of seizures (5%), headache (2%), and hemiparesis (1%). Analysis of these features in the two groups failed to show significant differences.

History.—Trauma: There was a history or external evidence of head injury in every patient. Histories of alcoholism and the scars of old head injuries were common.

Seizures: Thirty per cent of the entire group had convulsions at some time prior to operation. Half of these had generalized seizures and half focal attacks. There was no significant difference between the two groups in respect to the number of patients with seizures or the nature of the attacks.

Examination.—State of Consciousness: On admission, less than one-third of the entire series were considered fully alert, the others showing various degrees of disturbance of consciousness. In this respect there were no differences between the two groups, but it is interesting to note that about one-fifth (19%) of the positive group were restless, often requiring mechanical restraint, whereas restlessness was not noted in any patient of the negative group.

Mental State on Admission: The patients were classified as (*a*) those with an organic mental syndrome (50%), (*b*) those whose mental state was clear (5%), and (*c*) patients with whom no verbal contact could be established because of unconsciousness, aphasia, or psychotic behavior (45%). Comparison of the two groups again failed to reveal any significant differences.

Neurological Findings: 1. Pupils. The pupils were considered abnormal (definite inequality or fixation in miosis or mydriasis) in 27% of the entire group, with no appreciable difference between the positive and negative

[2] They were found by their families or associates to be lethargic, acting peculiarly, or unable to speak as well as before. Sometimes they were found wandering, dazed, about the streets and were brought in by the police or ambulances as drunk or psychotic. The disturbances in consciousness varied from drowsiness to coma.

cases. Unilateral and bilateral pupillary abnormality also occurred equally in both groups. Seventeen patients (25%) of the positive group showed a dilated pupil on the side of the hematoma. Two patients, however, had dilated pupils on the side opposite the lesion, and in one of these the dilated pupil became smaller immediately after removal of the hematoma. Similar findings in regard to the pupils were reported by Echlin.[1b]

2. Eyegrounds. Papilledema, with or without retinal hemorrhages, was present in 15% of the entire series, but it occurred over three times as often in those with subdural hematoma (21%) as in those without it (6%).

3. Other neurological signs. Of all the localizing neurological signs, including hemianopsia, hemiparesis, hemisensory defect, focal seizures, reflex inequality, aphasia, and eye signs (noted above), only in respect to aphasia was there a marked difference between the two groups; four times as many in the positive group had aphasia. Because of the mental changes and disturbed states of consciousness, however, the actual number of patients with aphasia could not be accurately determined. Therefore, no significance could be attached to this apparent difference.

4. Value of signs in determining laterality of the lesion. As an indicator of the side of the pathological process, unilateral signs were reliable in only half (49%), the cases of one-sided subdural hematoma; in the remainder they were on the wrong side (4%), bilateral (22%), or absent (27%). Conversely, when hematomas were found on both sides, bilateral signs were present in only 26%, whereas they were unilateral in 48% and absent in the remaining 26%. In this series of patients, then, unilateral and bilateral subdural hematomas could not be differentiated on the basis of the neurological findings, nor could the side of a single hematoma be predicted accurately.

Laboratory Findings: 1. The cerebrospinal fluid was examined in every case. Some abnormality (elevated pressure, blood, xanthochromia, increased cells, or high protein) was found in 82% of all the cases. Normal fluid was encountered in only 10% of the positive group, whereas 26% of those without subdural hematoma had no abnormality. The major abnormalities (in over 80% of the cases) consisted of blood or xanthochromia (50%) and increased pressure (35%). The type of abnormality had no relation to the presence or absence of subdural hematoma. It should be emphasized that subdural hematomas were found even when the cerebrospinal fluid was completely normal.

2. Electroencephalograms were performed in 21 patients, 14 in the positive group and 7 in the negative group. The electroencephalographic findings were not specific for any type of pathological change, and similar records occurred in both groups. Most of the tracings contained unilateral or bilateral slow wave foci, with a localization usually corroborating the clinical or operative findings. Only one record was within normal limits (a proved subdural hematoma). Reduction of alpha activity in the region of the lesion, often regarded as characteristic of subdural hematoma, did not constitute a prominent feature of the records. Generally speaking, the greater the damage to the underlying brain, the greater the electroencephalographic abnormality; the presence or absence of subdural hematoma made no remarkable difference in the record.

3. Carotid angiography was performed in 12 cases, 6 in each group.[3] In our cases, the angiographic picture was characteristic when subdural hematoma was present and equally reliable in excluding it. In one patient, the postoperative angiogram showed that a previously demonstrated abnormality had disappeared.

Preoperative Course.—The only significant feature of the preoperative course in the two groups was fluctuation in the clinical picture, particularly the state of consciousness. Definite fluctuation occurred five times as often in the positive as in the negative group. Twenty-nine per cent of the patients with subdural hematomas had a fluctuating course, whereas only 6% of the negative group showed such variations.

The vast majority of patients of the entire series were operated on (or subjected to angiography) because of increasing disturbance of consciousness or failure to improve (95%); there were no appreciable differences between the two categories. The remainder (5%) improved to a great extent, but in two instances angiography revealed the presence of a subdural hematoma and trephination was carried out. In one of these cases, despite satisfactory clinical improvement, progressive displacement of a calcified pineal gland led to angiography and operation.

OPERATIVE FINDINGS

Of the entire group, unilateral or bilateral subdural hematomas were seen at operation in 67, and in one case postmortem examination disclosed a previously unsuspected clot. One-quarter of these patients also had other brain lesions, which could be seen well enough to be described by the surgeon at the time of trephination. These abnormalities included contusions, lacerations, subarachnoid bleeding, epidural clot, and intracerebral hemorrhage. The limited field of vision provided by burr holes, however, makes it probable that the actual incidence of associated lesions was much higher.

In the 33 cases of the negative group, both the surgeon's report and subsequent developments (clinical course, pneumoencephalography, or postmortem examination) indicated that no subdural hematoma was present. Some of the brains in these cases appeared normal to the surgeon, but in most of them (68%) laceration, contusion, congestion, subarachnoid hemorrhage, cerebral atrophy, arachnoiditis, or other lesions were discernible beneath the trephine openings or became evident on subsequent air encephalographic examination.

Thirty-eight of the subdural hematomas were considered recent by the surgeon on the basis of the observation of fresh, unchanged blood, recently clotted blood, or the absence of organization or membrane formation. Twenty-eight subdural hematomas were judged to be old, because of the color of the blood and the state of organization.

---

[3] The angiographic examinations were made by Dr. Joseph M. Stein, who has made the detailed findings, indications, and technique the subject of a separate report (Stein, J. M.: Cerebral Angiography in Subdural Hematoma, Neurology, to be published).

[4] Deleted on proof.

An attempt was made to correlate the time between injury and operation and the surgeon's estimate of the age of the subdural hematoma. There was generally a significant relationship in cases of recent subdural hematoma. No "fresh" subdural clot was found in a patient whose lesion was two months old or more, and in only one was the lesion older than one month. In the "old" subdural hematomas, however, the correlation was not good, and the age of the lesion, according to the histories available, varied between one week and eight months. Munro[1a] has pointed out that the visual signs used to estimate the age of these lesions are not reliable.

POSTOPERATIVE COURSE

Of the group with subdural hematoma, 47% recovered sufficiently to be discharged to their homes. Twenty per cent required commitment to state mental hospitals or were discharged in the custody of their families because they failed to improve during the month after operation. Twenty-three per cent died, presumably as a result of their cerebral lesions or of other, though related, causes. Thus over half of these patients, with proved subdural hematomas successfully removed, either died or remained severely disabled. In five postmortem examinations, no cause of death aside from the brain lesions could be ascertained, so that these deaths, as far as we know, occurred as a result of head injuries and their complications. The mortality rate was only slightly higher (40%) in the group with fresh subdural hematomas than in those with older lesions (34%).

In the negative group, 36% were discharged to their homes improved, 30% were committed or discharged in custody because of failure to improve, and 34% died. Although a smaller proportion of the patients with subdural hematoma recovered, the over-all mortality and morbidity rates of the two groups were about the same.

Further analysis shows that complications (contusion, lacerations, and epidural hemorrhage) increased the mortality from subdural hematoma, since 47% of these patients died, whereas, in cases in which the brain underlying the subdural hematoma looked normal to the surgeon, the mortality rate was only 20%. In the negative group, the mortality in the presence of complications such as contusion or lacerations was only 25%. Thus, when a subdural clot is found in association with lesions of the brain itself, the prognosis is poor, even with successful evacuation of the hematoma.

In considering the immediate results of operation for subdural hematoma, we made a study of the time consciousness returned or improved after operation. In the positive group half (51%) of the patients who were destined eventually to live recovered consciousness within 24 hours. The remainder improved more slowly over the next few days, weeks, or even months. It is significant, however, that 24% of the negative group also recovered consciousness within 24 hours after operation or angiography, even though no subdural hematoma could be found. We cannot explain this coincidence, but it suggests that the natural course of the disease may play a more important role than is generally assumed.

COMMENT

From the data presented several points seem worthy of emphasis. First, the prognosis after successful removal of a subdural hematoma should always be guarded. This opinion is supported by the fact that the morbidity and mortality rates in the negative group were proportionately as high as in the positive group. Since the history and clinical course in both the positive and negative groups were so much alike, we cannot assume that the subdural clot per se was the predominant factor in causing death or even the significant clinical signs. It seems probable that the determining factor leading to death and disability is disease of the brain itself, whether this disease was acquired at the time of injury or existed before then. Essentially the same conclusion was reached by Browder and Rabiner[5] from the study of pathological material. A fair assessment of prognosis must consider both lesions, not only the obvious, removable, and therefore deceptive, subdural clot.

Although abnormalities in the state of consciousness are, of course, not pathognomonic for this condition, when they exist in combination with a history or other evidence of head trauma they constitute the only valuable diagnostic sign. This criterion led to a correct diagnosis in 68% of the entire series, which compares well with the diagnosis of other neurological entities.

Neurological signs, such as pupillary changes, aphasia, and hemiparesis, did not occur with sufficient frequency to be reliable. These signs probably reflect brain damage incurred by the trauma rather than pressure produced by the clot.

Reliance could not be placed on lateralizing signs, in view of the frequency of their occurrence in the group of patients without subdural hematoma. The number of hematomas proved to be bilateral or on the unsuspected side justifies the practice of performing bilateral trephinations in every case.

Two general schools of thought exist in regard to the electroencephalographic picture, characterized by reduction of alpha activity over the hematoma. The second believes that subdural hematoma may give rise to a wide variety of nonspecific electroencephalographic patterns, including the alpha "suppression," but also points out that areas of reduced alpha may appear in other pathological states. In our cases, electroencephalography was of no value in differentiating patients with subdural hematoma from those who had head injuries without subdurals. With one exception, the electroencephalograms were all abnormal. The finding that the severity of electroencephalographic changes was proportional to the severity of the damage to the underlying brain agrees with the conclusions of Kaplan, Huber, and Browder[6] and is in accord with experimental studies on the electrical activity of the brain following mechanical injury.[7]

[7] Cohn, R.: Subdural Hematoma: An Experimental Study, Arch. Neurol. & Psychiat. 59: 360-367 (March) 1948. Ulett, G.: Electroencephalogram of Dogs with Experimental Space-Occupying Intracranial Lesions, ibid. 54: 141-149 (Aug.) 1945.

The results of this portion of the study suggested that subdural hematoma does not give rise to a characteristic electroencephalographic pattern and that distinction between the various types of brain injury cannot be made by this means.

SUMMARY

1. One hundred consecutive cases of suspected subdural hematoma, occurring during a three year period, were reviewed. A comparison was made between two groups, 67 patients who had subdural hematomas and 33 who did not.

2. No reliable clinical features distinguished the two groups. When we used as criteria the combination of head injury, changes in consciousness, and failure to improve, the suspected diagnosis proved correct in two-thirds of the cases.

3. The number of deaths among the patients without subdural hematoma was proportionately as high as in those patients with subdural hematoma. Also, there was little difference in the incidence of permanent disability in both groups.

4. Disease of the brain itself, whether or not it was due to injury, was probably the chief determinant of mortality and morbidity.

FAMILIAL AUTONOMIC DYSFUNCTION

Conrad M. Riley, M.D., New York

Up to 1949 there had appeared several isolated case reports [1] of what now seem to be examples of a definite clinical entity. This is characterized by evidences of vegetative dysfunction, such as excessive perspiration, drooling, erythematous blotching of the skin, intermittent hypertension, and defective lacrimation; hyporeflexia and emotional instability are also present. In 1949 my co-workers and I reported five illustrative cases.[2]

Since then our experience with the condition has grown with new cases and repeated observations on old cases. Other hospitals and physicians have made available the records of additional cases, so that we are now able to present a more definitive picture of the condition, based on a total of 33 cases. Their sources are shown in table 1.

TABLE 1.—*Sources of Thirty-Three Cases*

Hospital or Physician	City	No. of Cases
Babies Hospital	New York	11
Mount Sinai Hospital	New York	5
New York Hospital	New York	4
Children's Hospital	Boston	2
Dr. H. F. Saunders	Cleveland	2
Dr. H. S. Altman	New York	1
Dr V. Tappan	Tucson	1
Engel and Aring [1b]	Cincinnati	1
Bellevue Hospital	New York	1
Beth Israel Hospital	New York	3 *
Dr. F. A. Disney	Rochester, N. Y.	2

* Two of these cases have been reported in the literature (Aronson, N.; Stern, G. S., and Cohlan, S. Q.: Paroxysmal Hypertension Simulating Pheochromocytoma, Pediatrics 8:661, 1951).

CLINICAL FEATURES

In table 2 the common features are listed and their frequency in this series shown. These are arranged in two groups, the first (group A) being made up of those that are almost constant and the second (group B) of those that have occurred frequently enough to make them appear relevant.

Group A.—1. Race: All the patients who showed the full syndrome have been of Jewish extraction. We have seen three persons of other races who failed to produce tears when crying, but none of these has shown any of the other features.

TABLE 2.—*Occurrence of Features in Thirty-Three Cases*

Feature	No. of Cases with Information Available	Cases with Feature	
		No.	%
GROUP A			
1. Jewish extraction	33	33	100
2. Defective lacrimation	33	33	100
3. Skin blotching	31	30	97
4. Excessive perspiration	31	31	100
5. Drooling	27	27	100
6. Emotional instability	30	30	100
7. Motor incoordination	27	27	100
8. Hyporeflexia	31	30	97
9. Relative indifference to pain	22	22	100
GROUP B			
1. Hypertension	27	23	85
2. Cyclic vomiting	30	19	63
3. Frequent pulmonary infection	31	23	74
4. Frequent unexplained fever	24	16	67
5. Breath-holding spells in infancy	22	16	73
6. Urinary frequency	24	18	75
7. Mental retardation	31	17	55
8. Convulsions	32	16	50
9. Corneal ulceration	31	11	35

2. Defective Lacrimation: All the patients have failed to produce tears in normal fashion when crying. Usually this has been absolute, but in one or two cases an occasional tear has been seen. The eyes are not dry, and tear production seems adequate to maintain corneal health in most instances. The exceptions to this will be discussed in group B. It has been difficult to evaluate corneal sensation accurately, but in some cases complete anesthesia has been present and in others sensation seems to be diminished.

3. Skin Blotching: In all but one of the group erythematous, sharply defined blotches appeared on the face, shoulders, and upper part of the thorax when the patient was excited or was eating. These would disappear

within 10 to 15 minutes after withdrawal of the stimulus. They were usually (but not always, as will be shown below) symmetrical and tended to recur in the same areas. The one patient in whom this was not observed was 14 months old and showed only mottling of the extremities when excited.

4. Excessive Perspiration: All the patients perspired excessively, especially under conditions of excitement. In one patient in whom the skin blotching was asymmetrical, perspiration was also asymmetrical, particularly noticeable on the forehead.[1]

5. Drooling: In all about whom adequate information was available, drooling continued long past infancy. This was exaggerated during excitement.

6. Emotional Instability: Their emotional make-up was similar, in that they all responded to minor emotional stimuli in an "all or none" fashion. This made their relationship with other persons very difficult, and their management in the home has proved a major problem. Their span of attention is short, and usually their behavior is unpredictable.

7. Motor Incoordination: These children have all been awkward with their hands and have a peculiar shuffling gait. It is not possible to demonstrate regularly any specific neurological abnormalities except for the hyporeflexia to be discussed. They also have a characteristic thickening of speech.

8. Hyporeflexia: In most of the patients it has been impossible to elicit any deep tendon reflexes. In a few, however, these reflexes were obtained with difficulty but were definitely hypoactive. In two patients it was reported that reflexes could be elicited on some occasions and not on others. In only one patient were reflexes reported to be normal.

9. Relative Indifference to Pain: Information with regard to pain sensitivity was available in only 22 cases, and in each of these a relative indifference was present. Because of the strong emotional response of the patients to any stimulus, it was difficult to evaluate their response to pain itself. The abnormality was called to my attention by the fact that, when a limb was immersed in ice water for a cold pressor test after previous conditioning to the procedure, there was no complaint of pain even after 60 seconds. Subsequent questioning of parents revealed in many instances that their children did not seem to mind minor bruises. One child, in fact, had a broken wrist discovered only by the presence of swelling. This is not true anesthesia or hypesthesia, since the patients recognize pinpricks readily.

Group B.—In the next group of features are those which, although frequently dramatic and often associated with complaints, have not been present consistently.

1. Hypertension: Intermittent hypertension was a frequent finding evident in about 85% of the patients in whom it could be evaluated. It occurred in response to excitement, and not infrequently a resting blood pressure of 100/60 mm. of mercury would rise under the threat of venipuncture to 160/130 mm. Many of the patients who exhibited recurrent attacks of vomiting had hypertension persisting throughout the episode, with the blood pressure returning to normal levels as the vomiting subsided. One patient at times manifested such severe degrees of hypotension that he had "blackout spells." Recently this patient had bouts of vomiting associated with the expected hypertension and followed by severe and persistent hypotension associated with a shock-like picture; this seemed to be modified by treatment with cortisone. The hypertension has been so prominent that in five cases surgical exploration for pheochromocytoma was undertaken.

2. Cyclic Vomiting: Almost two-thirds of the patients had severe attacks of vomiting recurring at intervals ranging in different patients from a few days to several months. Associated with these attacks were personality changes of pronounced degree. A previously cheerful and cooperative child would become sullen, withdrawn, and destructive toward himself and others. Usually the vomiting and personality change would terminate abruptly after two to three days. At times these attacks appeared to be induced by known emotional upsets; at other times there was no apparent inciting factor. This was one of the most distressing and incapacitating features.

3. Frequent Pulmonary Infection: In 23 of the group, repeated bronchitis or bronchopneumonia caused an inordinate amount of hospitalization. In several of the children this began in the early months of life and was the basis for a tentative diagnosis of cystic fibrosis of the pancreas, for which condition careful studies were made. In those who have survived, the frequency of pulmonary infection has diminished with advancing years.

4. Frequent Unexplained Fever: Two-thirds of the patients in whom the facts were known had frequent fever that was not readily explainable. Before the diagnosis was made, this fever had been attributed in some instances to a disturbance of the "temperature-regulating center."

5. Breath-Holding Spells in Infancy: Information about this characteristic is available for only 22 patients. Out of these it was found that almost three-quarters gave a history of this phenomenon in the first year of life. When the patients were first seen, at the age of 4 or 5 years, breath-holding had usually been forgotten by the parents; they were reminded only by direct questioning.

6. Urinary Frequency: A large proportion of the children showed urinary frequency, which appeared to be the result of nervous tension rather than real neurogenic disturbance of the bladder.

7. Mental Retardation: Among the first patients in our series many had mental retardation, and it was originally thought that this was a regular feature; but as the series has grown the findings have been less consistent. More than half the patients have shown mental defectiveness; on the other hand, several of those who were not retarded have shown actually superior intellectual endowment.

8. Convulsions: Convulsions have occurred in half the patients. In some cases there has been a history of repeated convulsions, but usually only one or two seizures associated with fever have occurred.

9. Corneal Ulceration: The last clinical manifestation of significance is one that seems to be secondary to one of the cardinal features, defective lacrimation. Although in most instances there was no interference with corneal health, in 11 cases corneal ulcers developed either with slight trauma or after no known trauma. Usually these healed rapidly, but in three patients healing was so unsatisfactory that permanent scarring developed and seriously interfered with vision.

Miscellaneous.—Two other findings have been noted that suggest muscular disturbance secondary to central nervous disorder but that are too infrequent to be considered necessarily part of the picture. Scoliosis has been found in five of the patients. In one of these it was of severe degree. "Pes cavus" has been reported in two cases.

SPECIAL TESTS

The diagnosis of this condition depends for the most part on the observation of the clinical features discussed above. While many exploratory investigations have been carried out in these cases, in general these do not add to an understanding of the disturbance. Signs of basic metabolic disturbance, such as hypoglycemia or electrolyte imbalance, have not been present. Nitrogen retention has been observed only during periods of dehydration associated with vomiting, except in one case, when death appeared to be due to uremia that was thought to result from renal insufficiency secondary to hypertensive episodes, since nephrosclerosis was observed at autopsy. In general, however, chemical abnormalities have not been remarkable.

The result of the cold pressor test has been abnormal when used. If the patient was previously acclimated to the procedure, so that emotional factors did not intrude, there was no change in blood pressure. It is suggested that the indifference to pain previously discussed explains this lack of reaction.

The benzodioxane test[3] has been carried out in four cases. This test could be applied only when high blood pressure was maintained over a considerable period. In several instances a fall in blood pressure resulted with the administration of the drug. However, in contrast to the results occurring in cases of pheochromocytoma, the fall in blood pressure lasted only two to three minutes, whereas with the usual positive result the lowered blood pressure persists for 15 to 20 minutes.

Pneumoencephalograms made in six cases have shown no consistent pathological findings. Electroencephalograms have been recorded in 21 cases. In 16 of these the tracing was reported as abnormal. Often it suggested "convulsive disorder," but there was nothing specific in the findings.

FAMILIAL INCIDENCE

The occurrence of this syndrome in siblings appears to be too frequent to be attributed to chance. Table 3 summarizes the familial incidence. Among the 33 patients there are four pairs of siblings; in addition 7 other offspring appear in their histories to have been afflicted with a similar condition. Considering only the siblings of the index cases (that is, the cases that brought the family to the attention of a physician), there is a total of 33, of whom 11 are known to be or are thought from history to be affected. This proportion is compatible with a mendelian recessive characteristic, but no definite conclusions can be reached in this respect with such a small group. No history has been obtained of similar disorders among parents or collateral relatives. Also, there has been no evidence to date of consanguinity among the parents.

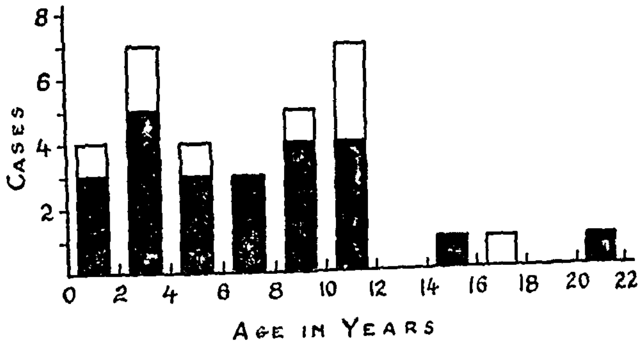
AGE DISTRIBUTION AND MORTALITY

Since the above evidence suggests that this syndrome is congenital in nature, there should be no preponderance of any one age range in a random group. This is borne out by the distribution of ages among the patients of our series as represented in the accompanying figure. The oldest patient is a girl of 20 years; one boy died at 17 years. In all the cases in which a detailed history was available, difficulty was encountered in early infancy. This usually consisted of difficulty in feeding, with the baby appearing to have trouble with swallowing. Abdominal distention was another common complaint. As a result of these features, the babies tended to be poorly nourished during the first year of life.

TABLE 3.—*Familial Distribution*

Total families	28
Total offspring	61
Known cases	32
Probable cases (by history)	7
Families with more than one child	22
Total siblings of index cases	33
Siblings affected or probably affected	11

Also shown in the accompanying figure are the ages at which death occurred in the 10 patients who have died. In eight of these the cause of death was attributed to aspiration pneumonia. In one case it appeared to be due to renal failure as mentioned above, and in the 10th case death occurred at home with a terminal episode of hematemesis.



Distribution of patients by current age (March, 1952) or age at death. The black portion of the bars represents the living and the white portion the dead.

POSTMORTEM FINDINGS

Autopsy has been performed in nine instances. Among these, pathological conditions in the central nervous system have been noted in only two. In one there were multiple abscesses in the brain, which were apparently secondary to aspiration pneumonia and presumably occurred terminally. In the second case, a report of which has been published,[1b] a small cyst was found in the thalamus. The absence of a similar lesion in the other cases suggests that this was an incidental finding.

TREATMENT

Treatment has been limited to efforts to modify the more disturbing manifestations, such as vomiting, hypertension, defective tearing with corneal ulceration, and the extreme emotional instability. Among the agents that have been tried are various types of anticonvulsants and sedatives, autonomic-active drugs, muscle relaxants, dimenhydrinate (dramamine®), and even cortisone; none of these has made any significant difference. The surgical procedure, previously reported,[4] of splitting the tentorium, though followed by temporary improvement, made no lasting difference. Lumbar sympathectomy in one case produced only temporary modification of blood pressure. Psychotherapy has proved unavailing, largely because it has been difficult to establish any real contact with the patient. In one patient whose vomiting was accompanied by an acute psychotic state and persisted for a dangerously long period, electric shock therapy has appeared on several occasions to interrupt the attack; when it was used prophylactically, however, it apparently had no effect. The most radical approach tried in a patient totally incapacitated by the frequency of her vomiting attacks has been prefrontal lobotomy. For almost a month after this procedure the patient did no vomiting but thereafter relapsed into her former state.

This summary of failures is given merely to show the variety of approaches that have been tried. Also, the fact that such heroic approaches seemed justified serves as an index of how disabling the symptoms can be.

COMMENT

The 33 cases summarized in the foregoing presentation have so many features in common that it justifies the concept that they are examples of a real and easily recognizable clinical entity of familial nature. This syndrome is manifested primarily by disturbances in function of the autonomic nervous system.

The syndrome can be recognized with considerable assurance in children over 2 years of age when all the features are evident. In younger children deficient lacrimation, absent reflexes, and skin blotching make the diagnosis fairly certain, especially if associated with a history of feeding difficulty. In the differential diagnosis in the first year of life acrodynia and cystic fibrosis of the pancreas may come up for consideration. In older children, pheochromocytoma or primary psychiatric disorder have had to be ruled out. The presence of all or most of the cardinal features discussed makes the differentiation relatively simple.

There is insufficient evidence to permit one to determine the pathogenesis of the syndrome. The fact that the neurogenic symptoms are so widespread strongly suggests a central rather than a peripheral origin. The presence of autonomic disorder, hyporeflexia, relative indifference to pain, psychic abnormality, and frequently mental retardation make it difficult to localize the disturbed function in any one area of the brain.

The question of the most suitable terminology for the condition has not been easy to settle. In the absence of knowledge of the causes or the pathologicoanatomic changes, a partially descriptive term is proposed that points out the most striking disability: "familial autonomic dysfunction," or, with the use of a Greek derivative to make the title shorter, "familial dysautonomia."

Finally, with the experience gained from this group it seems reasonable to speculate on the possible distribution of cases. All the patients described herein were brought to medical attention because of some incapacitating feature, but no one patient showed all the severe features. It is likely that there are patients with none of the extreme features who might present only behavior problems in childhood or personality problems in adult life. There is nothing in the basic condition incompatible with long life, so that it seems probable that as knowledge of the syndrome becomes more widespread more adult examples of it will be found.

SUMMARY

A composite picture of the syndrome "familial autonomic dysfunction," or, more briefly, "familial dysautonomia," based on 33 cases is presented (table 2). The nearly constant features of the condition are (1) Jewish extraction, (2) defective lacrimation, (3) skin blotching, (4) excessive perspiration, (5) drooling, (6) emotional instability, (7) motor incoordination, (8) hyporeflexia, and (9) relative indifference to pain. Other variable manifestations that have been disabling were present in all cases. It is an easily recognizable entity, not basically lethal, and presumably a congenital disorder of the central nervous system, in which the familial incidence suggests a genetic origin.

Undetected Gastric Ulcer.—Roentgenologic examination is the chief method for the diagnosis of gastric ulcer. However, roentgenologists know well that a certain percentage of gastric ulcers cannot be found even with very careful examination including compression technic with spot films. The number of these apparently undiscoverable ulcers does not alone depend upon the skill and thoroughness of the observer. The number noticed depends greatly upon the number of checks done either by gastroscopy or by exploratory laparotomy. In places where gastroscopy is done only in rare cases, as an exceptional procedure, the patient in whom nothing was found at x-ray examination will be discharged after treatment and nobody may ever discover that in fact he had a gastric ulcer. If gastroscopy is done in every single instance in which a gastric disease is suspected, but in which roentgenologic examination failed to reveal any pathologic change, then quite a few gastric ulcers are found. Therefore it is difficult to compare statistics.

It must not be forgotten that many gastric ulcers cannot be seen at gastroscopy, and thus some ulcers will not be found even when both methods are employed. How frequent such diagnostic failures are we will never know, unless some new third diagnostic method is developed. It is clear that exploration cannot be undertaken routinely and therefore does not constitute such a third method.—R. Schindler, M.D., Large Gastric Ulcers, Not Demonstrable at Roentgenologic Examination, *The Medical Clinics of North America*, July, 1952.

PROBLEM OF EMOTIONAL TRAUMA IN HOSPITAL TREATMENT OF CHILDREN

Katherine Jackson, M.D., Ruth Winkley, A.B., Otto A. Faust, M.D.
and
Ethel G. Cermak, M.D., Albany, N. Y.

The importance of the emotional needs of the child in the hospital, and especially of the child who is to be operated on, has been receiving more attention in recent years by nurses, pediatricians, surgeons, and psychiatrists. The fact that emotional trauma occurs is widely accepted. The definition of the term, however, and the causes and means of prevention of the condition are sometimes inadequately understood. For the purpose of this discussion, emotional trauma will be defined as the intensification of any feeling that may be deleterious to a satisfactory adjustment to life. Feelings that are likely to be involved in the hospital treatment of children are anxiety, suspiciousness, resentment, hostility, inadequacy, insecurity, and a desire to retaliate.

From our study of the psychological aspects of hospitalization, anesthesia, and surgery in a group of children, certain conclusions seem justified concerning the nature, etiology, and prevention of emotional trauma associated with such experiences. The children, whose ages ranged from 3 to 8 years, were admitted to the hospital for tonsillectomy. Before admission, a psychiatric social worker interviewed the mother and the child in the home, obtained a record of the child's behavior, and evaluated his emotional characteristics and his relationship to his parents. A history of dreams and mannerisms was included in an attempt to elicit the presence of repressed feelings. This interview was repeated several times after the operation. Final checks after 18 months are now being made.[1] In most of the children, anesthesia was induced with open-drop vinyl ether (vinethene®) administered by an anesthetist with special interest and experience in dealing with emotional problems.[2]

In this study, a child who was able and willing to cooperate in the hospital procedures, who accepted the usual treatments with a minimum of resistance, and who went through the induction of anesthesia without evidence of serious fear was considered to have met the experience adequately. If during the postoperative interviews no behavior changes were found that indicated the intensification (overt or repressed) of any of the abovementioned negative feelings, it was concluded that the child had suffered little or no emotional trauma.

In this age group, traces of some or all of the negative feelings under consideration are already present. They exist in varying degrees in every child. Thus, it is impossible, at this age, to initiate a new negative feeling by any single experience. Even as threatening an incident as hospitalization and surgery is merely another feeling-experience. It is the combined responsibility of parents, physicians, and hospital personnel to make it a constructive experience or at least to keep its emotional damage to a minimum. In the prevention of emotional trauma in the hospital-anesthesia-surgery experience, there are three important factors: 1. The child must have made a reasonably adequate adjustment to his environment. 2. He must have proper preparation for the specific experience. 3. The experience must be modified to meet the child's endurance. The first of these factors, the adjustment of the child to his environment, depends almost entirely on the relationship between the child and his parents. If he has been wisely loved and adequately supported, he will be trusting and self-assured. If his parents are suspicious or retaliatory, he will be likely to follow this pattern. Just as his physical traits are determined by those of his parents and grandparents, his emotional make-up will largely parallel that of his forebears. The difference is that, while purely physical characteristics are modified only by generations of evolution, any parent can learn to understand and improve his feeling-pattern and pass on to his child a different set of emotional reactions from those he learned from his parents. The importance of this principle lies in the fact that the emotional equipment required for dealing adequately with a hospital experience is no different from that needed in dealing with the other problems of life.

Our experience has shown that the child best able to meet the hospital-anesthesia-surgery situation is the child who is able to trust the physicians and nurses to treat him fairly. He assumes that painful procedures are necessary, are for his own good, and are not punitive. He is willing, therefore, to place himself in the hands of others and expects from them the kindness, understanding, and support to which he is accustomed at home. He is not overwhelmed by his own fear, because he is able to trust someone else who is unafraid. Obviously, such a child must have a firm foundation of trust in his parents, a deep assurance that they are always fair and always consistent in their love. He has already learned that a certain amount of unpleasantness and deprivation are unavoidable in life and that they are not in any way punishment for misbehavior. In the hospital, he expects some unpleasantness and pain and accepts the situation without resentment.

With such a background of preparation for all difficult experiences, preparation for hospitalization is simple. The parents should explain honestly and simply what is going to happen and why. The child's questions should be answered patiently and reassuringly. It is important that the parents avoid communicating to the child any apprehension that they may have. On the other hand, the

[2] Jackson, K.: Psychologic Preparation as a Method of Reducing the Emotional Trauma of Anesthesia in Children, Anesthesiology **12**: 293-300 (May) 1951.

child's fear should be accepted as normal and be neither denied nor ridiculed. In other words, the child should be allowed to be frightened but should be able to look to the adults and find them adequate and unafraid.

The time of admission to the hospital for elective procedures should be determined with regard to the child's emotional state. In case of a death in the family, especially that of a parent or a sibling, or serious marital difficulty between parents, operation should be postponed until the child has made his best adjustment to the situation. Time should also be allowed for his becoming accustomed to school, a new home, a new baby, or a new stepparent before he is sent to the hospital.

Shortly before admission to the hospital, either the family physician or the surgeon should tell the child what is going to be done. If, along with tonsillectomy, any other procedure, even the removal of a tooth or a wart, is anticipated, this should be explained. One of the children in our group had been told by a child who had had a hernia repaired at the time of his tonsillectomy that his tonsils would be taken out through his abdomen. The child's misunderstanding was corrected before surgery, but he had several days of anxiety. Whenever there is a period of anesthesia, a child may become apprehensive about what has been done to him while he was unconscious. Only his trust in his parents and the physician protects him from fantasies of mutilation.

For even the best-prepared child, and especially for the anxious one, considerate treatment in the hospital is necessary if emotional trauma is to be avoided. It might seem that busy nurses and physicians could not possibly meet each child's emotional needs, and it is true that they cannot perfectly replace the parent, but children who have been loved wisely at home develop a self-assurance that makes them less demanding. They need only considerate understanding and they will cooperate. Specific examples of desirable means of administering treatment could be given, but the important factor is the feeling of the adult toward the child, for the person who really has the child's welfare at heart will intuitively choose the least traumatic methods. Lack of experience sometimes leads to minor errors. A student nurse was inadvertently responsible for several days of anxiety in one of our children, because she told him that the catheter through which rectal anesthesia was administered was only "a puppy dog's tail." The child could not remember the catheter being removed. Naturally, not all persons have the emotional maturity, the warmth, or the wisdom to be supportive and understanding; if, however, the child is making a satisfactory adjustment to life in general, he will probably not be seriously disturbed by unenlightened treatment for a few days in the hospital.

The exception to this occurs in separating the very young child from his mother at the time of surgery. When there has been no previous separation, this aspect of the experience is probably the greatest source of trauma. For most children under 4 years of age, it is our observation that no amount of love and understanding will effectively substitute for the mother. When physicians realize how inextricably a child's emotional welfare is bound up with physical welfare, provisions will be made for a parent to remain with the hospitalized child. If only in the interest of physical well-being, a consideration of the child's emotional needs must eventually take precedence over rules, schedules, and the polish on the floor. Certain qualifications must be made to the general statement that a parent should stay with the child hospitalized for tonsillectomy. Since the purpose of the parent's presence is to support the child in a difficult situation, any parent who does not help the child is of no use. In fact, the overanxious parent may add to his child's burden, and, certainly, the parent who overidentifies to the point of hysteria (not a rare occurrence in our study) does the child more harm than good.

In the interest of reducing emotional trauma during the hospital stay, treatments such as enemas and venipunctures should be kept to a minimum. Having anything inserted into the anus, especially by a stranger, is extremely objectionable to most children and should be avoided whenever possible. If the child has learned to hold a thermometer in his mouth, he should be permitted to do so at the hospital. Waking the child at midnight on the preoperative day to take his temperature because the chart calls for a reading seems unkind and unnecessary. A preoperative reading after he has awakened is more informative and less traumatic. Giving unavoidable enemas and taking temperatures are things that can be done by the mother if she is allowed to stay with the child.

Among the children in our group, needles caused the greatest resentment. It was our practice to reduce the use of needles to a minimum, so that we usually were able to protect the child from all but the finger prick for the hemoglobin reading and the atropine injection. The latter was given in the arm rather than in the buttocks, because, early in the study, we found that less resentment was aroused when the child could see what was done. Venipuncture for the Wassermann test, which is required by hospital regulation, was done during anesthesia.

Although this was the usual procedure in our study, an opportunity was afforded to observe reactions to venipunctures in the same children. Another department began research that involved securing several specimens of venous blood, and, before an understanding and agreement could be reached, several children in our group had been used as subjects. The reactions to this experience were more intense than to any other procedure. Most of the children remembered and resented it at the final 18 month check-up. Obviously, it is impossible to avoid venipuncture entirely, but it seems wise to restrict its use to occasions when it is really necessary. It should then be done by persons who have had experience in doing venipunctures. Such experience can be acquired by doing the necessary venipunctures on anesthetized children or on children with "medical" conditions, who are not being subjected to the additional stress of anesthesia and surgery.

The use of a bed with sides is sometimes taken as an insult by children who have outgrown them at home. It is accepted, however, if the sides are explained as a necessary protection against a painful or dangerous fall. The young patient should not be required to stay in bed, especially alone in a room, when he is feeling well. On the day before surgery, he will be happier and more cooperative if he is allowed to go about the ward and play with other children.

The atraumatic administration of anesthesia poses a special problem. Unless precautions are taken, the child is likely to mistake the onset of unconsciousness for impending death and to struggle accordingly. Verbal reassurance alone is ineffective and must be augmented by specific information about the experience and its accompanying sensations. With the method described in an earlier paper,[2] almost all of our children went to sleep without resistance or evidence of serious fear. Exceptions were a few children who gave evidence of previous emotional disturbance; most of these children were under 4 years of age. A few 3-year-old children went to sleep without protest, but they had the advantage of good support and reassurance by a parent or parent substitute during induction of the anesthesia.

The inability of children under 4 years of age to understand and anticipate a threatening experience might suggest the advisability of using some form of basal anesthesia. A few of our children were given thiopental sodium rectally, too few to warrant conclusions concerning its efficacy in preventing emotional trauma. It was noted, however, that the children who went to the operating room asleep showed some postoperative anxiety and doubt about whether their tonsils had really been removed. At the time of emergence from anesthesia, the child again has a great need for the comforting presence of the parents. In fact, even if parents are barred at all other times from the pediatric ward, they should be allowed to be present at the bedside of the awakening child. Even under the best conditions, the child has been through a frightening and threatening experience and needs the immediate assurance that only a mother or father can provide.

Most children come to the hospital with less than perfect intellectual and emotional preparation. Deep-seated anxieties and feelings of insecurity and inadequacy make the prospective experience a real threat to their emotional adjustment to life. To these children, physicians, nurses, and other hospital personnel can render valuable aid. They can supply the love and the support that the child must have if he is to withstand the hospital experience without further emotional damage. The child who is anxious and suspicious is the child who will cry and resist the most, and he is the one who most needs kind treatment. It requires emotional maturity and understanding to be "good" to a belligerent, assaultive child, but the willingness and the ability not to retaliate at such a time will pay dividends in reducing the child's hostility and resistance and in the satisfaction of having made a constructive contribution to his emotional well-being.

DATA

During the two year period of our study, 105 children were observed through the first three postoperative months. At the first interview after the operation, many were found to have been babyish and clinging, to have slept restlessly, or to have adopted substitute or new self-comforting mannerisms. At the end of the three month period, this less acceptable behavior had persisted in 17 children. Some degree of emotional handicap existed in almost all the patients, but whereas 88 of these children survived the experience without evidence of damage, an examination of the emotional background of the 17 who did not is indicated. Correlations are being made in all cases between the emotional factors considered above and earlier potentially traumatic experiences and postoperative behavior changes.

SUMMARY

During two years work on a special study of the psychological aspects of hospitalization, anesthesia, and surgery for children, it was observed that a child is least likely to suffer from emotional trauma if he is well adjusted to a family environment of love, trust, and security. Certain factual preparation is necessary before hospitalization, in order to prepare him for the experience. The time of hospitalization should be chosen according to his emotional balance.

All phases of the experience should be gaged to the child's ability to adjust, and all procedures to which he is subjected should be carried out in a considerate and friendly manner. Painful treatments should be kept to the necessary minimum. In all children, but especially in those who are inadequately equipped for hospital experience, physicians and hospital personnel can, by kindness, understanding, and support, greatly reduce traumatic effects. Of 105 children studied, 17 showed behavior changes at the end of the third postoperative month.

SULFHEMOGLOBINEMIA FOLLOWING HABITUAL USE OF ACETANILID

Telfer B. Reynolds, M.D., London

and

Arnold G. Ware, Ph.D., Los Angeles

There are numerous reports in the older medical literature of cyanosis following the prolonged ingestion of acetanilid;[1] the cyanosis was assumed to be due to the presence of methemoglobin. In 1930, Harrop and Waterfield called attention to the fact that acetanilid poisoning could cause sulfhemoglobinemia.[2] There are a few other reports in the literature of single instances in which this fact was demonstrated.[3] Nevertheless, cyanosis with acetanilid poisoning is still frequently ascribed to methemoglobinemia.

Differentiation between the two pigments is relatively easy by methods now available and is of considerable practical importance, particularly with regard to therapy. Methemoglobin is rapidly reversed to normal

---

From the Department of Medicine, Hammersmith Hospital (Dr. Reynolds); from the departments of medicine and of biochemistry and nutrition of the University of Southern California School of Medicine and the Los Angeles County Hospital (Dr. Ware).

hemoglobin by the enzyme systems in the red blood cell as soon as the offending poison is removed. Treatment of methemoglobinemia of a mild degree is, therefore, often unnecessary. In severe cases, methylene blue (1 to 2 mg. per kilogram), given orally or intravenously, is dramatically effective and may be life-saving. Sulfhemoglobin, on the other hand, is not reversible to hemoglobin, and, once formed, it persists for the life of the red cell. No known treatment is beneficial. Diagnosis is important chiefly because of the implications it carries regarding the patient's drug intake.

Cyanosis that persists after the causative agent is withdrawn is probably due to sulfhemoglobin rather than methemoglobin. Since many patients with this disorder are drug addicts who often obtain supplies by surreptitious means, it is difficult to be certain when drug ingestion has been stopped; therefore, spectroscopic examination of the blood is essential for a definite differentiation. The absorption bands of methemoglobin (630 mμ) and sulfhemoglobin (618 mμ) can be confused when a hand spectroscope is used, but they are easily differentiated after the addition of a small amount of neutral cyanide solution; this dissipates the methemoglobin band, but the sulfhemoglobin band is unaffected. The following case histories of six patients seen during a relatively brief period in the wards of a general hospital indicate that sulfhemoglobinemia and not methemoglobinemia is the usual result of acetanilid overdosage and that acetanilid habituation is still a problem in clinical medicine.

REPORT OF CASES

Case 1.—A 52-year-old white woman was admitted to the Los Angeles County Hospital on July 13, 1950, with the complaint of severe, crushing precordial pain of six hours' duration. The heart was moderately enlarged; the blood pressure was 110/70; and marked cyanosis was present, which did not clear with oxygen inhalation. An electrocardiogram indicated a recent anterior myocardial infarction. Because of the persistent cyanosis, methemoglobinemia was suspected. In the blood sent to the laboratory, an abnormal band in the red spectrum was found, which was thought to be caused by methemoglobin. Eighteen per cent of the total hemoglobin of 14 gm. per 100 cc. (Sahli acid-hematin method) was so affected. This estimate of methemoglobin concentration was made by the method of Chase and associates,[4] which makes use of absorption ratios at appropriate wave lengths. It does not differentiate between methemoglobin and sulfhemoglobin. After repeated questions, the patient admitted taking "some" bromo-seltzer® (2.5 grain [0.16 gm.] of acetanilid and 5 grains [0.32 gm.] of sodium bromide per teaspoonful). Her son stated that she had been taking bromo-seltzer® in large quantities for several years to relieve nervousness, tension, and headaches. She ultimately admitted taking from five to six teaspoonfuls daily, which the son felt was less than she actually used. She denied taking any other medication. The blood bromide level four days after entry was 12.6 mEq. per liter. It was not appreciated that the spectrophotometric method failed to make a distinction between methemoglobin and sulfhemoglobin; accordingly, 7.5 cc. of 1% methylene blue was administered intravenously on July 29. There was no change in the cyanosis, and the methemoglobin level on Aug. 1 was still 16% of the total hemoglobin. Ascorbic acid, 500 mg. daily by mouth for 12 days, failed to lessen the cyanosis. Convalescence from the myocardial infarction was uneventful. The blood bromide level fell to 2.3 mEq. per liter on Aug. 14. At the time of discharge, on Aug. 21, the blood still contained 11% abnormal hemoglobin. The patient specifically stated on admission that she had not been constipated, and this was not a problem during the hospital stay.

COMMENT

In retrospect, the abnormal hemoglobin responsible for the cyanosis was unquestionably sulfhemoglobin. There was no response to reducing agents, and the cyanosis was of long enough duration to exclude the possibility of methemoglobinemia. (The falling blood bromide level proved that bromo-seltzer® ingestion was not continued.) This case illustrates an error in diagnosis leading to unnecessary and ineffective therapy because of the failure to employ the simple cyanide differentiation test. Because of the heart disease, transfusion may have been indicated in an effort to increase the oxygen carrying capacity of the blood. Such treatment rarely would be necessary, since, in none of our patients was more than 20% of the hemoglobin changed to sulfhemoglobin.

Case 2.—A 51-year-old white man was admitted to the Los Angeles County Hospital on Aug. 28, 1950, with diffuse, poorly-described abdominal pain and generalized weakness of several weeks' duration. He was somewhat belligerent and talkative, and his memory seemed poor. There was a pustular acneform eruption over the chest and back. The mucous membranes and lips were deeply cyanotic, and the skin had a pasty, grey appearance. His hospital record extended back to 1943, with numerous clinic visits for multiple, poorly-described complaints, which included headache, weakness, and abdominal and chest pain. On several occasions, cyanosis of the lips had been noted. On one hospital entry in 1948, there was a history of bromo-seltzer® ingestion, and the blood bromide level was 24.2 mEq. per liter. At first the patient denied taking bromo-seltzer,® but gradually, on repeated questioning, he admitted his estimated intake to be 12 to 16 oz. (340 to 454 gm.) weekly. His wife told us that he took considerably larger amounts at times and that physicians repeatedly advised him to discontinue the medication; however, he seemed unable to do so. He stated that he had taken bromo-seltzer® for "at least 10 years," because it gave him relief from headaches, nervousness, and abdominal pain.

On Aug. 29, the blood bromide level was 19.0 mEq. per liter, and, by spectrophotometric examination, 16% of the hemoglobin was found to be present in an abnormal form, presumed to be methemoglobin. The total hemoglobin level was 13.5 gm. per 100 cc. (Sahli acid-hematin method), and the arterial oxygen saturation was 82% (Van Slyke method). A total of 100 mg. of methylene blue was administered intravenously on Aug. 30 and again on Aug. 31, with no reduction of cyanosis. The amount of abnormal hemoglobin found on spectrophotometric examination was unchanged on Sept. 1. Ascorbic acid, 1,000 mg. daily for five days, had no effect on the cyanosis or the level of abnormal hemoglobin. The abnormal pigment was then tested for its stability to cyanide, using the quantitative

method of Evelyn and Malloy.[5] The absorption peak was not affected by the addition of cyanide solution, indicating that the pigment was sulfhemoglobin. There was no detectable methemoglobin in a fresh sample of blood.

The patient was warned of the possible consequences of continued bromo-seltzer® ingestion. During his hospital stay of 12 days, he manifested marked nervousness and irritability, which were only partially controlled by barbiturates. He seemed anxious to leave the hospital, presumably to obtain more bromo-seltzer,® although he stated he would never take it again. He has since been seen several times at the clinic, with cyanosis, sulfhemoglobinemia, and high blood bromide levels, but he is unwilling or unable to discontinue taking bromo-seltzer.® Constipation was rarely present; the patient stated that he took cathartics on the average of once a month.

Comment.—As in case 1, the fact that the abnormal hemoglobin was sulfhemoglobin was not appreciated until the cyanide differentiation test was performed. The diagnosis was not even suspected for several years, although the patient was seen by a number of physicians and given extensive symptomatic therapy for numerous vague complaints that were probably the result of rather than the cause of his drug habit. This patient did not have a significant degree of constipation nor was it an outstanding finding in the majority of the patients in this series. Constipation has been assumed to be an important factor in sulfhemoglobinemia, leading to abnormal hydrogen sulfide absorption and thus providing a source of sulfur. Sulfhemoglobinemia has often been ascribed to this substance alone in so-called enterogenous cyanosis, even though attempts to produce sulfhemoglobin in vivo with hydrogen sulfide have been disappointing.[6] Judging from the histories of our patients, constipation is not an essential factor in sulfhemoglobinemia. The diagnosis of enterogenous cyanosis, if such an entity exists, requires the most careful exclusion of acetanilid (or other drug) ingestion.

CASE 3.—A 42-year-old white woman was brought to the Los Angeles County Hospital on July 24, 1951, by the police department; she was unable to give a history. Information was obtained from a friend to the effect that she had been acting peculiarly, had difficulty with her speech, and had seemed "groggy," for approximately two months. For about the same period of time, a purplish color of the lips had been noticeable. He stated that she had been taking large quantities of bromo-seltzer® for a period of several months. The landlady had called the police because of the patient's peculiar behavior.

At time of admission to the hospital, the patient was semistuporous, confused, and unkempt. The mucous membranes were deeply cyanotic, and the skin was a slate-grey color. The blood bromide level was 23.8 mEq. per liter. On July 26, spectrophotometric examination of the blood indicated the presence of 0.72 gm. per 100 cc. of sulfhemoglobin, no methemoglobin was detectable. The total hemoglobin was 14.4 gm. per 100 cc. (Sahli acid-hematin method). The blood bromide level gradually fell to 10.3 mEq. per liter on Aug. 8. By Aug. 2, the patient's mental state had markedly improved. She admitted taking one bottle "or more" of bromo-seltzer® daily for approximately two weeks before admission "to settle her nerves." She denied long-term ingestion of bromo-seltzer,® although the history obtained from the friend contradicted her statement. No reliable information regarding constipation was obtained. Cathartics were not prescribed during the 12 day hospital stay. At the time of discharge, on Aug. 6, the cyanosis and slate-grey skin color were still evident. She did not return for a follow-up examination.

Comment.—This patient's symptoms were undoubtedly caused by the high blood level of bromide and not by the relatively small amount of sulfhemoglobin present, which actually would interfere only mildly with oxygen transport. The diagnosis of bromide intoxication might not have been made without the history provided by the friend. In a patient with these symptoms, the finding of cyanosis due to sulfhemoglobinemia should suggest the possibility of bromide toxicity from bromo-seltzer.®

CASE 4.—A 43-year-old white woman was brought to the Los Angeles County Hospital on April 10, 1950. She was semistuporous and irrational. The only history obtainable was given by a friend, who indicated that she had been "sick" for four days, had been taking bromo-seltzer® (amount not determined) for years, and had been drinking recently. Her old hospital record revealed that at the time of a laparotomy for suspected ectopic pregnancy, in 1935, one of the surgeons had noted that "the blood was extremely dark and bluish in color, suggesting methemoglobinemia." She was seen in the hospital admitting room in 1943, complaining of abdominal pain and vomiting, and, at this time, she gave a history of taking bromo-seltzer® almost daily since the age of 19.

At the time of admission, she was febrile, deeply cyanotic, and tachypneic, and there were rales at the right lung base. The cyanosis did not improve when oxygen was administered. The blood bromide level was 26.4 mEq. per liter. When the blood was examined with the spectrophotometer, 20% of the hemoglobin was found to be in an abnormal form, presumably methemoglobin. (A cyanide test was not done.) A total of 50 cc. of 1% methylene blue was given intravenously after the above determination. Cyanosis was reported to have "slightly decreased" but was still pronounced the next day and until the time of death. Her condition grew worse in spite of penicillin therapy, and she died on April 13. No further spectrophotometric examinations of the blood were made. Bronchopneumonia in the right lung was found at autopsy.

Comment.—Although definite proof of sulfhemoglobinemia is lacking in this patient, the failure of the cyanosis to disappear when a large dose of methylene blue was administered and the long-standing habituation to bromo-seltzer® strongly suggest its presence. The possibility that pneumonia could have been responsible for the continued cyanosis after methylene blue was administered seems remote, since the pneumonia was not extensive, and oxygen was used continuously without benefit. There was no reliable information available regarding constipation.

CASE 5.—A 70-year-old white man was admitted to the Los Angeles County Hospital on Jan. 30, 1949, complaining of exertional dyspnea and precordial pain of six months' duration. He also had frequent headaches and had noticed a constant blueness of his lips for the same period of time. He had been constipated "all his life." The blood pressure was 210/100 mm. Hg, and the heart was slightly enlarged. The mucous membranes and nail beds were deeply cyanotic. There were no evidences of congestive failure. The electrocardiogram indicated left ventricular hypertrophy.

Cyanosis persisted in spite of oxygen inhalation and complete relief of dyspnea. Blood withdrawn for chemical analysis had a brownish tinge. A history was then obtained of taking five teaspoonfuls of bromo-seltzer® daily for approximately 18 months. The blood was examined spectrophotometrically on Feb. 4; 30% of the hemoglobin was found to be present as an abnormal form, presumed to be methemoglobin. A cyanide test was not done. At the time of discharge, on Feb. 6, the blood bromide level had fallen to 7.6 mEq. per liter, and the cyanosis had decreased only slightly. Cathartics were prescribed four times during the hospital stay of 11 days.

---

6. Meyer, E.: Ueber das Verhalten des Nitrobenzols und einiger anderer aromatischer Nitrökörper im Organismus, Hoppe Seyler's Ztschr. f. physiol. Chem. **46**: 497, 1905. Harrop and Waterfield.[2]

Comment.—Again, proof of sulfhemoglobinemia is lacking; however, the fact that the abnormal hemoglobin was present five days after admission is strong evidence that it was sulfhemoglobin. Methemoglobin would have been reduced to hemoglobin in this period of time, unless there had been continued ingestion of bromo-seltzer,® which was fairly well ruled out by the falling blood bromide level. The failure of the cyanosis to improve with oxygen inhalation should lead to examination of the blood for the brownish blue color of methemoglobin or sulfhemoglobin, which does not redden with oxygenation.

Case 6.—A 77-year-old white woman was first seen at the Los Angeles County Hospital in June, 1947, with complaints of insomnia and headache and with poorly described abdominal pain. The liver and spleen were both palpable. The hemoglobin was 8.0 gm. per 100 cc. (Sahli acid-hematin method), and the red blood cell count was 2,400,000 per cubic millimeter. No cause was found for the hepatosplenomegaly and anemia. The patient was seen again in January, 1948, with similar vague complaints and the same findings. Moderate cyanosis of the skin and lips was noted but was not explained.

On the patient's third entry, in 1948, hepatosplenomegaly and anemia were still present. The hemoglobin was 10.0 gm. per 100 cc., the red blood cell count 2,650,000 per cubic millimeter, and the mean corpuscular hemoglobin 39 micromicrograms. There was diminished vibration sense in the lower extremities and an absence of free gastric acid after histamine injection. Examination of the bone marrow revealed hyperactive erythropoiesis without megaloblastosis. Pernicious anemia was suspected, but there was no appreciable reticulocyte response to liver extract.

On the fourth entry, in December, 1948, the findings were unchanged. Cyanosis was again noted, and spectrophotometric examination of the blood indicated that 25% of the hemoglobin was in an abnormal form, presumed to be methemoglobin. (The cyanide test was not done.) Drug ingestion was denied. She stated that her skin had turned blue at times over a period of many years. Congenital methemoglobinemia was considered, but ascorbic acid, 500 mg. daily by mouth for seven days, failed to change the level of abnormal hemoglobin.

In November, 1950, the patient was again admitted to the hospital with considerable cyanosis. When the blood was examined spectrophotometrically, 15% of the hemoglobin was found to be in an abnormal form. The addition of cyanide did not affect the pigment, indicating that it was sulfhemoglobin. The level of sulfhemoglobin did not change over a 15 day period of hospitalization. Conversation with relatives disclosed that the patient habitually took "Dr. Miles anti-pain pills" (2.0 grains [0.13 gm.] of acetanilid, tincture of capsicum, and caffeine [unspecified amount] in each tablet), often as many as 30 a day. When confronted with this evidence, the patient admitted (reluctantly at first) ingestion of this medication over a period of 50 years, stating that it "settled her nerves and relieved abdominal pain." She would not admit taking the pills in the amounts described by her relatives, claiming that four or five a day was her maximum intake. There was no evidence of withdrawal symptoms during any of the time she spent in the hospital. Tests of hepatic function, including serum albumin and globulin, sulfobromophthalein (bromsulphthalein®) retention, prothrombin time, thymol turbidity, and cephalin-cholesterol flocculation, were within normal limits. The patient complained of mild, chronic constipation, necessitating the use of a cathartic once or twice a week over a period of several years.

COMMENT

In most of the cases, the history of drug habituation was not obtained from the patient, illustrating the importance of using accessory sources of information such as the friends or relatives. Whether chronic acetanilid use represents habituation or true addiction has not been settled.[1a] No definite withdrawal symptoms were noted in any of the patients in this series, suggesting that psychic dependence was present rather than true addiction. Acetanilid appears to be the substance responsible for the many cases reported in the older literature of habitual use of various headache remedies, including bromo-seltzer.® The fact that bromo-seltzer® is easily obtainable is probably the reason for the high percentage of habitual users of this compound found in our series. Acetanilid is undoubtedly also the substance responsible for sulfhemoglobin production in our patients. We have never seen sulfhemoglobinemia in sodium bromide or triple bromide intoxication.

Judging from the numerous reports in the older literature,[7] anemia frequently occurs in patients with chronic acetanilid poisoning. The pathogenesis of anemia is unknown. It is often said to be macrocytic, on the basis of the color index or mean corpuscular hemoglobin. Gross suggests that this may be caused by falsely high hemoglobin estimations in the colorimetric methods because of interference by the color of sulfhemoglobin.[8] Anemia, supposedly macrocytic, was present in the patient in case 6; it was not seen in any of the other patients in the series. Hepatosplenomegaly is occasionally mentioned in reports of chronic acetanilid poisoning.[9] The pathogenesis is obscure, and the findings in the few patients who came to necropsy were nonspecific. Enlargement of the liver and spleen was noted in only one patient in this group. The degree of enlargement was not marked; it did not progress over a period of years; and there was no laboratory evidence of impaired liver function.

SUMMARY

The case histories of six patients seen over a two year period are discussed, illustrating the following points. Acetanilid habituation still occurs. It will seldom be discovered unless sources of information other than the patient's history are employed. Habitual usage appears to result from psychic dependence rather than true addiction. Bromo-seltzer® is the medication usually involved. The bromide may produce toxic effects, but it does not appear to be responsible for the habituation or the sulfhemoglobin formation.

Sulfhemoglobinemia rather than methemoglobinemia is a common result of chronic acetanilid use and probably accounts for the majority of cases of cyanosis reported following the ingestion of acetanilid containing compounds. Some unknown endogenous source of sulfur must be assumed to be present. It may be hydrogen sulfide, although constipation does not appear to be necessary for sulfhemoglobin production. Anemia and hepatosplenomegaly, both of unknown cause, may occur with chronic acetanilid poisoning.

Since this article was prepared for publication, a large number of cases of sulfhemoglobinemia, collected over an 11 year period, have been described by Brandenburg and Smith.[10] Most of their patients took bromo-seltzer.®

CLINICAL NOTES

ADRENAL ATROPHY AND IRREVERSIBLE SHOCK ASSOCIATED WITH CORTISONE THERAPY

Charles G. Fraser, M.D.
Fred S. Preuss, M.D.
and
Walter D. Bigford, M.D., Tucson, Ariz.

Recent clinical observations and animal experiments[1] have shown that prolonged administration of cortisone produces adrenal atrophy. According to the adaptation syndrome of Selye,[2] adrenal atrophy in turn may lessen the body's ability to withstand trauma and stress. One might suspect that patients receiving cortisone would not normally withstand major surgery; yet every day patients are successfully undergoing surgery while regularly taking cortisone in both the preoperative and postoperative periods.

We wish to present the record of a patient who, while receiving a prolonged course of cortisone therapy, underwent a major operation, cup arthroplasty of the hip, and died of immediate postoperative shock, in spite of normally adequate, aggressive antishock therapy. Postmortem examination revealed marked bilateral adrenal atrophy and other conditions consistent with shock.

REPORT OF A CASE

A 34-year-old man had had rheumatoid arthritis for a period of seven years. Almost every joint of his body was involved, particularly the hips, where there was a marked flexion contracture. The patient had been receiving cortisone for eight months. He first received 1,200 mg. of cortisone over a period of 10 days and then 100 mg. three times weekly. For two months prior to the present examination the patient had been taking 25 mg. of cortisone twice a day. Because of the pain in the right hip and flexion deformity, a cup arthroplasty in the right hip was advised.

Past History.—The patient had the usual childhood diseases, including smallpox, and had hay fever. Several episodes of mild skin petechiae were diagnosed as allergic purpura; the latest occurred after his use of cortisone. Bleeding, clotting, and prothrombin times were normal. The platelet count was normal.

Physical Findings.—Physical examination revealed a chronically ill-appearing, deformed man of 34 years, who was able to walk about in a stooped position with the use of crutches. He did not appear to be in acute pain. There was pronounced evidence of generalized rheumatoid arthritis. The heart and lungs were normal.

Laboratory Data.—X-ray studies revealed an essentially normal chest. The heart measured nearly 50% of the transverse diameter of the chest and was not enlarged in any one region. The red blood cell count was 4,220,000 and hemoglobin 13 gm. per 100 cc. Urinalysis disclosed no abnormalities. Serologic studies revealed nothing essentially abnormal. The white cell count was 11,000, with 72% neutrophils, 19% lymphocytes, 8% monocytes, 1 basophil, and no eosinophils.

Course in the Hospital.—The patient received cortisone up to the time of admission and two days later was taken to the operating room. Spinal anesthesia was employed, with tetracaine (pontocaine®) hydrochloride supplemented with thiopental sodium. The blood pressure at the beginning of the operation was 140/80 and the pulse rate 72. A routine cup arthroplasty of the right hip was performed. During the course of surgery the patient received one blood transfusion. His blood pressure did not fall below 110/80 during the whole procedure. After the first unit of blood was given, the second was begun. After the patient received 50 cc. of the second transfusion some muscular twitchings were noted, so that transfusion was discontinued to guard against a transfusion reaction. During the course of the surgery the patient never showed any real need for further supportive therapy. His blood pressure never went below 110/80 and his pulse rate never higher than 80. The operation extended over a period of an hour and one-half. Almost immediately after being transferred from the operating table to the bed the patient began to show some fall in blood pressure. The first postoperative blood pressure reading was 86/60, so that transfusion of another unit of blood was begun. In spite of rapid administration of 500 cc. of blood, the blood pressure continued to decline. A total of 250 cc. of plasma was given without appreciable change. It was felt at this time that there was something peculiar about this patient's reaction, because his estimated blood loss at surgery was not over 500 cc. and he had been given more than adequate replacement, but the blood pressure continued to decline. Five cubic centimeters of adrenal cortical extract was given on two occasions without benefit, and 500 cc. of plasma was given rapidly. In spite of this therapy, the blood pressure declined to about 40 systolic and the pulse became almost imperceptible. Five minims (0.3 cc.) of epinephrine was given intravenously without effect. Epinephrine was then given intracardially without effect.

[2] Selye, H.: The Physiology and Pathology of Exposure to Stress: A Treatise Based on the Concepts of the General-Adaptation-Syndrome and the Diseases of Adaptation, Montreal, Acta, Inc., 1950.

Instead of showing the usual signs of vasomotor collapse and shock, the patient appeared somewhat flushed, his respirations were labored, and he appeared to have air hunger. His axillary temperature rose to 102 F. The patient lost consciousness and died three hours after surgery.

Autopsy Findings.—An autopsy was performed 21 hours after death. There was evidence of marked generalized rheumatoid arthritis. The operative area revealed a moderate amount of hemorrhage, which did not exceed that usually associated with this type of operation. There were multiple small parenchymatous hemorrhages in the lungs and a small subendocardial hematoma in the left ventricular aspect of the interventricular septum. All abdominal viscera were severely congested. The most striking observation was pronounced atrophy of both adrenals (see the accompanying figure).

Microscopic Observations.—Microscopic examination of the tissue confirmed the gross findings. The three layers of the adrenal cortex were still identifiable, but each was markedly reduced in width. The cortical cells revealed no appreciable changes. The medulla was likewise atrophic. There were also a few petechiae in the brain parenchyma. The kidneys showed no evidence of a transfusion reaction. Negative sudan IV stains of brain, lungs, and kidneys ruled out fat embolism.

COMMENT

This case is reported to add a note of warning in the immediate preoperative use of cortisone. Experience alone will tell how often this unfortunate outcome will be repeated. If so, appropriate preventive measures will be necessary. They may consist of a period of rest from cortisone therapy, or a period of adrenal stimulation with the use of corticotropin (ACTH), or possibly even the use of larger doses of cortisone through the surgical period.

SUMMARY

A patient who underwent major surgery after receiving cortisone for a period of eight months died of immediate postoperative shock, in spite of normally adequate therapy. Postmortem examination showed marked bilateral adrenal atrophy, suggesting adrenal insufficiency. Judicious use of cortisone in patients about to undergo surgery is cautioned, to prevent adrenal insufficiency.

PERITONEAL CARCINOMATOSIS FORTY-ONE YEARS AFTER RADICAL MASTECTOMY

James C. Doyle, M.D., Beverly Hills, Calif.
and
George J. Hummer, M.D., Santa Monica, Calif.

The case reported is that of a woman in whom a radical mastectomy had been done at the age of 34 and who died of generalized peritoneal carcinomatosis at the age of 75. The carcinoma of the peritoneum was histologically typical of grade 2+ adenocarcinoma of the breast, while other primary carcinomas were not found. Four months prior to death the patient's only complaints were those related to procidentia, which possibly was due to the presence of ascitic fluid secondary to the carcinomatosis.

REPORT OF CASE

A white widow aged 75 was first seen Aug. 8, 1947. Her complaints were that she had "a growth" in the uterus, a feeling of "weight in the pelvis," urinary symptoms of frequency, nocturia, and dysuria, and protrusion of a mass from the vagina. The protrusion had been noted for years, and she had found it frequently necessary "to push the mass up" in order to urinate.

The patient's mother had died of cancer and her father of pulmonary tuberculosis. She had had two pregnancies, but both had terminated in early miscarriage. The menses had ceased at the age of 50. Her left breast had been removed in 1906 at the age of 34. She was not certain of the reason, but thought she had had cancer. The patient said she weighed 130 lb. (59 kg.) and that her weight had not varied in years. Elimination was reported as satisfactory with the aid of bran. She stated she did not have any abdominal pain, indigestion, or heartburn and had not noted any abdominal swelling. Her appetite had been poor recently.

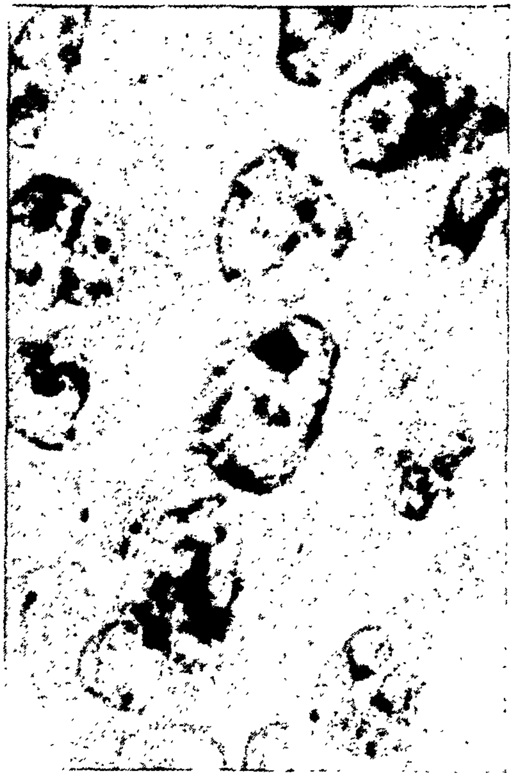

Fig. 1.—Malignant cells found in centrifuged ascitic fluid (tissue block: hematoxylin and eosin stain) (× 1,000).

When the patient was examined, her weight was 130½ lb. (59.23 kg.). Her temperature was 98.2 F (36.8 C), pulse rate 112, respirations 18, and blood pressure 140 systolic, 80 diastolic. The heart and lungs were within normal limits to auscultation and percussion, and the right breast was normal. The left breast and pectoral muscles had been removed radically. The abdomen was moderately distended and tympanitic, and a small umbilical hernia was noted with a slight tenderness in this area. The pelvic outlet was relaxed and the cervix was normal in appearance. The uterus was completely prolapsed and irregular in outline, and cystocele and rectocele, both grade 3, were present. The urine contained an occasional pus cell and one to two red blood cells per high power field. The hemoglobin was 13.6 gm., 88% (Wintrobe). The erythrocyte count was 4,500,000, the color index 0.97, and the leukocyte count 8,000.

On Aug. 12 the patient was hospitalized. A flat film of the abdomen demonstrated the presence of fluid. A vaginal hysterectomy, followed by anterior and posterior colporrhaphy with insertion of Kelly stitches, was done Aug. 14. When the peritoneum was opened, about 2,000 cc. of blood-stained fluid escaped. The oviducts and ovaries seemed normal to palpation except for their adherence to the posterior surface of the broad

ligaments. Visualization was impossible. The uterus was enlarged and irregular in outline because of the presence of fibroids. The pelvic peritoneum was studded by scattered, discrete implants, each approximately 2 to 3 mm. in diameter, but it was not possible to remove one for biopsy. Whole blood, 500 cc., was given during surgery. The examination of the tissues removed at surgery indicated chronic cervicitis and uterine leiomyomas, although there was no evidence, either gross or histological, of malignant change.

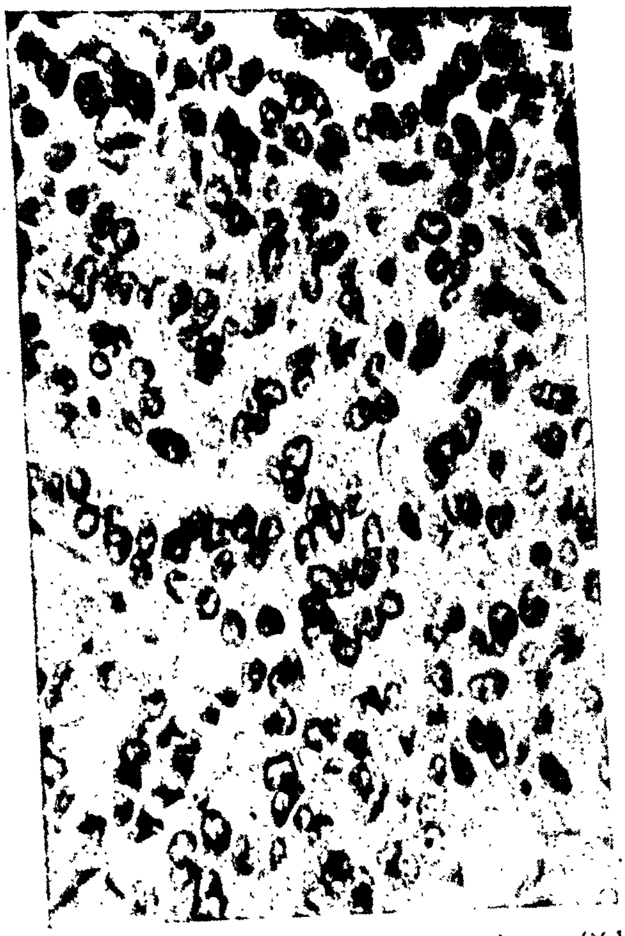

Fig. 2.—Adenocarcinoma pattern metastatic to peritoneum (× 160).

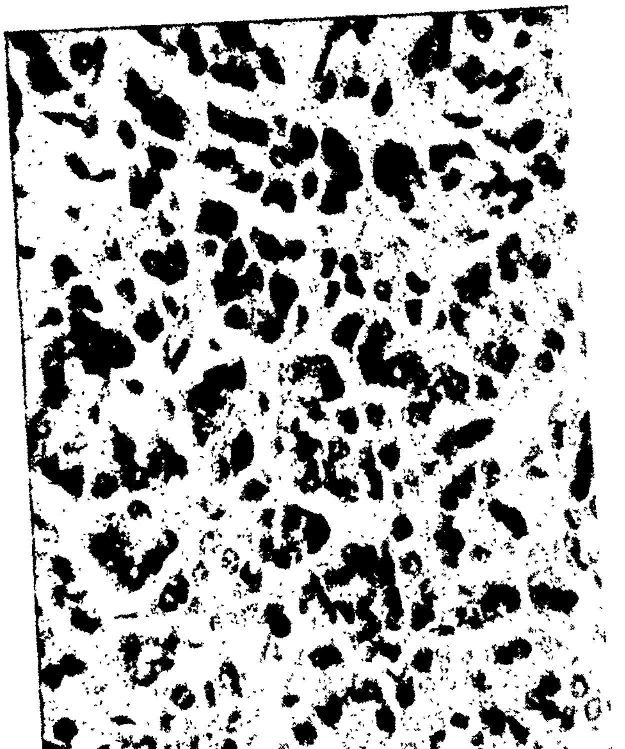

Fig. 3.—Note gland reduplication pattern of adenocarcinoma metastatic to peritoneum similar to mammary carcinoma (× 500).

The postoperative course was complicated the first few days by right-sided bronchopneumonia, possibly on the basis of a pulmonary infarct of the right lung. The patient left the hospital Aug. 30, the 15th postoperative day. During the next three months the patient had recurring episodes of ascites and paracentesis was required three times. The histological examination of centrifuged ascitic fluid on Oct. 7 indicated peritoneal adenocarcinomatosis (fig. 1). The patient lost considerable weight and complained of anorexia, nausea, and progressive weakness. She was readmitted to the hospital Nov. 23 and died Dec. 9. During this period of hospitalization, treatment was palliative.

The postmortem examination revealed generalized peritoneal carcinomatosis. The omentum had become a neoplastic mass, and the entire peritoneum, from the diaphragm to and including the pelvic peritoneum, was studded with dense collections of small and large neoplastic nodules. The ovaries had undergone senile atrophy and were rather easily separated from the small neoplastic masses of tissue studding their serosal surfaces. Neither ovary was involved with primary neoplasia. The esophagus, the thyroid, the lungs, the entire gastrointestinal tract from the cardiac end of the stomach to the anus, the pancreatic parenchyma, the kidneys, the adrenal glands, the urinary tract, and the bladder were carefully inspected for evidence of metastasis of neoplasm or of primary neoplasm. None was found. The remaining breast was carefully examined by multiple, closely spaced incisions of the parenchyma, but no neoplasia was noted. The carcinoma of the peritoneum was typical of a grade 2+ adenocarcinoma of the breast, and there was fairly good reduplication of breast acinar tissue in this peritoneal carcinoma (fig. 2 and 3). Other primary carcinomas were not found.

COMMENT

Unfortunately it has not been possible to trace the nature of the original tumor of the breast removed from this patient in 1906. The histological evidence points to adenocarcinoma of the breast as the primary neoplasm in this case. The clinical history suggests that ascites secondary to the peritoneal carcinomatosis had been sufficiently extensive to cause, in whole or in part, the uterine prolapse noted by the patient for a number of years. Four months before her death, however, she denied abdominal pain or swelling, although stating she was extremely uncomfortable. All physical observations at that time were within normal limits, with the exception of the pelvic and urinary symptoms incident to the uterine procidentia. Her weight had been unaltered for years, and her appetite had been good until about five months prior to her death.

A search of the available literature reveals only one other case in which so long a time elapsed between discovery of the original lesion and the appearance of metastases. In that case, reported by Davidson and Ratcliffe,[1] a bilateral mastectomy had been done in 1902. The diagnosis of cancer had been confirmed microscopically, although the original record and slides were not available. Early in 1942, and again in 1943, small masses in the region of the left sternomastoid muscle were removed. The patient died in 1945. At necropsy all evidence of metastases was limited to the thoracic cavity. The tissues from the neck and the thorax had considerable cytological resemblance to both the basal cell carcinoma of the skin and the intraductal carcinoma of the breast.

---

[1] Davidson, W. R., and Ratcliffe, A. W.: Metastatic Carcinoma Afte Forty Years, J. Indiana M. A. 39: 165 (April) 1946.

The survival of a patient 31 years after removal of a breast for cancer was reported by Steward in 1925.[2] The patient died within a few months after the recurrence of the lesion was noted. This consisted of three small, hard nodules beneath the skin of the chest near the mastectomy scar. There was suggestive evidence of a mediastinal growth. A necropsy is not mentioned, nor is there any indication that a microscopic examination was made of any of the suspicious lesions, or of the tissue removed at mastectomy.

Kretzler's [3] patient had a mastectomy for cancer in 1902. A recurrence was first noticed in 1916, yet death from generalized metastases did not occur until 1926, 24 years after the original mastectomy. Clinically, in 1924, the metastases seemed to involve the other breast, the axilla, downward toward the navel, and up along the right side of the neck. The lung also had evidence of marked involvement. Necropsy was done, but the extent of the metastases is not given in the report. Tissue obtained at necropsy was classified histologically as adenocarcinoma of the breast, but the site of this tissue is not given. Chilko and Quastler [4] reviewed the literature on metastasis in cancer of the breast in 1942. The longest elapsed time between mastectomy and the recurrence of metastasis cited by them was 16 years.

Metastasis confined to the peritoneum below the diaphragm is another feature reported infrequently. Willis,[5] in his study of the spread of tumors, published in 1934, considered that long-delayed metastatic recurrence is by no means infrequent, especially in mammary carcinoma. In none of the data included in his study, however, does he cite a case of metastasis confined to the peritoneum.

Josephy [6] records a 23 year survival after mastectomy for cancer. The operation was done in 1927. Two years later there was metastasis to the axilla, and 19 years after, metastasis to the opposite axilla (the opposite breast not being affected). In 1950, 23 years after the original mastectomy, the patient died. The abdominal cavity contained about 4 liters of fluid. There were metastases to the omentum, the mesentery, and the pelvic and diaphragmatic peritoneum and also to the leptomeninges and the subarachnoid space. The lungs, stomach, intestines, liver, gallbladder, spleen, pancreas, suprarenal glands, ovaries, uterus, urinary bladder, and brain were searched for evidence of primary tumor, but none was found. Microscopic examination revealed a diffuse carcinomatous invasion by way of the lymphatics, with little tendency to form large nodes or masses. The cells were identical with those in the axillary lymph nodes removed in 1948.

Woolsey [7] reported a case in which the breast had been removed for cancer in 1905. Sixteen years later the patient was alive and well. In the intervening period a pelvic operation and a cholecystectomy had been done. At one time she complained of abdominal pain, gas, vomiting, loss of appetite, and headache; but a roentgenologic examination was normal, and her symptoms disappeared, so that suspicion of an abdominal metastasis was not confirmed.

SUMMARY

A case of carcinomatosis confined to the peritoneum 41 years after radical mastectomy is reported. A brief search of the literature indicates that cases in which there is either the type of metastases or the long duration recorded here are infrequently reported.

PULMONARY RESECTION FOR METASTASIS FROM CARCINOMA OF THE LUNG

REPORT OF A CASE

Adrian Lambert, M.D., New York

In a recent summary of the literature concerning pulmonary resection for metastatic malignant lesions, Seiler, Clagett, and McDonald [1] found 68 cases recorded up to 1950. In the 63 cases in which the type of the primary tumor was mentioned, the most frequently occurring types were carcinoma of the large bowel (11 cases), fibrosarcoma (9 cases), hypernephroma (8 cases), and carcinoma of the ovary (5 cases). In the entire series there were no cases reported of pulmonary resection for metastasis from the lung as the primary site of the tumor. The fact that this has not been done is not because of the rarity of this type of extension. Ochsner and DeBakey [2]

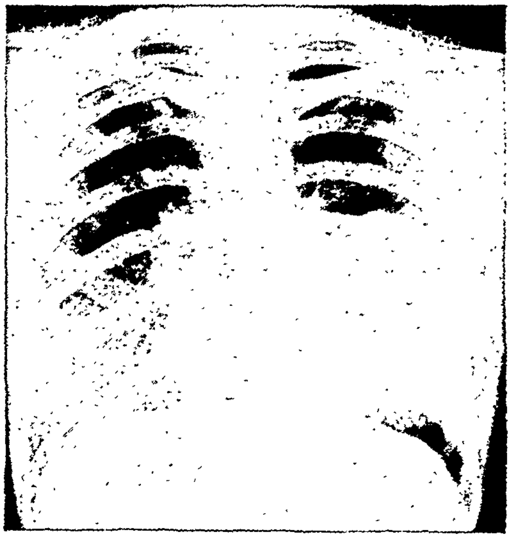

Fig. 1.—Roentgenogram (posteroanterior view) taken one month before first lobectomy was done, showing tumor in the upper lobe of the left lung.

Several illustrations have been omitted from THE JOURNAL and will appear in the author's reprints.

REPORT OF A CASE

A 28-year-old woman was observed during routine roentgeno-graphic examination to have a large, circular, well-circumscribed shadow in the left upper lung lobe that extended down anterior-ly almost to the diaphragm (fig. 1 and 2). The only symptoms

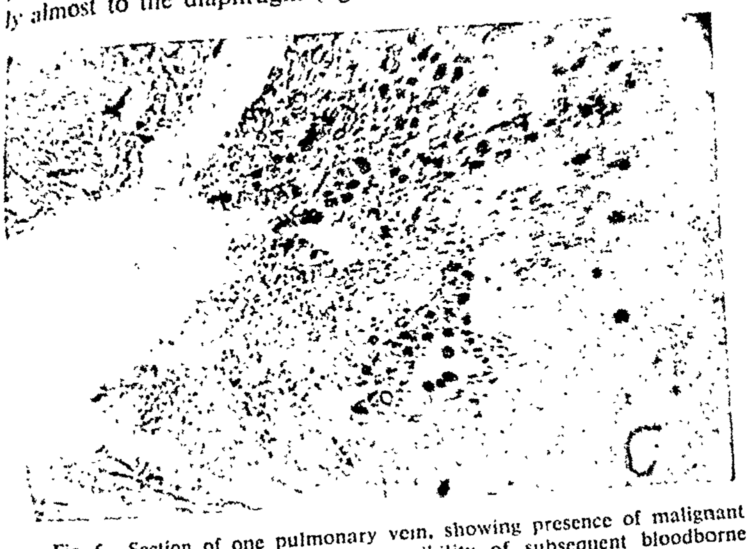

Fig. 6.—Section of one pulmonary vein, showing presence of malignant cells in the lumen, suggesting the possibility of subsequent bloodborne metastasis.

she had were fatigue and a slight cough for three weeks before her admission to Roosevelt Hospital on Jan. 25, 1946. On physical examination she appeared to be normal, except for a small amount of dullness on the anterior axillary line on the left side of her chest. Results of laboratory tests were as follows: hemoglobin, 91%; white blood cell count, 10,300 per cu. mm.,

metastases. ... nths later, a mass developed in her left
thigh, and it was excised as a possible metastatic lesion; it turned
out to be only fibrous tissue that was diagnosed pathologically
as a benign fibroma.

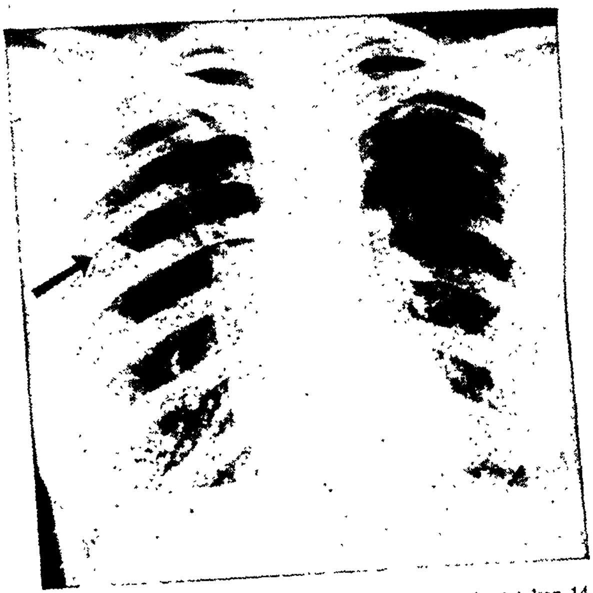

Fig. 7.—Roentgenogram (posteroanterior view) of chest taken 14 months after left upper lobectomy for primary tumor, showing (arrow) metastatic lesion, 1 cm. in diameter, in upper lobe of the right lung.

The patient remained free of symptoms until one year from her first operation, at which time she developed a slight non-productive cough. She felt well and had lost no weight. A roent-genogram made at this time showed a small, nodular, discrete shadow about one-half centimeter in diameter in the upper lobe of the right lung. It had the appearance of a metastatic nodule and in subsequent roentgenographic examination it was observed to have enlarged slightly (fig. 7 and 8). A diagnosis of metastatic carcinoma was made, and the patient was brought into Roosevelt Hospital for an exploratory operation 14½ months after her first lobectomy. At operation, a right upper lobectomy was done for a metastatic tumor in the upper lobe of the right lung (fig. 9), which on microscopic examination was seen to consist of the same type of tissue as the primary growth. The glands were atypical, columnar in type, and arranged in multiple layers. The nuclei were fairly uniform in size and rich in chromatin, with about one mitotic figure per high power field (fig. 10). The regional lymph nodes removed before lobectomy showed n malignancy.

Following the operation, the patient had an uneventful re
covery and was allowed to go home on the 14th postoperativ
day. Since that time she has been well, and, except for an oc
casional slight cough due to a cold, she has been free of symp
toms. At no time has she been conscious of getting out o
breath. A recent roentgenogram showed no evidence of furth
metastasis (fig. 11). It is now six years and five months sin
her first operation and five years and two months since h
second.

COMMENT

Isolated cases [3] of removal of solitary metastatic nodules in the lung have been reported in the literature since the first case was reported by Divis in 1927.[4] It was not until Churchill [5] reported a nine year follow-up after removal of a single metastatic lesion that it became evident that prognosis was not rendered hopeless by the presence of pulmonary metastatic carcinoma. Since that time, Alexander,[6] Blades,[7] Clagett,[1] and others have added case reports to the literature, the opinion now being that removal of a solitary malignant metastatic lesion in the lung is indicated after adequate removal of the primary tumor in patients in which there is no evidence of further metastasis. In the present patient the primary tumor was removed before any symptoms had occurred, and yet it had already undergone early microscopic metastasis via the blood stream, as so frequently occurs in adenocarcinoma.

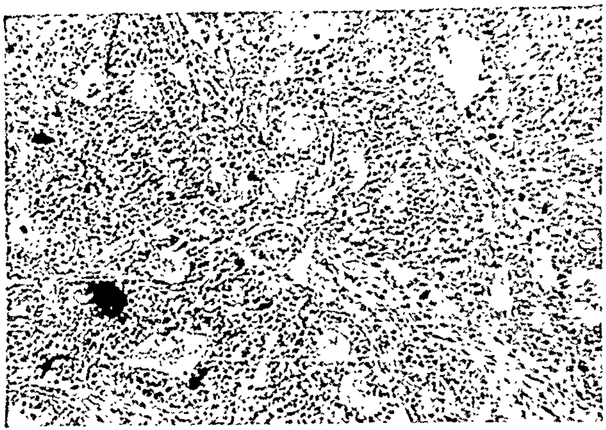

Fig. 10.—Microscopic section of secondary tumor, showing identical type of glandular epithelium as present 15 months earlier in primary tumor.

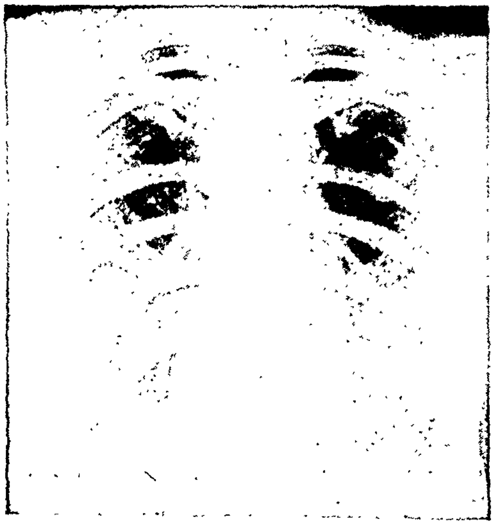

Fig. 11.—Roentgenogram (posteroanterior view) taken five years and three months after the original lobectomy and four years and one month after removal of the metastatic lesion, showing no further evidence of recurrence of carcinoma.

As early as 1903, Schmidt [8] noted how frequently cancer cells occur within the pulmonary vessels in primary carcinoma of the lung. In 1931, Fried [9] concluded that this is the essential manner of dissemination in bronchogenic carcinoma, because the condition is invariably present. This was corroborated by Boyd,[10] who noted blood vessel invasion in all patients in whom distal metastasis had occurred. Later, Koletsky [11] concluded that the adenocarcinoma type was more likely to metastasize by way of the blood stream and produce widely distributed metastatic lesions than the other types. In 1941, Gebauer [12] corroborated this conclusion in a series of 158 cases.

It is interesting to speculate on the method of extension. In the present case, the cancer cells may have travelled from the pulmonary vein through the left auricle and ventricle to the right lung by way of the bronchial artery, or they may have reached the lung by way of the pulmonary artery after traversing the general circulation. A third possible route for hematogenous metastasis is from the left pulmonary vein through the left auricle to the right pulmonary vein and into the other lung. This would depend on a tidal type of flow in the pulmonary vein, which might occur in the presence of an open chest. The route of spread can not be proved, but it is of significance in the evaluation of early metastasis.

In the present case, absence of lymph node involvement in the several glands removed from the mediastinum and the complete gross containment of the tumor in the upper lobe at the first operation were considered indications for lobectomy rather than pneumonectomy. This decision enabled further resection of the lung for metastatic involvement of the other side without making the patient a respiratory cripple. It is felt, therefore, that lobectomy is the operative method of choice in certain selected cases, such as this one, in which the patient's tumor was localized and was of the type that metastasizes first through the blood stream.

SUMMARY

A case of the removal by lobectomy of an adenocarcinoma of the upper lobe of the left lung and of a solitary metastasis to the right lung occurring 14½ months later is reported. The patient is still living and well six years and five months after the first lobectomy and five years and two months after the second lobectomy for the metastatic lesion.

ADENOMATOUS APPENDICULAR POLYPS

P. C. Martineau, M.D.
G. J. Coloviras, M.D.
and
S. M. Wallace, M.D., Detroit

Adenomatous appendicular polyps are rare. White and Ellis[1] collected a total of 21 cases from the literature in 1945 and added a single case of their own. In 1948 Brewer and Marcus[2] described a patient in whom the polyp had caused an intussusception of the appendix. They were able to gather four other similar cases from older literature, prior to 1923. Numerous workers[3] have suggested that these polyps are precancerous lesions with potentialities similar to those of adenomatous polyps of the colon. Uihlein and McDonald[3c] reported cases studied photomicrographically showing "an adenomatous polyp" containing "regions of malignancy characterized by larger deeper-staining nuclei." They prefer to call tumors with anaplastic areas of that type "papillary adenocarcinoma grade I." In another paper Woodruff and McDonald[4] described a role that adenocarcinoma grade 1 of the appendix may play in the formation of a mucocele and of pseudomyxoma peritonei. We wish to report a case of multiple adenomatous polyps of the appendix complicated by acute appendicitis. According to Collins' review of cases,[5] adenomatous polyps of the appendix are usually single but may be multiple. They are usually found in the age group between 6 and 40 years. The majority of polyps are small, measuring from about 0.5 to 3.0 cm. in length. The polyps are usually found in the middle third of the appendix. Over half of the reported cases were complicated by appendicitis. A few cases have been associated with moderate hemorrhage into the intestinal tract.

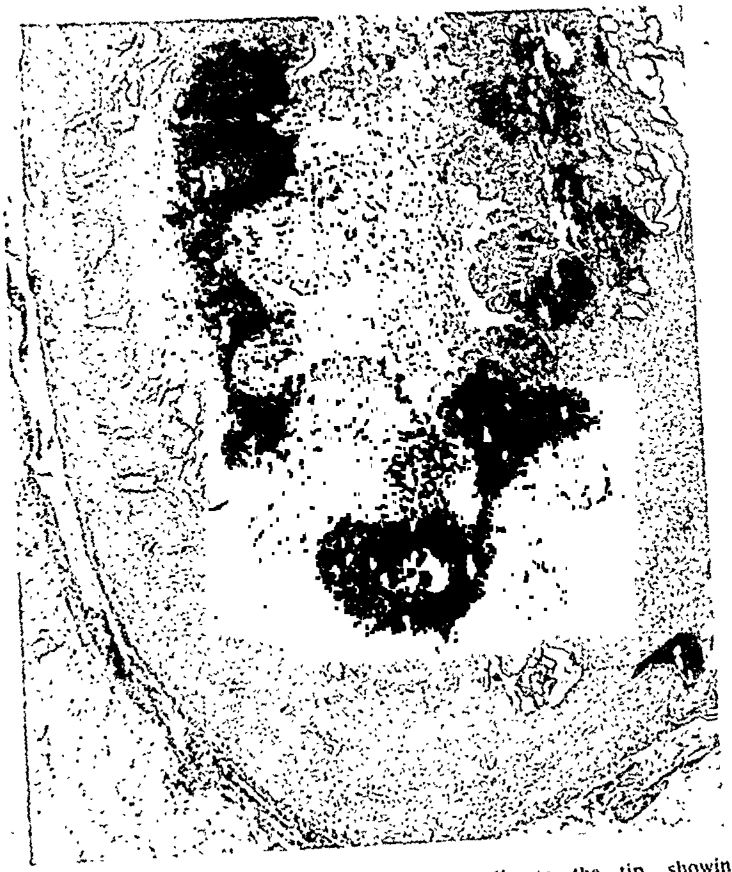

Fig. 1.—Longitudinal section of the appendix to the tip, showing multiple small microscopic polyps (hematoxylin and eosin, × 10).

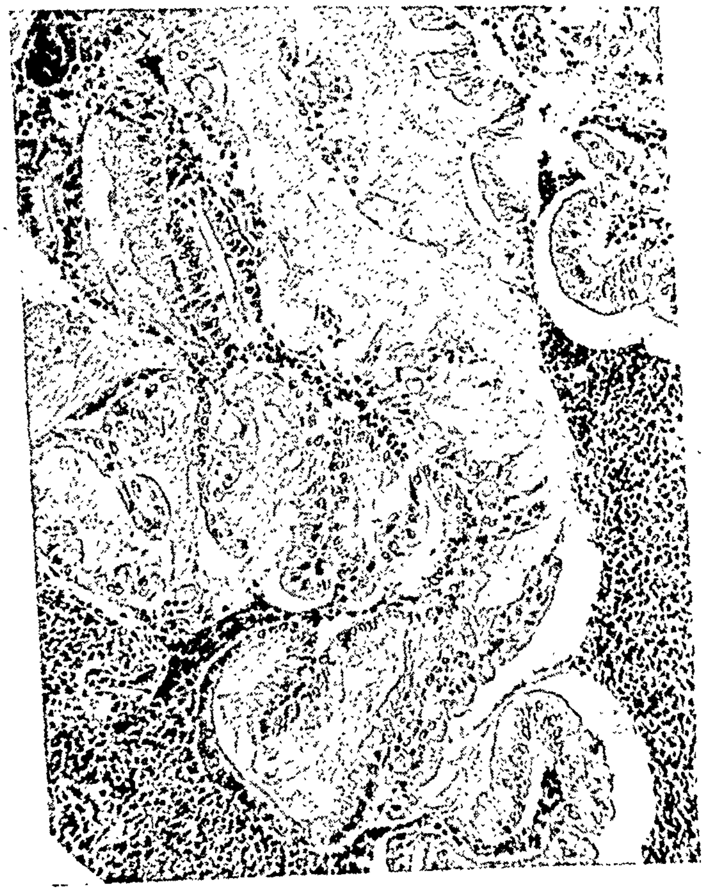

Fig. 2.—Photomicrograph of a small portion of the largest polyp, showing well-differentiated mucus-producing columnar cells and many polymorphonuclears (× 250).

REPORT OF A CASE

A 41-year-old white foundry foreman was admitted to Herman Kiefer Hospital on Sept. 17, 1951, with far-advanced tuberculosis and silicosis. While being treated with streptomycin, paraaminosalicylic acid, and bed rest for his tuberculosis, on Dec. 4, 1951, he suddenly experienced abdominal pain. The discomfort was generalized at first but became localized in the right lower abdominal quadrant within 24 hours. The pain was cramplike, and there was tenderness on palpation over the appendix. Some rebound tenderness was also noted in the right lower quadrant. The patient's appetite was unimpaired, and he had had three bowel movements since the onset of his abdominal pain. The patient had a temperature of 101 F and a pulse rate of 120. The leukocyte count was 15,400, with a differential count of 89% polymorphonuclear neutrophils, 6% lymphocytes, 3% monocytes, and 2% eosinophils.

There was no history of previous attacks similar to the present illness. An appendectomy was done on Dec. 5. The subserosal vessels were congested. There was a small amount of free fluid about the appendix. On culture this proved to be sterile. No masses were noted in the cecum or immediately adjacent ileum. The rest of the abdominal cavity was not explored. The patient's postoperative course was uneventful. At the time of writing the patient was continuing treatment for tuberculosis.

From the departments of pathology and surgery of Herman Kiefer Hospital and Wayne University College of Medicine.

Gross Description.—The appendix measured 6 by 1 cm. The serosal vessels were moderately injected, but no exudate was visible on the serosa. On cut section the appendiceal wall was seen to be thickened, white, and firm. The lumen was small and stellate. At a point near the middle of the appendix there was a small polypous mass projecting into the lumen. This mass measured about 8 mm. in its greatest dimension. Its surface was finely granular. Multiple smaller polypous masses projecting into the lumen were seen out toward the tip.

Microscopic Findings.—A cross section of the appendix through the polyp showed a papillomatous arrangement of tall columnar mucus-secreting cells. The cells were arranged in single row about a central fibrous stroma with a delicate, branching, fern-like structure. The nuclei of the cells were well oriented at the base of the cell. No bizarre hypochromatic nuclei were found, and no mitotic figures were seen. Numerous crypts were formed in the polyp. The appendiceal lumen also contained many polymorphonuclear neutrophils and necrotic debris. There was ulceration of the mucosa and widespread infiltration of the submucosa and subserosa with acutely inflammatory cells. No epithelial infiltrations of the appendiceal wall were found. The polyp did not completely occlude the lumen at any point. A longitudinal section of the distal 2 cm. of the appendix showed multiple small hyperplastic areas of redundant mucosa forming microscopic polyps with broad bases.

COMMENT

The structure of the polyp present in our case was similar to that shown in photomicrographs of many previously reported cases. We agree with those authors who believe that this tumor should be regarded as similar in malignant potentialities to adenomatous polyps of the colon. We also feel that obstruction of the lumen of the appendix was an important factor in inducing acute inflammation in this case.

LONGEVITY WITH COMPLETE ATRIOVENTRICULAR BLOCK

Julien E. Benjamin, M.D., Cincinnati

and

Paul D. White, M.D., Boston

Two case reports of patients known to have complete heart block for 35 years are presented for the purpose of adding to the literature further information on the important aspect of prognosis in this disease of the heart. Atrioventricular block has always been an important clinical problem in itself and also in indicating the existence of serious disease or toxic states. Occasionally, however, and possibly more often than is generally appreciated, etiological factors may influence strikingly the course of this disease.

REPORT OF CASES

Case 1.—Miss L. W., aged 57, a white registered nurse, was known to one of us (J. E. B.) for 35 years. In 1910, when she was hospitalized for a minor surgical procedure, it was noted that she had a "slow pulse." The patient's mother told her that when she was very young the family doctor had observed her unusually slow pulse rate. She had a remarkably healthy childhood and had engaged in all the games characteristic of her play group. Her development was in every way normal. She had had no serious illness at any time and no major operations. She entered nurses' training school (Cincinnati General Hospital) at the age of 19 and passed the entrance physical examination but again was informed of her slow heart rate. Her first electrocardiogram, a pioneer record in the Middle West, taken in 1916 when she was 23 years old, showed complete heart block (fig. 1). During the training period her schedule was strenuous, involving 12 hour shifts of day and night duties, alternating every 3 or 4 months. After graduating she was assigned, in a supervisory capacity, to medical wards, and her work was exacting and strenuous. She rarely lost time due to intercurrent minor illnesses. She continued in this role for 15 years. In the following years she either worked as a private duty nurse or did nursing in the outpatient dispensary. During the past five years she worked daily in one of the nurses' dormitories supervising several activities. Her health remained astoundingly well. It is noteworthy that at no time in the years she was under observation did she have any complaints referable to her heart or circulation. She was a very stable person.

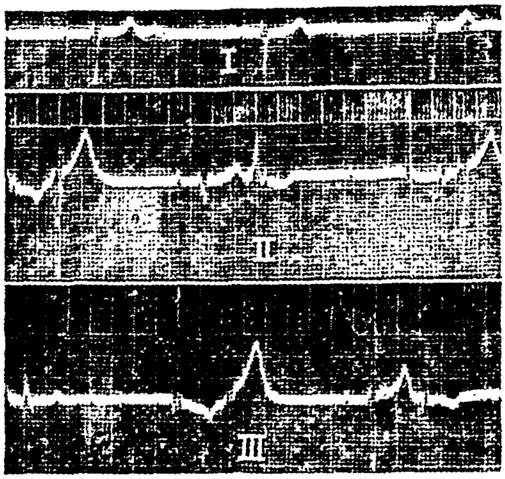

Fig. 1.—Electrocardiogram of patient L. W., taken in 1916, showing complete atrioventricular block, with atrial rate of 80 to 85 and ventricular rate of 40 beats per minute (except at the time of ventricular bigeminy).

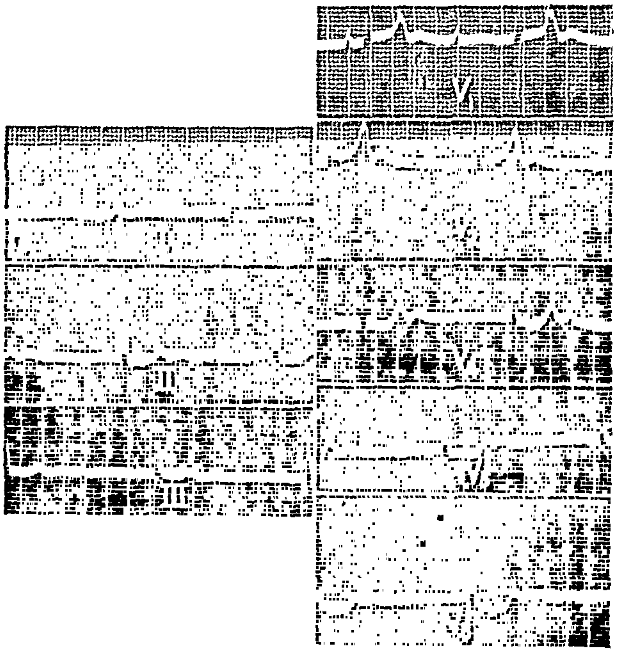

Fig. 2.—Electrocardiogram of patient L. W., taken Sept. 20, 1950, showing complete atrioventricular dissociation, with atrial rate of 60 and ventricular rate of 30 beats per minute. The atrial beats came at irregular intervals, whereas the ventricular beats came at regular intervals.

In February, 1948, the patient was examined because of a sense of exhaustion, residual from a recent upper respiratory tract infection, and it was noted that the pulse was irregular and

---

Dr. Jan Schwarz performed the autopsy reported in case 1 of this article.

rapid. An electrocardiogram later revealed unmistakable atrial flutter and high-grade atrioventricular block. The patient had no complaints referable to her heart. The atrial flutter subsided in a few days with digitalis and quinidine therapy and rest in bed. It is doubtful whether medication influenced this disturbance in rhythm. There was no recurrence, and her circulation was not disturbed by this episode. Evidence of atrioventricular block was again apparent and remained so. She continued her daily activities and worked eight hours each day with no discomfort.

In a recent physical examination, the patient was about 20 lb. (9.1 kg.) overweight, in good health, and of a genial nature. She had no physical complaints. The optic fundi showed grade 1 changes in the vessels and the peripheral vessels were soft; the veins showed no gross changes. A roentgenographic examination indicated the heart was generally somewhat enlarged. There were no abnormal pulsations. The neck vessels were essentially normal. The heart rate was 32 beats per minute at the apex, changing little on exercise, and there was no pulse deficit. The sounds were clear and sharp, with A_2 considerably louder than P_2. A grade 3 rough systolic murmur was heard over the entire precordium; it was louder at the apex, was not transmitted to the axilla, and was heard distinctly between the scapulas. The blood pressure was 180 mm. Hg systolic and 65 mm. Hg diastolic; this had varied only slightly in many years. Capillary pulsations were easily demonstrable. A third heart sound was frequently audible. In fluoroscopic examination, a sclerotic aortic valve was vaguely discernible and the dissociated rhythm of the chambers that could be observed occasionally was impressive. The lungs were normal. The circulation time (arm to tongue) was 32 seconds. The venous pressure was 21 mm. of water at the level of the right atrium. The vital capacity was 69% of normal. The last electrocardiogram made before the patient died is shown in figure 2 and is exactly as the record had been for many years, except for the electrocardiogram made in February, 1948. Abdominal, pelvic, and neurological examinations were unrevealing. The results of urinalysis and hematological tests were within normal ranges.

On May 10, 1951, the patient experienced a sudden attack of dyspnea (while at rest), which persisted in varying degrees up to the time of her death. There were no other signs of heart failure; however, the venous pressure was 280 mm. of water and the circulation time was 30 seconds (dehydrocholic acid [decholin®] method). The brachial arterial pressure was 140/60 mm. Hg. The cardiac rate was 40 beats per minute. An electrocardiogram revealed an atrial flutter, with 7 or 8 to 1 heart block, the ventricular rate varying from 40 to 50 beats per minute. The patient was given 24 grains (1.55 gm.) of quinidine sulfate during the ensuing 24 hours, with return of the previous complete heart block and disappearance of the flutter. On May 11, 1951, several hours after quinidine therapy was discontinued, the patient had a generalized convulsion, following which she became extremely dyspneic and cyanotic. During the seizure the pulse could not be felt, but a few moments after her return to consciousness the former slow rate returned and there was no notable change in her general condition (Adams-Stokes attack [?]). Five hours later, a syncopal attack occurred, which lasted long enough for an emergency electrocardiogram to be taken, revealing ventricular tachycardia, which vanished with the patient's return to consciousness. For the ensuing eight hours cyanosis and orthopnea persisted, although the patient was receiving oxygen by a nasal catheter. Diuretics produced no effect, although administered early in the illness. This was also true of other medicaments. The patient stopped breathing suddenly 36 hours after the onset of the final illness.

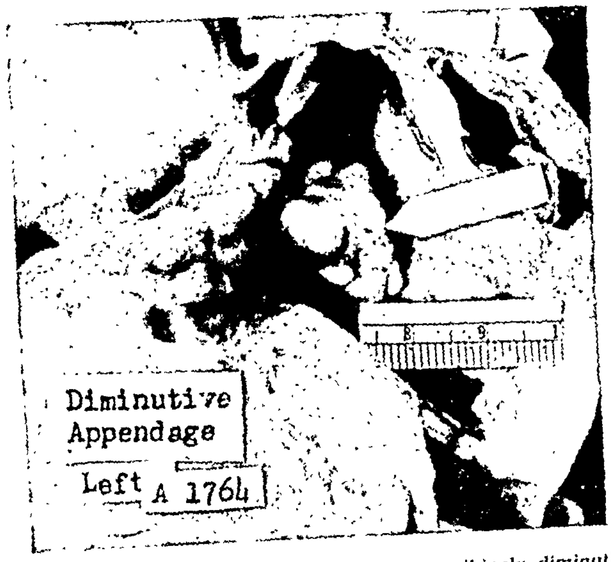

Fig. 3.—Heart of patient L. W., showing the strikingly diminutive size of the left atrial appendage (arrow), which is apparently a vestige. A developmental abnormality was also noted in the left circumflex coronary artery.

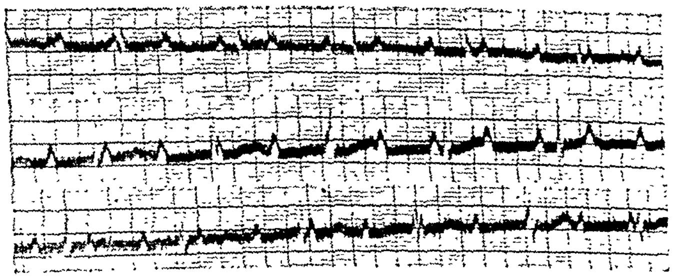

Fig. 4.—Electrocardiogram (reading from top to bottom, leads I, II, and III) of patient C. A., taken Nov. 13, 1916, showing complete atrioventricular dissociation, with otherwise normal complexes. The atrial rate is 120 and the ventricular rate 55 beats per minute. This record was taken while the patient was thyrotoxic.

Autopsy Report.—The conditions observed in the cardiovascular system, the only pertinent ones disclosed, are the only ones reported here.

On opening the chest, approximately 600 cc. of a clear straw-colored fluid was found within each pleural cavity. The pleural surfaces were smooth and glistening. The lungs were expanded and light blue in color. The pericardial sac was opened and was observed to contain approximately 25 cc. of a straw-colored fluid. The heart was enlarged. The first portion of the ascending aorta appeared slightly dilated (aneurysmal), and the wall was calcified. The diaphragm on the right rose to approximately the fifth rib and on the left to the fifth interspace. The heart weighed 590 gm. and had the following measurements:

Circumference of tricuspid ring	11.5 cm.
Circumference of pulmonic ring	6.5 cm.
Circumference of mitral ring	10 cm.
Circumference of aortic ring	6.5 cm.
Length of right ventricle	8 cm.
Length of left ventricle	7 cm.
Thickness of right ventricular wall	3 to 7 mm.
Thickness of left ventricular wall	9 to 15 mm.

The epicardial surface was smooth and glistening. A small amount of subepicardial fat was present over the coronary arteries. The heart was opened in the usual manner, and all valves appeared to be both anatomically and functionally competent. There was an increase in the amount of atheromatous material in the aortic cusp. The first portion of the aorta showed calcification of the wall and moderate dilatation. All chambers were dilated and hypertrophied. Examination of the left atrium revealed the presence of a yellow calcific material, measuring approximately 15 mm. in its greatest diameter, in an area that usually contains the remnants of the foramen ovale. No foramen ovale remnant was visible. Leading into a small left atrial appendage was a narrow orifice measuring approximately 8 mm. in diameter, which had subendocardial suffusion; no mural thrombi were noted. The walls and papillary muscles were strikingly hypertrophied. The chordae tendineae showed no remarkable changes. Examination of the coronary arteries revealed a slit-like opening for the ostium of the left coronary artery; an extremely small left circumflex artery was found. The right and left anterior descending coronary arteries were patent throughout and showed marked sclerosis of their walls. The myocardium was not sectioned because of further study to be made.

The wall of the aorta was thickened and had poor elasticity. There was dilatation of the first portion of the ascending aorta; the remainder, however, showed no aneurysmal dilatation. On opening the aorta, the intima was seen to be yellow in color.

Scattered atheromatous plaques were seen, many of which were calcified, and were most prominent in the abdominal aorta. No ulcerations or dissection was noted. The major branches were fully patent but sclerotic.

The gross pathological diagnosis was as follows:

1. Dilatation and hypertrophy of the heart (moderate).
2. Generalized arteriosclerosis (severe).
3. Ascending aortic aneurysm, arteriosclerotic in type.
4. Diminutive left atrial appendage (fig. 3).
5. Greatly enlarged right atrial appendage.
6. Vestige of left circumflex coronary artery.
7. 15 mm. area of calcification of interatrial septum, left atrial.
8. Congestive failure, lungs and liver.
9. Hydrothorax, bilateral.
10. Severe pulmonary edema, bilateral.

It should be noted that congenital abnormalities were present, namely, vestigial left atrial appendage and left circumflex coronary artery. The calcified plaque in the interatrial septum as well as the greatly enlarged right auricular appendage may also have been present at birth. The assumption that congenital heart block, mentioned in the body of this report, was the etiological factor could well be true. The task of sectioning the region of the bundle of His and its branches is to be undertaken.

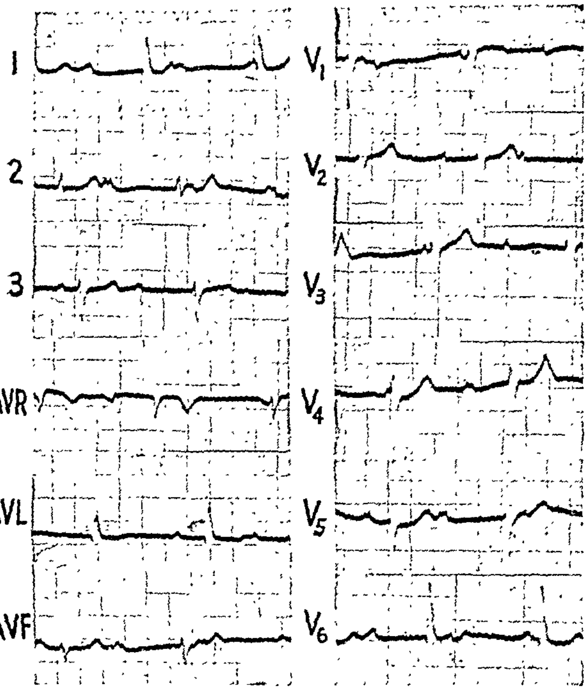

Fig. 5.—Electrocardiogram of patient C. A., taken Dec. 1, 1950, showing complete atrioventricular block, with an atrial rate of 80 to 85 and a ventricular rate of 55 to 60 beats per minute. Except for the atrioventricular block there is no gross abnormality shown in the electrocardiogram. The R waves in V_1, V_2, and V_3 are small but within the normal range.

Case 2.—Miss C. A., aged 58, a music teacher, has been known to one of us (P. D. W.) for 35 years. Her first electrocardiogram was made in November, 1916, at the age of 24. A slow pulse rate (40 beats per minute) had been noted by her family physician 12 years previously, incident to routine examination. She had had severe diphtheria at the age of 1½ years. She has been observed annually during the past 35 years and has continued to be in good health, except for exhaustion and other symptoms of neurocirculatory asthenia and functional disturbances of the peripheral circulation. Recently there have been occasional spells of bradycardia, with the heart rate ranging between 30 and 39 beats per minute.

The first electrocardiogram made in 1916 showed complete atrioventricular block with an atrial rate of 120 beats per minute and a ventricular rate of 55 (fig. 4). This record was made at the time she was taking thyroid in moderate dosage because of an erroneous diagnosis of myxedema. This diagnosis had been made hastily on the basis of the slow heart rate alone, since the heart rate did not change normally in response to exercise. The patient was thyrotoxic at that time. The electrocardiogram cleared up the mystery. There has been no change in the electrocardiogram since the first record, except for some slowing of both atrial and ventricular rates. When examined, the heart has always shown good sounds and forceful action, with a moderate (grade 3) systolic murmur over the entire precordium, loudest at the left of the mid and lower sternum. Fluoroscopic examination has shown slight enlargement of the heart that has not changed over the years.

On Dec. 1, 1950, on physical examination, the patient looked well. Her weight was 153 lb. (69.4 kg.). The pulse rate was regular at 54 beats per minute. The blood pressure was 175 mm. Hg systolic and 90 mm. Hg diastolic. The feet and ankles were thick but not edematous. The heart showed good sounds; there was a grade 2 precordial systolic murmur. Fluoroscopic examination showed a slightly enlarged heart, as before. The lungs were clear. In an orthodiagram the transverse diameter of the heart measured 11.3 cm. and the internal diameter of the thorax measured 20.8 cm. The shadow of the aorta was slightly dense. An electrocardiogram showed complete atrioventricular block, with an atrial rate of 85 and a ventricular rate of 55 beats per minute and normal T waves throughout the classical limb leads, the unipolar leads, and the six precordial leads (fig. 5).

In June, 1952, Miss C. A. was observed to be in excellent health, 35½ years after her complete heart block was first discovered.

COMMENT

Complete atrioventricular block is an easily recognized cardiac arrhythmia and one well known to clinicians; however, it is relatively rare, as was indicated in an electrocardiographic series of 10,000 cardiac patients studied at the Massachusetts General Hospital (1916 to 1930).[1] Atrioventricular block was present in 641 patients (6.4%). The block was complete in only 79 (0.79% of the total series or 12% of the 641 patients). In most instances the etiological basis is not difficult to determine, coronary artery disease and rheumatic disease accounting for the great majority of cases. Unknown factors apparently are responsible for a few. This type of disturbance of rhythm is only rarely discovered at the time of its origin, and its discovery usually occurs accidentally in the course of routine health examinations or during the study of some cardiac or noncardiac illness. It is known that atrioventricular block, even of highest grade, is compatible with good health and full activity for many years. This is particularly true in the case of patients with congenital heart block who survive early childhood, and it is highly probable that the patient in case 1 falls in this category. On the other hand, it is recognized that heart block is usually more serious in older persons, in whom the disabling symptoms of the Morgagni-Adams-Stokes syndrome are likelier to occur.

In the two cases reported here certain factors stand out prominently. The slow rhythm was present in each patient for over 35 years. The defect in no way interfered with the patients having active, full lives. The etiology in each case remains unknown, unless diphtheritic infection in childhood in the second patient is presumed to be the cause. Following this assumption, the block must be assumed to have persisted for over 56 years without causing disabling symptoms. Similar reasoning may be applied in the case of the first patient. Here a slow pulse rate was detected during early childhood, but acute infectious diseases had been conspicuously absent. Apparently, in patients in whom complete heart block is not definitely related to diffuse myocardial injury and in whom attacks of syncope have not been a factor, the disease per se may persist for a much longer time than has been hitherto suspected, producing little or no disability.

SUMMARY

Two cases are reported of complete atrioventricular block lasting for 35 years or more in women in their late fifties, who continued in good health, free of any important symptoms, during that period. One patient died suddenly last year, and the pathological diagnosis of her condition is reported. The other patient continues to be well. These two cases illustrate the fact that such a disturbance of rhythm is compatible with long life and good health.

DUPLICATION OF THE STOMACH

REPORT OF THE FIFTH CASE RECORDED

Jorge de Castro Barbosa, M.D.
V. Bicudo de Castro, M.D.
Nicola Caminha, M.D.
Candido de Oliveira, M.D.
and
Carlos Ramos, M.D., Rio de Janeiro, Brazil

Ladd and Gross [1] defined duplications of the alimentary tract as ". . . spherical or elongated hollow structures, which possess a coat of smooth muscle, which are lined by a mucous membrane, and which are intimately attached to some portion of the alimentary tube." The most comprehensive study of these lesions thus far published was made by those authors.

These cysts have been given different names, such as "enterogenous cysts," "enteric cysts," "enterocystomas," "inclusion cysts," "ileum duplex," "giant diverticula," and "gastrogenous cysts." None of these, however, is satisfactory enough to be used as a common designation for all these similar abnormalities of common embryologic derivation or developmental aberrations, regardless of location. The term, "duplications of the alimentary tract," preferred by Ladd and Gross, seems to be the most satisfactory.

Lesions of this type have been encountered in all levels of the digestive tract, from the base of the tongue to the anus. Almost every level is represented by one or more cases in the series of 18 collected by Farber [2] at the Boston Children's Hospital. As reported in the literature, the commonest site of occurrence is the small intestine. These duplications are found in relation to the terminal portion of the ileum more commonly than in any other part of the gastrointestinal tract.

CASES DESCRIBED IN RECENT LITERATURE

The first recorded case of duplication of the alimentary tract situated along the stomach was that of Ladd and Gross in 1940.[3] The second recorded case was one in which an enterocystoma of the stomach occurred in a 6-month-old child, and was reported by Ferraro in 1942.[4] The third case, in which the lesion was called "reduplication of the stomach," was reported by McCutchen in 1949.[5] The anomaly occurred in a man 27 years old. In 1951, Høyer and Andresen [6] reported an anomaly of the stomach that never had been observed before: a communicating duct between the cardiac region of the stomach and the duodenal bulb. Since this duct had two muscular coats and its lumen was lined with gastric mucosa, it constituted a hollow structure that could be considered a duplication of the stomach. The case we are presenting is, as far as we know, the fifth recorded case of gastric duplication.

PATHOLOGICAL ASPECTS

Adequate knowledge of the pathological aspects of these interesting lesions is essential to the surgeon who is called on for operative treatment. Duplications of the alimentary tract are replicas of, and are intimately attached to, some segment of the digestive tract. They share with this particular segment, at the area to which it is contiguous, the same smooth-muscle coat. At the free surface of such a process smooth muscle also can be found in its wall. The lining of these hollow structures is formed of mucosa or epithelium, similar to that of some portion of the stomach, small bowel, or colon. The duplication is not, however, necessarily a perfect replica of that viscus to which it is contiguous. A duplication of the stomach, for instance, can have a lining similar to intestinal mucosa and vice versa. A cyst of the rectum may have gastric epithelial lining, and so forth. Variations in the epithelial lining can be caused by pressure from entrapped, clear, colorless, mucoid fluid, secreted by the membrane of the cyst. This pressure may become so great as to cause necrosis and sloughing of the epithelial lining, which would add blood to the fluid. Any communication between the cyst and the digestive tract, which is not usual, naturally would permit the passage of digestive contents into the cyst.

As was particularly well evidenced in the case to be presented, it is of considerable practical surgical importance to differentiate (1) duplications of the alimentary tract and (2) lymphatic mesenteric cysts. Cysts can be shelled out easily from the mesentery, without disturbing the neighboring segment of the gastrointestinal tract. When enterogenous cysts and duplications of the alimentary tract are encountered, however, there is, in general, no plane of cleavage into which the surgeon can dissect, in order to peel away the cyst from the adjacent viscus. Any resolute attempt at such a maneuver would

result in cutting into and opening either the duplication or the contiguous viscus.

Ladd and Gross [1] presented a particularly illustrative photomicrograph of the wall of a duplication attached to that of its adjacent sister viscus. Between these two walls were shown the intermixed common smooth muscle coats, without any plane of cleavage between them.

The size of the duplications varies according to location. The duplication reported by Ladd and Gross was characterized by colonic mucous membrane, and was situated at the base of the tongue; it was 1 cm. in diameter. Cysts situated along the duodenum or rectal wall may be encountered when they are still small, because the symptoms call attention to them early. Those situated along the stomach may attain a size equal to that of the stomach itself or even larger, as in our case. Those which occur along the small bowel may be very long, such as the one 38 cm. long (case 15 of Ladd and Gross [1]), but are not very wide. Those that develop along the sigmoid colon may be very large and yet cause relatively minor symptoms. In Weber and Dixon's [7] unique case the duplication involved the entire large intestine.

SYMPTOMS AND DIAGNOSIS

The symptoms caused by duplications of the alimentary tract arise from (1) obstruction, which produces colicky pain, visible peristalsis, and vomiting; (2) distention of the hollow structure, engendering a continuous sensation of fullness, made worse by the ingestion of food or actually producing pain; or (3) vascular obstruction, producing segmental infarcted areas along the alimentary tract, with consequent hemorrhage. When such duplications become large enough, they are palpable and give the examiner the impression of a rounded, smooth, fairly renitent, cystic mass, which usually is movable and nontender when not too tense.

Roentgenologic examination with contrast medium can be of considerable aid in the differential diagnosis of these structures. Roentgenograms of course cannot disclose the histological nature of the mass, but they may permit the conclusion that the mass is intramural and extramucosal. The latter diagnosis was made by Schatzki [8] when he examined the roentgenograms in our case made by one of us (N. C.).

TREATMENT

In view of the pathological data previously mentioned regarding the absence of a plane of cleavage between the involved viscus and its duplication, the surgical treatment of choice in nearly all cases is radical, entailing removal of the duplication and resection of its adjacent viscus, followed by immediate reestablishment of the continuity of the alimentary tube. Certain circumstances, however, depending on the size and location of the duplications, not to speak of the precarious condition of some patients, make this procedure too hazardous and out of proportion to the benignity of the lesions. This is especially true of lesions in the upper part of the gastrointestinal tract. Radical removal of the duplication concomitantly with resection of the adjacent viscus is feasible when the lesion is in the small intestine (which is fortunately the commonest site) and when it is in the colon. In the case of gastric duplication reported by Ladd and Gross [3] and in our own, radical resection would have entailed total gastrectomy followed by esophagojejunostomy. This would have been too formidable an operation.

Under such circumstances, other forms of surgical treatment can be carried out, such as opening and emptying of the cyst, followed by marsupialization, with or without partial excision. The cavity can then be packed tightly with gauze, and injected with a sclerosing or necrotizing solution to destroy the epithelial mucous membrane that lines the cavity.

Moreover, internal drainage such as is frequently applied to cysts of the pancreas could be established. This technique was used successfully by Gardner and Hart,[9] who established a communication between an enterogenous duodenal cyst and the contiguous duodenum. In cysts of larger size there would be the possibility of failure from inadequate drainage. With adequate knowledge of the pathological aspects of these structures, and in view of the supportive and other forms of therapy now available, the operative treatment of these lesions can be carried out with a low mortality rate and good long-range results.

REPORT OF CASE

A white woman, 33 years old, was admitted to our service on Jan. 5, 1951, where she was examined by one of us (V. B. C.). Six months prior to her admission, one morning before she had eaten, she had complained of severe epigastric pain. Subsequent ingestion of food had brought on repeated vomiting. Episodes of vomiting had occurred very frequently for the next 30 days. Her physician at that time had instituted parenteral alimentation. During the same period the patient had difficulty in bowel movements, which were accomplished only with the aid of enemas. Once there had been no bowel movement for a week, in spite of the use of laxatives. On one occasion during the month in question the patient had been unable to urinate for 24 hours. Catheterization finally relieved her of considerable distention of the urinary bladder. During the next 30 days she had felt much relieved, while taking medication prescribed by an attending physician.

The patient then noticed a small, nontender epigastric mass, which she could mobilize freely. During the next four months this mass gradually increased in size, until it finally occupied the whole left upper abdominal quadrant, became painful, and was no longer movable. The vomiting recurred, but was not so frequent as previously; small, frequent, oral feedings were possible. Once she vomited some black fluid-like material, which simulated coffee grounds. At the time of her admission, in addition to severe, continuous pain in the left upper abdominal quadrant, necessitating the use of opiates for relief, the patient complained of a dull ache in the left lumbar region.

As to pertinent data antedating the onset of the foregoing distress, the patient remarked on the occurrence of cancer in three aunts. She also said that for eight years prior to the time we saw her she had had a lesion on her face, characterized by periods of recrudescence and regression, just before and during menstrual periods, respectively. About four years prior to her admission, the patient was said to have had a gastric ulcer. She said she had vomited blood, but had been considered cured after following a medical regimen. Unfortunately the report of the roentgenologic examination of the stomach made at that time was not available. The patient also said that about two years previous to her visit she had had stones in the urinary bladder.

Palpation disclosed a large, rounded, apparently smooth bulge in the whole left upper abdominal quadrant. This bulging discretely accompanied the respiratory excursions and pulsated isochronically with the radial pulse. There was evidence of beginning venous collateral circulation over the abdominal wall.

[8] Schatzki, R.: Personal communication to the authors.

[9] Gardner, C. E., Jr., and Hart, D.: Enterogenous Cysts of Duodenum: Report of Case and Review of Literature, J. A. M. A. 104:1809-1812 (May 18) 1935.

This mass was globular, with definite delimitations and a smooth surface; it was of hardened consistency, only slightly movable, and very painful. The pulsation evidently was transmitted from the underlying aorta; there was *no* expansion as in aneurysms and no abnormal sounds. Percussion showed dullness over the whole surface of the large mass, except for a narrow, transverse, elongated strip of tympanicity, apparently referable to the transverse colon, between the area of dullness over the liver and the lower portion of the mass.

Lupus erythematosus involved the skin of the face, over the sternum, and on the anterior aspects of both forearms. All other findings were normal except for chronic cervicitis found during routine pelvic examination.

Results of urinalysis and a complete hemogram were normal. A few ova of Trichuris trichiura were found in the stools. Results of flocculation tests for syphilis were reported as doubtful. Values for blood urea and sugar were within normal limits. Roentgenograms of the thorax disclosed nothing abnormal. Cholecystograms were considered to indicate a normal gallbladder. Flat roentgenograms of the abdomen, however, showed a large mass occupying the left upper abdominal quadrant. The left kidney did not appear in these roentgenograms. The right kidney appeared to be normal. Excretory urograms showed both kidneys to be functioning normally. The left kidney was slightly enlarged, and its pelvis was not distended by the contrast medium. A roentgenogram made with the aid of a barium enema (fig. 1*A*) showed the splenic flexure to be pushed downward by a large extrinsic mass of increased density, which occupied the left hypochondrium. A blastoma of the body or tail of the pancreas was suspected. Roentgenologic examination of the stomach (fig. 1*B*) revealed a voluminous extragastric tumor mass that pushed this viscus forward; the impression was that a large pancreatic cyst was responsible. Aureomycin was administered for 72 hours before the operation.

On Jan. 17, with the patient under anesthesia with nitrous oxide, ether and oxygen, exploratory laparotomy was performed by one of us (J. C. B.), through a primary upper left rectus, muscle-splitting incision. There were no adhesions to the anterior parietal peritoneum. The stomach protruded anteriorly and the transverse colon was pushed downward by a mass situated behind the stomach. This mass was made accessible by sectioning of the gastrocolic omentum. A voluminous thick-walled cystic mass was ound, firmly attached to the posterior surface and greater curvare of the stomach from the prepyloric region to the fundus. s mass was adherent to the anterior surface of the pancreas nd duodenum and splenic pedicle and to the upper surface of the transverse mesocolon. The mass was freed from the body and head of the pancreas and duodenum and also from the mesocolon with relative ease. Attempts at freeing this mass from the tail of the pancreas and splenic pedicle caused severe hemorrhage from large veins; this was finally controlled after splenectomy.

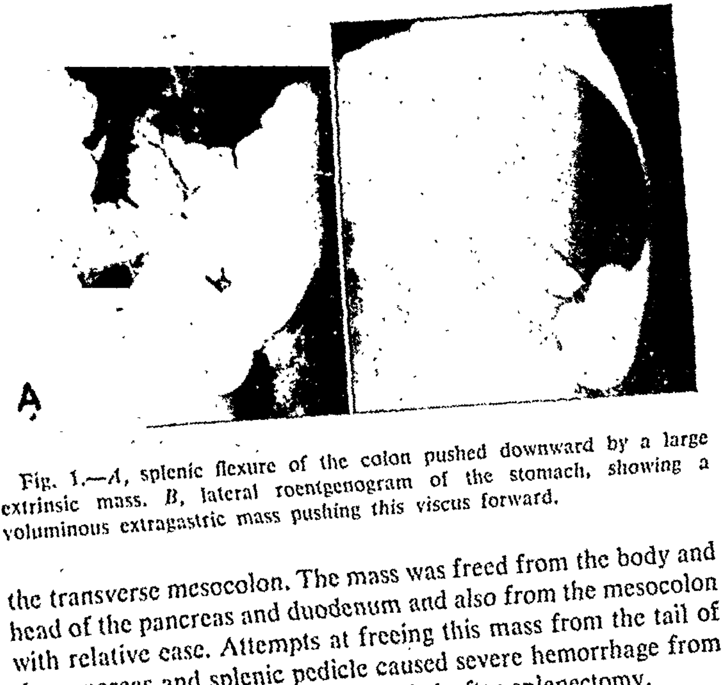

Fig. 1.—*A*, splenic flexure of the colon pushed downward by a large extrinsic mass. *B*, lateral roentgenogram of the stomach, showing a voluminous extragastric mass pushing this viscus forward.

The spleen was slightly enlarged. The cystic cavity was then opened anteriorly, and more than 2,000 cc. of clear, light yellow fluid of neutral reaction was aspirated. No communication with the stomach could be detected. At this point the walls of the cyst were completely free from neighboring structures except for the attachment to the posterior surface and greater curvature of the stomach, from which it could not be dissected free without cutting into it. This was avoided.

Fragments from different portions of the anterior wall of the cyst were given to the pathologist (Dr. E. T. Torres) for diagnosis by means of frozen section. Moments after the cavity of the cyst had been emptied, the walls contracted and became considerably thicker, measuring in certain portions about 12 mm. The cavity of the cyst then could accommodate only about 20 cc. of saline solution. The pathologist, Dr. Torres, found much fibrous tissue, intermixed with smooth-muscle fibers crossing in different directions.

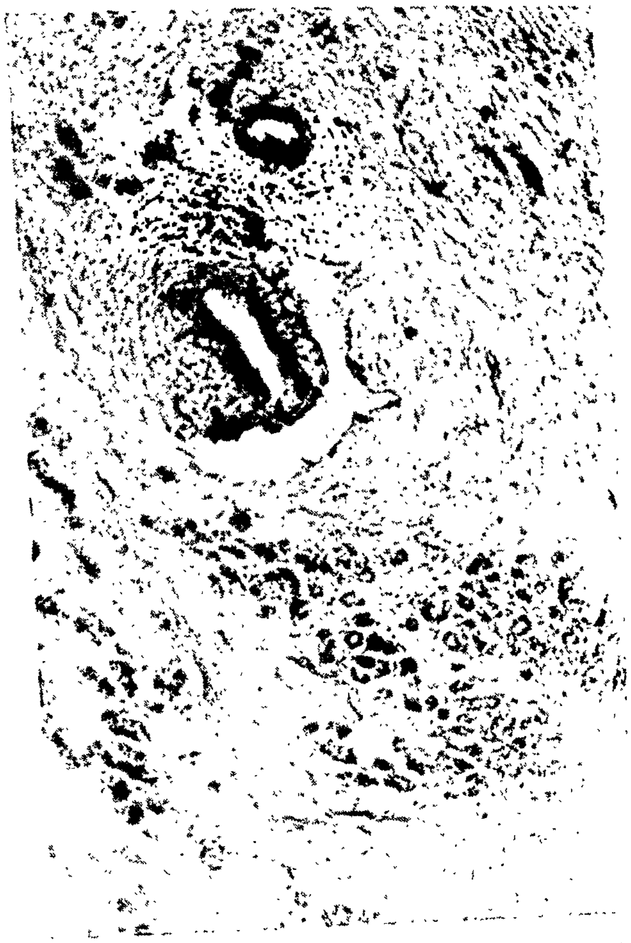

Fig. 2.—Fixed sections of fragments taken from a portion of the wall of the cystic mass, showing smooth-muscle fibers, fibrous connective tissue, and epithelial formations of small, atrophic, deep-staining epithelial cells.

An epithelial lining was searched for, but was not found at this time. Nevertheless, we realized that we were dealing with an exceedingly unusual lesion, namely, duplication of the stomach, and that to remove this lesion completely, total gastrectomy and esophagojejunostomy probably would be in order. We proceeded instead with a much less hazardous procedure, which consisted of partial hemispherical excision of the cyst, followed by its marsupialization to the anterior abdominal wall, after the lining had been painted with a 10% solution of formaldehyde. The cavity was then packed tightly with a long strip of iodoform gauze and the remaining portions of the incision were sutured with interrupted stitches of no. 0 and 1 chromic catgut in the peritoneum and fascia, respectively, with reinforcing cotton sutures in the fascia.

The pathologist reported that the fluid contents of the cys exhibited a positive (grade 4) Rivalta reaction, with a pH of 7 Microscopic examination of the fluid disclosed rare cells an numerous lymphocytes and erythrocytes. Multiple fixed section were made from fragments taken from various portions of th cyst. One of us (C. O.) finally detected epithelial formations (fig. 2), in addition to the involuntary muscle fibers and fibrous connective tissue previously detected in the frozen sections. The greater portion of the lining of the cyst had been destroyed by the great pressure from the retained fluid. The glands found were formed of small, atrophic, deep-staining epithelial cells. The nature of the cyst was thus more completely authenticated.

During the immediate 48 hours after the operation a state of shock persisted in spite of repeated use of analeptic agents and administration of blood. The extremities were cold and the systolic blood pressure oscillated between 85 and 95 mm. Hg. At the end of this period the patient improved considerably. She was up and about on the 10th postoperative day. The immediate and persistent state of shock was interpreted as being caused not so much by the operation as by absorption of the formaldehyde that was used to destroy the epithelial lining of the cyst. This provoked an "alarm syndrome" such as that described by Selye.[10]

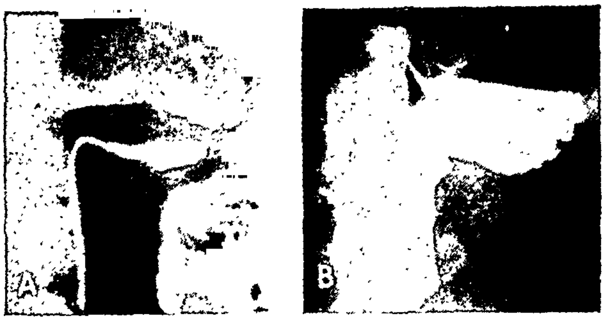

Fig. 3.—*A*, deep, narrow sinus tract at the site of marsupialization into which contrast medium was injected through a thin Nélaton catheter. *B*, the stomach, three months postoperatively, showing some deformity. The stomach, however, emptied normally.

Since the patient lived far from the hospital and needed careful daily dressings, she was purposely kept in the hospital longer than would otherwise have been necessary. The packing was removed two days postoperatively. The patient was dismissed from the hospital seven and a half weeks postoperatively. She was then taking regular meals and was feeling well, although she still had a long, narrow sinus at the site of the marsupialization (fig. 3*A*). This finally closed 30 days later. About three months later roentgenologic examination of the stomach (fig. 3*B*) showed some deformity but normal emptying. She had gained considerably in weight. At the time of this writing, 14 months postoperatively, the patient was feeling very well and complained only of occasional slight epigastric pain after a heavy meal.

COMMENT AND SUMMARY

The authors describe the fifth case of duplication of the stomach recorded in the literature. The patient was a 33-year-old white woman who complained of severe epigastric pain and vomiting and who had a large tender mass occupying the whole left upper abdominal quadrant. Roentgenologic examination of the stomach showed a voluminous extrinsic mass dislocating this viscus anteriorly. A large duplication of the stomach containing more than 2,000 cc. of fluid was partially excised and marsupialized to the anterior abdominal wall. Sections from the wall of the cyst showed much fibrous tissue, smooth-muscle fibers, and an atrophic, partially destroyed epithelial lining. The patient, except for minor symptoms after heavy meals, was well 14 months postoperatively.

URETERAL COMPRESSION DUE TO METASTASIS FROM CARCINOMA OF SIGMOID

George R. Krause, M.D.
and
Mortimer Lubert, M.D., Cleveland

Metastasis to retroperitoneal lymph nodes from carcinoma of the sigmoid colon or rectum may compress and obstruct the ureters, especially the left one. Two recent articles [1] mentioned this, but, unfortunately, there was not enough emphasis in either. One of the reports included cases with other sites of primary neoplasm; the other laid greatest stress on changes in position of the ureters that follow reperitonealization of the pelvic floor during an abdominoperineal resection of the rectum. Recent experiences have led us to believe that ureteral compression by metastasis from carcinoma of the sigmoid colon or rectum is of sufficient importance to deserve undivided attention.

During the past five years we have seen five patients who have had at least one ureter compressed by lymph nodes containing tumor that was metastatic from a carcinoma of the distal colon. The primary tumor had been removed from four of these patients, but they had returned to their physicians with various complaints. All described vague abdominal distress and distention. Some had actual pain; others mentioned troublesome constipation. None of the difficulties mentioned were referred to the urinary tract.

The initial investigation requested by the clinician was usually confined to a roentgen study of the site of operation, anticipating that a narrowing of the anastomosis or a local recurrence might be found to explain the symptoms. In no instance did this study answer the problem, even on repeated attempts. Studies of the upper gastrointestinal tract and the small intestine were often requested, but they did not reveal significant findings. After an intravenous urogram finally provided the answer in case 1, the other cases were evaluated correctly with less difficulty; this was done despite the fact that the clinician was frequently reluctant to consider study of the urinary tract as a possible solution of the problem. In the fifth case, routine investigation of the urinary tract prior to operation not only disclosed the presence of pressure on the left ureter but also enabled the surgeon to plan his procedure in advance and to accomplish his purpose more readily.

REPORT OF CASES

Case 1.—A 41-year-old white man was admitted to Mount Sinai Hospital on June 1, 1946, for resection of an adenocarcinoma that was about 2 in. (5.08 cm.) above the peritoneal reflection. Lymph nodes felt in the mesosigmoid were removed with a large section of the mesentery; two deeper nodes were also removed. All contained metastatic tumor. Three months later, because of abdominal cramps and distension, a barium study of the colon was done. This did not reveal evidence of significant narrowing at the anastomosis, dilatation of the colon, or stasis, even when repeated three weeks later.

From the Department of Radiology, Mount Sinai Hospital.

C.: Medial Deviation of the Ureters Complicating Carcinoma of the Rectum and Sigmoid, and Proctosigmoidectomy, Surg., Gynec. & Obst. 93: 273-282, 1951.

Six months after surgery, the patient complained of constipation and severe, constant pain in the left lower quadrant. After a third normal barium enema, the medical consultant requested an intravenous urogram, which revealed no excretion of the dye by the left kidney. Ureteral catheterization (fig. 1) then demonstrated three points of obstruction in the left ureter.

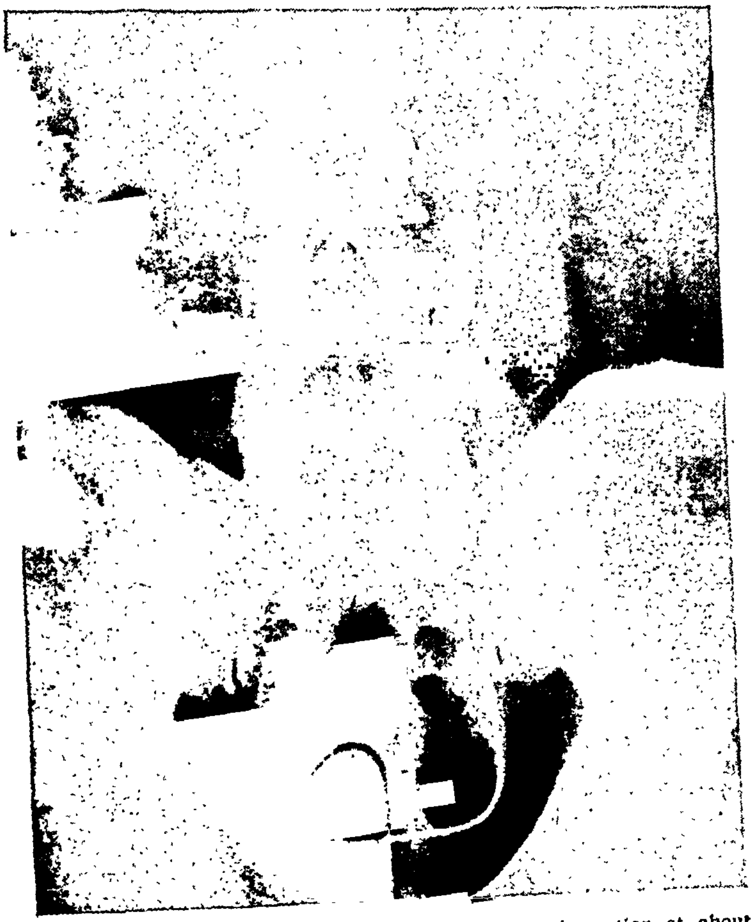

Fig. 1 (case 1).—The ureteral catheter met an obstruction at about 10 cm. There are two more distinct, narrowed areas higher up (arrows). The small amount of dye in the kidney pelvis reveals hydronephrosis. At exploration, the ureter was encased in tumor tissue at the points of constriction.

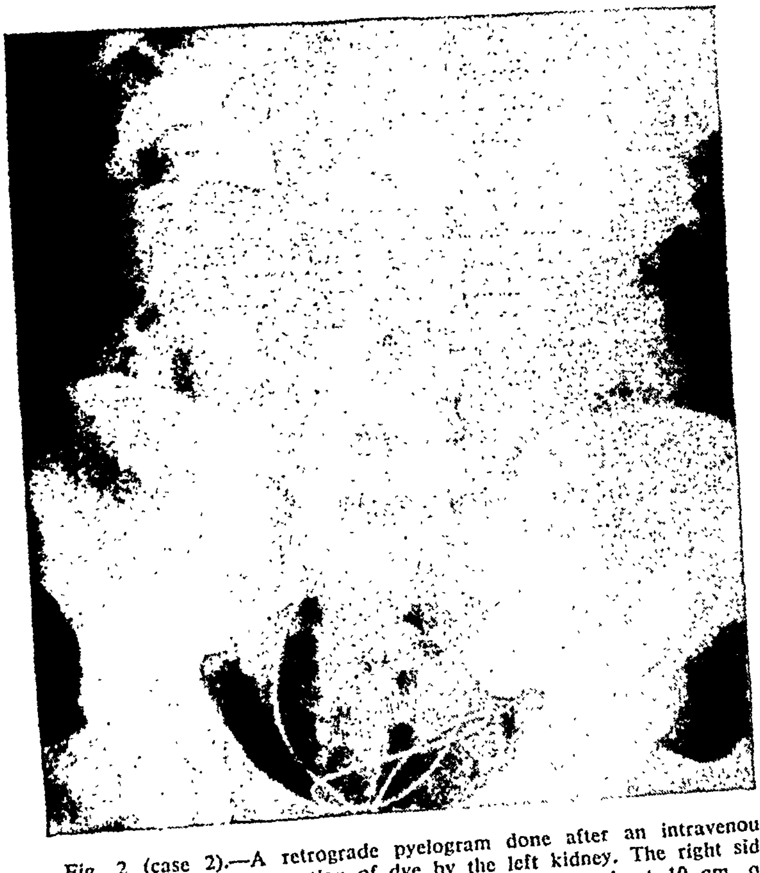

Fig. 2 (case 2).—A retrograde pyelogram done after an intravenous urogram revealed no excretion of dye by the left kidney. The right side was normal. The catheter was completely blocked at about 10 cm. on the left. Dye was extravasated when the catheter perforated the ureter.

Because of the severe pain and demonstrable infection, a left nephrectomy and a ureterectomy were done. The ureter was encased in tumor tissue at points corresponding to the constrictions seen in figure 1. The patient died in another hospital, 10 months after the original colon resection.

Case 2.—A 43-year-old white man was admitted to Mount Sinai Hospital on April 23, 1947, for resection of a carcinoma of the sigmoid, which was 1 in. (2.54 cm.) above the peritoneal reflection. A number of small nodes were present in the mesosigmoid; microscopic examination did not reveal evidence of tumor. Fourteen months later he complained of persistent, but diffuse, abdominal distress. Barium studies of the colon and the upper gastrointestinal tract did not reveal any abnormality. Because of our experience with case 1, we requested that an intravenous urogram be done; this revealed that no dye was excreted by the left kidney. Subsequent ureteral catheterization revealed a partial block of the left ureter at 10 cm., with dilatation of the urinary tract above it. Three months later (fig. 2) a catheter could not be passed up the left ureter beyond that point. Two months later (now 19 months after the original surgery) a hard mass could be palpated deep in the right lower quadrant. An intravenous urogram at this time revealed hydronephrosis and hydroureter on the right, with no dye excretion on the left. The patient died of uremia soon afterwards, 21 months after the colon resection.

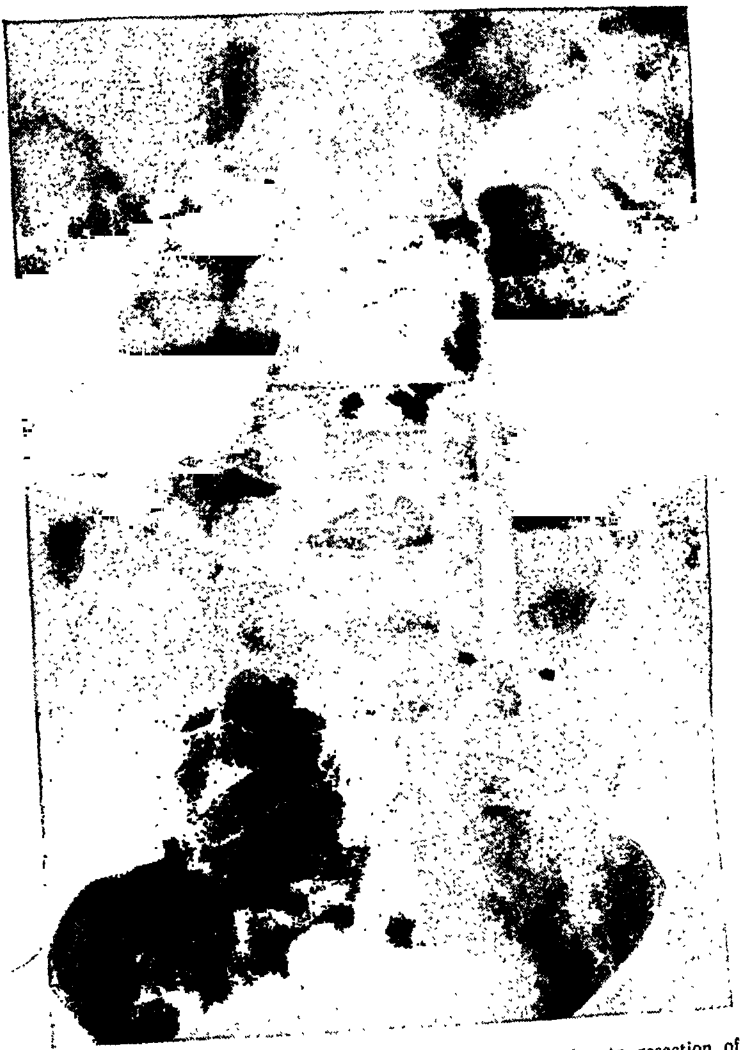

Fig. 3 (case 5).—An intravenous urogram done prior to resection of the sigmoid reveals a left hydronephrosis and hydroureter. The ureter is dilated down to the sacrum (arrows). The site of obstruction was confirmed by ureteral catheterization. At surgery it was found to be caused by metastatic tumor compressing the ureter.

Case 3.—A 52-year-old white man was admitted to Mount Sinai Hospital on Jan. 8, 1948, for resection of a small, constricting carcinoma of the sigmoid, 3 in. (7.62 cm.) above the peritoneal reflection. Nodes could be palpated deep in the mesosigmoid. Four of those removed were examined microscopically and found to contain tumor.

The patient remained in fairly good health for about 18 months but then complained of pain in the left lower quadrant, which was aggravated by standing and more severe after a bowel movement. A barium enema did not reveal evidence of narrowing at the anastomosis. An intravenous urogram, done at our request, showed that no dye was excreted by the left kidney. The ureteral catheter encountered a complete block at 10 cm. Later, repeated barium studies were again reported as normal.

Twenty-six months after the original resection, he was reoperated for intestinal obstruction. Exploration revealed many adhesions and tumor implants on the peritoneum. There were tumor masses at the root of the mesentery; the left ureter was encased in such a mass. The obstruction, largely due to the adhesions, was relieved, but the patient died at home, 30 months after the original resection.

CASE 4.—A 50-year-old white woman was admitted to Mount Sinai Hospital on Jan. 11, 1949, for resection of a carcinoma of the sigmoid 3 in. (7.62 cm.) above the peritoneal reflection. The mesosigmoid contained 17 lymph nodes; tumor was demonstrated in two of them on microscopic study. (Clearing techniques on the mesosigmoid were not done on any of these specimens.) In the ensuing months she complained only of fatigue and required mild laxatives. Later, because of pain and vague abdominal complaints, three barium studies of the colon and the small intestine were done; none revealed significant abnormalities. We suggested that an intravenous urogram be done, but none was ordered.

Thirteen months after surgery, she became lethargic and vomited repeatedly. After catheterization revealed an empty bladder, ureteral catheters were inserted. A partial, but passable block was encountered on the left at 7 cm.; a complete block was found on the right at the same level. The blood nonprotein nitrogen was 174 mg. per 100 cc. An indwelling catheter on the left side resulted in a temporary reduction in nitrogen retention, but she died of uremia 16 months after the sigmoid resection.

CASE 5.—A 62-year-old white woman was admitted to Mount Sinai Hospital on Oct. 13, 1951, for a resection of a carcinoma of the sigmoid. She complained of increasing constipation and vague abdominal distress; no symptoms were referable to the urinary tract. A routine intravenous urogram was done prior to surgery (fig. 3). The upper urinary tract was dilated; the point of obstruction appeared to be in the lower ureter, near the pelvic brim. A catheter passed beyond the point of obstruction and drained considerable pus and urine. The carcinoma was resected with the catheter in place. The left ureter, found to be compressed by a tumor mass, was dissected free, and as much as possible of the metastatic tumor in this region was removed. The immediate postoperative course was uneventful.

COMMENT

Studies of the lymphatic spread of carcinomas of the distal colon [2] have been based largely on resected specimens. As a result, there has been a concentration of interest on the nodes in the mesocolon itself, with little, if any, stress laid on the relationship of the deeper nodes to the ureter. This is in contrast to similar studies of carcinoma of the cervix, in which the intimate relationship between the lymphatic drainage of the cervix and the ureters is emphasized and widely known. Indeed, because such spread is the usual occurrence in the natural (untreated) history of carcinoma of the cervix, operations have been devised to remove these nodes as part of the primary treatment.

Since the base of the mesocolon lies in intimate relation with the lower part of the left ureter, enlarged lymph nodes in the root of this mesentery may encase or compress the ureter. Further metastasis of tumor to periureteric nodes may involve the ureter at a higher level. Spread to the other side is also possible (cases 2 and 4).

Compression of the ureter occurs gradually, because the tumor growth in these lymph nodes is slow, so that the absence of urologic symptoms is not surprising. Because at first there is usually obstruction of the left ureter only, evidence of poor kidney function is not present. Unless infection supervenes, there will be no specific clinical or laboratory evidence or urologic difficulty. The symptoms do not point to the urinary tract, and, unless the pathogenesis of the syndrome is understood, the vague complaints will not suggest the need for intravenous urograms, and unnecessary delay will result.

Because the concept of cancer surgery has become progressively more radical, important implications may be drawn from our experience. Radical surgery for carcinoma of the sigmoid colon may one day include the periureteric area on the left, somewhat in the manner of Meigs' operation for carcinoma of the cervix.

Indeed, it may be found advisable at a later time to consider removal of the left kidney and ureter a part of the radical surgical approach to this lesion. (This is not possible in surgery for carcinoma of the cervix, since lymph node spread in that lesion may be bilateral at an early stage.) Such radical extension of the surgical treatment cannot be recommended as a prophylactic procedure until statistical study has determined the incidence of spread from carcinoma of the sigmoid to the nodes along the left ureter; however, such radical surgery might well be the only hope for a patient resembling case 5 or for one in whom there is definite evidence of such lymph node metastasis at the time of surgery, even if it is not compressing the ureter at the time.

CONCLUSIONS

1. Intravenous urography is an important procedure, preoperatively and postoperatively, in the management of carcinoma of the sigmoid colon.
2. A more radical surgical approach to carcinoma of the sigmoid colon, either as a primary or palliative procedure, may prove to be necessary.

Energy Available in Alcohol.—Alcohol has an energy food value of seven calories per gram. Approximately 90 per cent of ingested alcohol is oxidized to carbon dioxide and water, the remaining 10 per cent accounting for the smell of alcohol on the breath, and alcohol in the urine, perspiration and saliva. The body can oxidize seven to 10 grams of alcohol per hour, which corresponds roughly to 1 oz. of whiskey or 8 oz. of beer. Thus, the maximum energy available in a 24-hour period from the oxidation of alcohol alone, is about 1600 calories.—Bell, R. G., M.D., Clinical Orientation to Alcoholism, *Industrial Medicine and Surgery, The Journal of Medicine in Industry*, June, 1952.

COUNCIL ON PHARMACY AND CHEMISTRY

REPORT TO THE COUNCIL

The Council has authorized publication of the following reports.

R. T. STORMONT, M.D., *Secretary.*

STATUS OF PRIMAQUINE

1. MASS THERAPY OF SUBCLINICAL VIVAX MALARIA WITH PRIMAQUINE

Alf S. Alving, M.D., Chicago
Major John Arnold (MC), Army of the United States
Major Donald H. Robinson (MC), United States Army

This report deals with the problem in mass therapy presented by the large number of cases of vivax malaria occurring in the United Nations forces in Korea since 1950.

Because malaria is not a single disease but instead is a complex of diseases all caused by a member of the genus plasmodium the unique properties of the members of the various species and strains of the organism must be considered in any given therapeutic problem.

On morphologic grounds, four distinct species of plasmodia are recognized. One species, Plasmodium ovale, is rare and of little clinical importance; two species, P. malariae and P. vivax, have many properties in common. For therapeutic purposes, they may be considered together. The remaining species, P. falciparum, has special properties and must be considered separately.

On physiologic grounds, each species is made up of several strains, each with idiosyncrasies that modify response to treatment. It is unfortunate that differences in strains can usually be classified only by geography and can be considered in therapy only in the most general way. This means that drugs chosen for mass therapy must be sufficiently effective to cover variations in responses of strains.

These general considerations constitute only part of the problem faced in evaluation of antimalarial drugs.[1a] The following discussion emphasizes those factors that are of special importance in planning a program for the eradication of malaria in troops prior to their return to the United States.

CHOICE OF TREATMENT IN RELATION TO THE TYPES OF MALARIA

P. Falciparum.—P. falciparum appears to be the most recently acquired malaria infection in man. This is reflected in the fact that P. falciparum causes the greatest mortality and has the simplest life cycle of all malarias in the human host.

This simplicity of life cycle has proved to be of great importance in therapy. Very shortly after the parasite is introduced into man by a mosquito bite it disappears from the blood and enters the tissues of the host (fig. 1). Sometime within the first week of infection the tissue forms give rise to the easily recognized blood stages which usually are the only forms capable of producing symptoms. After producing this first brood of blood forms, the tissue stages either disappear or become nonfunctional. Blood forms arise only once in the course of any given infection with P. falciparum. For this reason, total eradication of P. falciparum can be achieved by simple eradication of the blood stages.

In practice, eradication of blood forms is usually easy, because most of the common antimalarial drugs have an action directed chiefly against the blood forms (schizonts). Such drugs, acting solely against the blood forms, are called suppressive agents. Of the newer suppressive drugs, chloroquine (aralen®), amodiaquine (camoquin®) and chlorguanide (paludrine®) have largely displaced quinacrine (atabrine®) and quinine in military use.

P. Vivax.—In contrast to P. falciparum, infections with P. vivax are much better adapted to the human host. This improved adaptation of parasite to host has led to a lower mortality rate but a higher degree of persistence, which has been achieved by the development of another stage in the life cycle of the parasite. P. vivax begins, like P. falciparum, as a tissue infection which lasts approximately one week, at the end of which time the blood forms causing the primary attack are produced (fig. 2). From this point on an important difference between P. falciparum and P. vivax appears. In the latter infection, a persisting tissue stage develops which, by giving off broods of blood forms at intervals, accounts for the periodic relapses of vivax malaria.

All the suppressive drugs effective against the blood forms of P. falciparum are effective against the blood forms of P. vivax. Thus, drug therapy of the acute disease from either parasite is usually the same, but the long-term result of such therapy is quite different. In P. falciparum infections, adequate suppressive therapy eliminates the disease for all time; in P. vivax infections, suppressive therapy eliminates symptoms of the disease until the next relapse.

If suppressive agents are taken continuously and in sufficient amounts, the blood forms produced in P. vivax infections at intervals by the persisting tissue stages are destroyed soon after they are formed and the patient remains well. Because vivax malaria is a self-limiting disease, through the development of immunity or the exhaustion of the tissue stages, continuation of suppressive medication for several years after leaving a malarious area will result in a reduction of the relapse rate. In endemic areas, continuous suppression can be carried out successfully for years provided a break in drug administration does not occur. Such long-continued suppression requires continuous vigilance. This is difficult even in endemic areas but is usually impossible for individuals or organizations returning to nonendemic areas where the stimulus for continuous therapy is lacking.

RADICAL CURE OF VIVAX MALARIA

To meet the problem produced by the constant threat of relapse from vivax infections in persons leaving an endemic area for a nonendemic area, another class of antimalarial drugs is of value. This class of drugs acts by destroying the tissue stages of the disease and thereby prevents the development of the blood form responsible for the relapse. Since they completely eliminate all trace of the infection, these drugs are called curative as opposed to the suppressive drugs which destroy only blood forms. Unfortunately, the curative drugs now known have very little effect against the blood forms and must be used in conjunction with one of the suppressive drugs when blood forms of the disease are present.

Of the thousands of drugs studied for antimalarial action, only members of the 8-aminoquinoline family closely related to pamaquine have shown a significant amount of curative activity. A number of compounds of this family possess some degree of action against the tissue stages of malaria, but only one of these compounds has shown a high enough level of activity with a low enough level of toxicity to warrant its use on a large scale. This compound, 8-(4-amino-1-methylbutylamino)-6-methoxyquinoline, now known as primaquine, was synthesized at Columbia University during the World War II antimalarial program.[1] After the wartime program was terminated, primaquine received extensive animal studies at The Christ Hospital, Cincinnati,[2] clinical tests at Stateville Penitentiary and the Federal Penitentiary at Atlanta,[3] and actual field trials in Nicaragua.[4] Large scale toxicity studies

at Fort Knox and Fort Benning jointly conducted by Army, United States Public Health Service, and civilian investigators later established the relative safety of administration of primaquine to troops on full active duty.[5]

MALARIA IN KOREA

The first large-scale problem of relapsing malaria in nonimmunes since World War II developed as a result of the hostilities in Korea in the summer and fall of 1950. Although malaria has been known to exist in Korea, the heavy infection of United Nations troops was largely unexpected. Previous experience by the 24th Corps on occupation duty in South Korea in 1947 revealed a variable amount of the disease among the civil population. Civilian surveys gave an incidence ranging between 0.97 and 33.94%.[6] The Japanese recognized malaria in their long experience on the peninsula but had not been impressed by the incidence. Certainly, when judged by the yardstick of experience gained by military forces in the Southwest Pacific, malaria in Korea did not seem to be a serious hazard.

Even so, the United Nations command used chloroquine (or chlorguanide) in the early days of fighting and effectively suppressed most of the infections present in the field. This treatment so obscured the disease that an evaluation of the size of the malaria problem was not possible until the troop rotation program was inaugurated in 1951, and large numbers of men were returned home and discontinued chloroquine suppression.

By virtue of Korea's temperate climate it would be expected that most Korean malaria would be vivax in type and would behave like the other temperate zone strains of vivax, such as the St. Elizabeth strain in the United States.[7] Since temperate zone strains of vivax malaria do not have morphologic characteristics that distinguish them from the tropical zone strains of vivax, a determination of the temperate zone character of malaria requires a study of the strain's natural history. In figure 3 the temperate zone vivax is compared with the tropical zone vivax. As can be seen in this figure, the chief difference between the two types appears in the relative length of the interval between the primary attack and the first relapse. The temperate zone vivax has a long latent interval of eight to nine months and seems adapted to the long winters of temperate zones during which malaria is not transmitted. This characteristic modifies the monthly incidence rates of the disease caused by the two forms of plasmodium vivax. In groups chiefly infected during the summer months with temperate zone vivax the incidence rates fall sharply in the winter months, whereas in groups infected with tropical zone vivax, even when transported to a temperate zone, the relapses will hold the attack rate relatively high at any season of the year.

Fig. 1.—An outline of a disease mechanism which seems adequate to explain the sequence of events in falciparum malaria and the mode of action of the more important antimalarial drugs

The presence of temperate zone vivax was suggested by the experience in 1947 of the 24th Corps in Korea which reported a spontaneous drop in its attack rate after October of that year. The rate fell from a high of 50 cases per 1,000 per annum in summer and fall to 1 or 2 cases per 1,000 per annum for the rest of the year.[6] More recent experience with Korean malaria in returning American servicemen has confirmed the fact that

Korean malaria has a long latent interval after the first attack and thus closely resembles the American St. Elizabeth strain. Falciparum malaria is virtually unknown in Korea.

Recent Military Experience with Korean Malaria.—The characteristics of the Korean strain have been pointed out in detail because they explain why the 8th Army did not have an outbreak of malaria when it discontinued chloroquine suppression during the winter of 1950-1951. Without benefit of subsequent experience with Korean malaria, the absence of wintertime relapses then made widespread malaria infection in the Army seem unlikely. Nevertheless, the 8th Army returned to chloroquine suppression in the spring of 1951, but men evacuated to the United States from the 8th Army did not return to chloroquine. The returnees, who saw service in the summer of 1950, began to relapse throughout the spring and summer of 1951 (fig. 4). These relapses eventually suggested a very high rate of suppressed infection in the 8th Army.

The Army Malaria Mission to the Far East Command during August and September 1951 was undertaken to establish the feasibility of using primaquine for mass therapy on the rotatees from Korea.[8] Since these men had been on fairly successful chloroquine discipline until the time of embarkation from Japan it was expected that a malaria-free interval of approximately six weeks existed in which to eradicate the tissue stages of the infection and to prevent the expected clinical disease. Because it is impossible to determine which men are infected prior to a clinical attack, it is necessary to treat all men as if they have the disease.

In the light of present experience with primaquine, it was the opinion of the Mission, with the concurrence of the Malaria Subcommittee of the National Research Council, that primaquine should be given for a two week period in single daily doses of 15 mg. of base. In the beginning of this study the dose could be arrived at only by considering many factors, for no actual trials against Korean malaria with long-term follow-up had been possible. Although primaquine was carefully tested against Chesson strain vivax malaria, it is well recognized that differences in response to drugs exist among the many known strains and varieties of malaria. The most persuasive reason for choosing the 15 mg. dose was that this dosage represents the maximum that can be given to large groups without special medical supervision. The most dangerous toxic effect so far

---

[8] The success of this mission was due to the splendid cooperation of the Army medical officers in the Far East Command, the Japanese Log. Command, the Eighth Army, the Second Log. Command and the Navy officers assigned to the Military Sea Transport Service. The mission is especially indebted to Colonel Arthur H. Long, consultant in preventive medicine to the Surgeon, Far East Command, whose extensive knowledge and experience with the medical and administrative problems of the Far East Command proved invaluable.

recognized has been the special susceptibility of some Negroes to hemolytic reactions to primaquine in doses greater than 15 mg. of base per day.[9]

Rotation Program.—An essential part of the success of a mass therapy program depends on the administrative obstacles involved. Accordingly, the troop rotation program was analyzed in detail to find the most promising two week period in which to give primaquine. Since many exceptions exist in the routine rotation program, it was apparent that all men could not be included without overwhelming administrative difficulty. The optimum period for giving the drug to the greatest number of men under the present system of rotation appeared to be from the time of each man's arrival at the replacement depot in Japan to the end of the 14 days of treatment, which would usually occur some time at sea. Because shipboard therapy made additional complications for the routine use of primaquine, the clinical investigations reported here were made aboard ship.

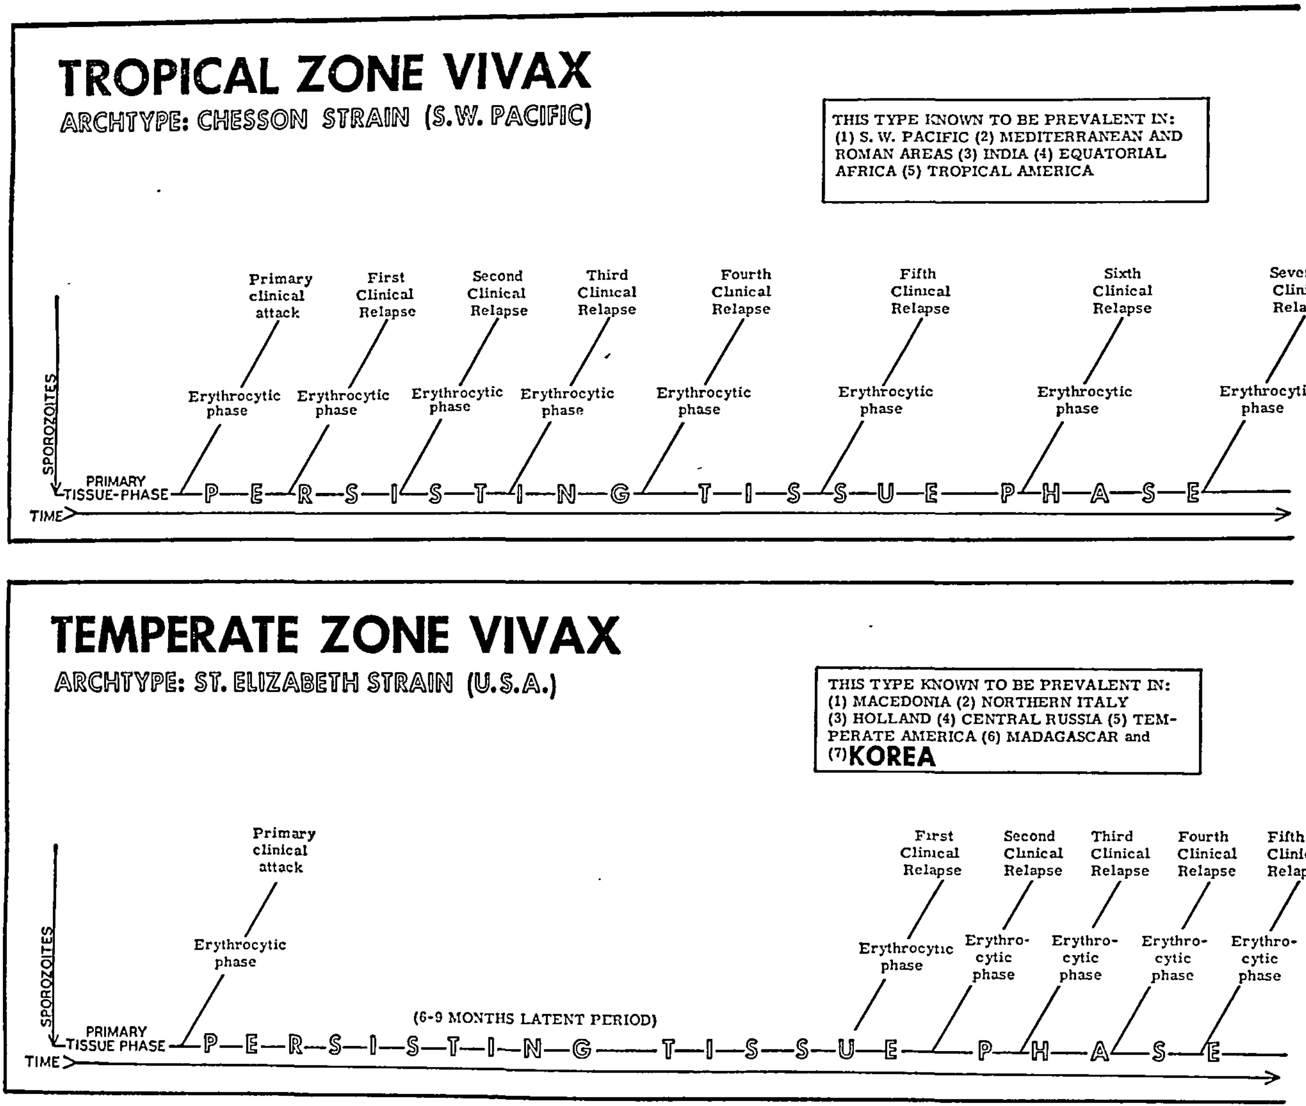

Fig. 3.—Two chief types of vivax malaria showing characteristic relapse patterns when each attack is treated by suppressive drugs.

CLINICAL TRIALS WITH PRIMAQUINE

Two independent clinical trials were performed under actual rotation conditions to determine: (1) the feasibility of continued administration of primaquine (15 mg. of base daily) to large groups of men without special medical supervision, (2) whether primaquine toxicity increased the incidence of motion sickness, (3) the effect of motion sickness on the ability to take and retain medication, and (4) whether primaquine begun on land would show enough cumulative toxicity to affect the motion sickness most common during the first four days at sea.

Studies Aboard U. S. N. S. Sgt. Sylvester Antolak.—The 1,493 officers and men on the U. S. N. S. Sgt. Sylvester Antolak, sailing from Sasebo, Japan, to Seattle on Sept. 18, 1951, were chosen for the first clinical trials. They were divided into two groups. One group of 742 officers and men, of which 16.9% were Negroes, was given primaquine (15 mg. of base daily) for 12 days immediately before the noon meal each day. The other group of 751 men received a placebo under the same conditions as the first group. Men received the pills even if they did not eat the noon meal. All cases of seasickness severe enough to send a man to sick call were evaluated and recorded. The voyage was rougher than the average Pacific run for that season.

Results of Clinical Trial.—Forty-six men in the primaquine group (742 officers and men) reported for seasickness; exactly the same number of men (46) from the control group of 751 officers and men also reported for seasickness. Only 3.9% of all men aboard missed one or more tablets. This means that 96% of all men aboard received either primaquine or placebo for 12 days without interruption. There was no sign of toxicity. None of the Negroes showed any evidence of hemolysis.

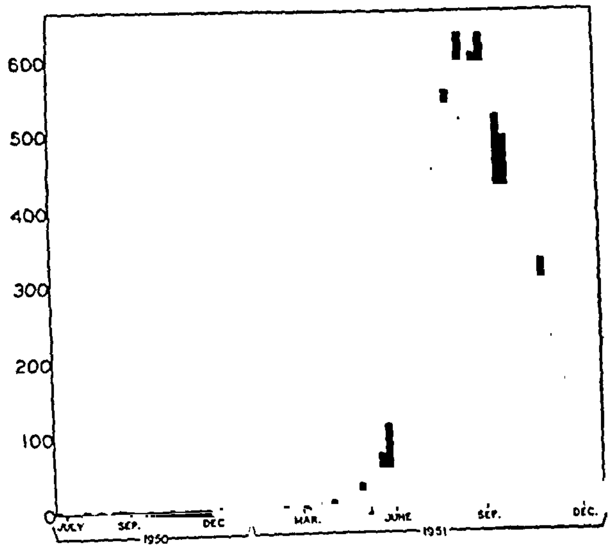
Studies Aboard U. S. N. S. Marine Phoenix.—This second study was arranged to test the effect of cumulative toxicity (which would come, if at all, 3 or 4 days after starting therapy) on motion sickness. Accordingly, after the U. S. N. S. Antolak sailed, the next 3,000 men processed at the Sasebo Replacement

---

[9] Hockwald, R. S.; Arnold, J.; Clayman, C. B., and Alving, A. S.: Toxicity of Primaquine in Negroes, J. A. M. A. this issue, p. 1568.

Depot (Prov.) were started on primaquine (15 mg. of base) once daily as soon as they arrived at that installation. From this group, 2,785 eventually sailed on the U. S. N. S. Marine Phoenix bound for Seattle. Members of this group spent a variable length of time at the Replacement Depot. Twenty-nine per cent had been at Sasebo 10 days before sailing and consequently received 10 pills before embarking. The remainder spent two to nine days at the depot prior to sailing.

The U. S. N. S. Marine Phoenix sailed Sept. 23, 1951. Two thousand sixty officers and men, of which 7.6% were Negroes, were selected to continue primaquine while 725 men were given placebos. It was impossible to give either primaquine or placebo by the roster because of the complexity of shipboard living. The total number of men receiving either pill was counted each day. For other data it was necessary to resort to sampling techniques. Only men missing mess failed to receive primaquine or placebo, as both were given just prior to eating. Generally, the amount of seasickness was reflected in the number of men at mess on that day. The number of men in either group missing mess was taken as a measure of gastrointestinal distress. Every man in sick call each day was seen for possible signs of toxicity. This was an unusually rough voyage.



▲ FIRST SHIP LOAD KOREA VETERANS LANDED IN U S. MAY 5, 1951

Fig. 4.—Number of Army personnel hospitalized for malaria in the United States each week since onset of Korean conflict. (Source: Medical Statistics Division, Office of the Surgeon General, Department of the Army.)

Results of Clinical Trial.—There was no detectable evidence of toxicity among the 2,060 officers and men who received primaquine. The amount of seasickness in the primaquine group was closely paralleled by the amount among the controls. Eighty-two and one-tenth per cent of all men aboard received 13 to 20 pills consecutively. An additional 8.8% received all but one of the scheduled pills. This means that 90.9% received 12 or more pills with an interruption of not longer than one day. This is the minimum period considered necessary for adequate therapy.

CONCLUSIONS

The trials reported here demonstrate the feasibility of using primaquine as a curative antimalarial in large numbers of men without special medical supervision, even under the difficult conditions met with at sea. Because of the tremendous medical load produced by these relapsing cases of malaria, the Armed Forces adopted primaquine for the treatment of all servicemen returning from Korea after endorsement by the Subcommittee on Malaria of the National Research Council and the Armed Forces Medical Policy Council. The success of this program, however, will depend upon the administrative discipline instituted to enforce it and upon the proper indoctrination of medical officers and troops in the aims and desirability of strict adherence to the 14 day therapeutic regimen.

2. CURE OF KOREAN VIVAX MALARIA WITH PAMAQUINE AND PRIMAQUINE

Capt. Paul L. Garrison, Lieut. Daniel D. Hankey
Capt. Walter G. Coker, Lieut. Col. William N. Donovan
and Col. Bruno Jastremski, (MC), United States Army
G. Robert Coatney, Scientist Director, U. S. Public Health Service, Bethesda, Md.
Alf S. Alving, M.D., Chicago
Ralph Jones Jr., M.D., Philadelphia

In the summer of 1951, when large numbers of Korean veterans came down with vivax malaria, a study designed to compare the curative effectiveness of pamaquine and primaquine was initiated. This preliminary report presents the results of that study after 11 months of observation.

METHODS

All patients admitted to the station hospitals with vivax malaria between July 25, 1951, and May 1, 1952, were included in this study. The diagnosis was established in every case by demonstrating parasites in the peripheral blood in two nonconsecutive smears. When the diagnosis was established, patients were treated in rotation according to one of the following regimens:

Regimen A: Chloroquine.—A total dosage of 1.5 gm. of base was given in three doses of 0.3 gm. each during the first 24 hours, followed by a single dose of 0.3 gm. daily for two days.

Regimen B: Chloroquine Plus Pamaquine.—A total dose of 1.5 gm. of chloroquine base was administered as in regimen A. In addition, 27 mg. of pamaquine base was given daily in three equally divided doses for 14 consecutive days.

Regimen C: Chloroquine Plus Primaquine.—A total dose of 1.5 gm. of chloroquine base was administered as in regimen A. In addition, 15 mg. of primaquine base was given in a single dose daily for 14 consecutive days.

All patients were hospitalized for the duration of treatment and were observed daily for evidence of toxicity. A white blood count, hemoglobin concentration, and routine urinalysis were taken when the patients were admitted. These studies were repeated after one week, for patients treated with regimen B or C, and at the end of therapy. Additional studies were performed as indicated.

When treatment was completed, the patients were discharged to duty and followed as outpatients at intervals of approximately six weeks. At each follow-up visit, patients were interviewed and a thick film of peripheral blood was examined for parasites. When relapses occurred, patients were treated according to the regimen originally employed.

RESULTS

A total of 864 patients were treated. Of this group, 709 were followed for 4 to 11 months after treatment (see table). The clinical manifestations of the acute attack of malaria were rapidly controlled by chloroquine.

Sixty-four (27.6%) of 232 patients treated with chloroquine alone, and followed for more than 4 months, relapsed. Sixty-one of the 64 patients experienced a typical febrile relapse with parasitemia; three had parasitemia but no fever.

A typical clinical and parasitic relapse 54 days after the last dose of drug developed in one (0.4%) of the 246 patients treated with chloroquine plus pamaquine and followed for more than four months. This patient was treated again according to the original regimen. No further relapse has occurred during 134 days of observation.

From the Department of Medicine, University of Chicago (Dr. Alving) and the Department of Medicine, University of Pennsylvania (Dr. Jones), and the Section on Chemotherapy, Laboratory of Tropical Diseases, National Microbiological Institute, National Institutes of Health (Dr. Coatney).

This study is limited to observations conducted in the station hospitals at Fort Knox and Fort Benning under the auspices of the Research and Development Board of the Office of the Surgeon General of the Army. Important supplementary studies have been conducted by the Army in the station hospitals at Fort Dix, Fort Meade, Camp Breckenridge, and, by the Navy, at Camp Lejune.

None of the 231 patients treated with chloroquine plus primaquine and followed for more than four months has relapsed.

In the course of these studies, only minimal evidence of drug toxicity was observed. Mild generalized pruritus which subsided 4 days after the drug was stopped developed in one patient treated with chloroquine alone. A similar mild pruritus developed in one patient treated with chloroquine and primaquine. It disappeared after chloroquine was withdrawn, before therapy with primaquine was completed. Occasionally, a patient treated with chloroquine plus pamaquine complained of mild, crampy abdominal pain at some time during therapy. This was not of sufficient severity to warrant stopping the drug. There was no evidence of hemolytic anemia in any patient. Approximately 15% of the patients had a mild to moderate anemia (hemoglobin concentration of 8 to 12 gm. per 100 cc.) at the time treatment was instituted. In these patients, the hemoglobin concentration increased during therapy as the acute attack was controlled. There was a slight, but probably significant, increase in leucocyte count at the end of therapy in patients treated with pamaquine or primaquine. Methemoglobin determinations were not done; cyanosis was not observed.

Treatment of Korean Vivax Malaria

Patients	Regimen A, Chloroquine, 1.5 Gm. (Base)	Regimen B, Chloroquine, 1.5 Gm. (Base) Plus Pamaquine 27 Mg. per Day for 14 Days	Regimen C, Chloroquine, 1.5 Gm. (Base) Plus Primaquine 15 Mg. per Day for 14 Days
Total Number Followed..............	287	291	286
Number Followed 4 to 11 Months After Treatment..............	232	246	231
Number Followed 4 to 11 Months and Relapsed....................	64 (27.6%)	1 (0.4%)	0

DISCUSSION

Korean vivax malaria is the temperate zone type characterized by a long latent interval of 6 to 10 months following the initial infection.[1] All of the patients in this study acquired malaria in Korea during the summer of 1950. The attacks reported here occurred after the latent interval.

The relapse rate (27.6%) after treatment with chloroquine is lower than that reported for other strains of vivax malaria.[2] This can be explained partly by the fact that these studies were inaugurated late in 1951, near the end of the life span of the parasite.

It is apparent from these studies that 15 mg. of primaquine daily or 27 mg. of pamaquine daily for 14 days, given in combination with chloroquine, will prevent relapses in nearly all cases of Korean vivax malaria. It is reasonably certain that few, if any, of the patients treated with pamaquine or primaquine will experience a relapse during the summer of 1952, because the relapse rate was reduced from 27.6% after chloroquine to less than 1% after treatment with pamaquine and primaquine.

Both pamaquine and primaquine were well tolerated, and a significant difference in toxicity or in therapeutic effectiveness was not demonstrated. The dose of pamaquine (27 mg. per day) used in these studies was nearly twice as great as the dose of primaquine (15 mg. per day) so that an exact comparison of therapeutic effectiveness was not possible.

Primaquine is undoubtedly the drug of choice for curative treatment of Plasmodium vivax malaria because of the greater spread between the effective and the toxic dose. However, it is apparent that either pamaquine or primaquine in doses which do not produce significant toxicity will cure most vivax infections of Korean origin. Because primaquine and pamaquine are relatively ineffective in destroying the erythrocytic stages of the malaria parasite, these drugs should be given simultaneously with chloroquine for the treatment of an acute attack. Because of the greater toxicity to pamaquine exhibited by Negroes, this drug should not be used for treatment of an acute attack unless the patients are under close medical supervision and unless the hemoglobin is followed daily.

SUMMARY

In a study of the effect of pamaquine and primaquine on the relapse rate of vivax malaria acquired in Korea, 709 patients were treated at the time of an acute attack and were followed for 4 to 11 months after treatment. Of 232 patients treated with chloroquine alone, 27.6% relapsed at least once after treatment. In a group of 246 patients treated with chloroquine and 27 mg. of pamaquine daily for 14 days, one patient (0.4%) relapsed.

Relapses did not occur among 231 patients treated with chloroquine and 15 mg. of primaquine daily for 14 days. Significant toxicity was not observed during this study.

3. TOXICITY OF PRIMAQUINE IN CAUCASIANS

Capt. John H. Edgcomb, (MC), United States Army,
Alf S. Alving, M.D., Chicago

Primaquine, 8-(4-amino-1-methylbutylamino)-6-methoxyquinoline,[1] a new curative agent for vivax malaria, has recently been extensively tested in the Armed Forces. Since mid-December, 1951, veterans returning from Korea have received 15 mg. of primaquine base once daily for two weeks aboard Military Sea Transport ships after termination of weekly chloroquine (aralen®) suppression at the time of embarkation.[2] Chloroquine remains in the blood in effective concentration for several weeks; it suppresses clinical symptoms by eliminating the erythrocytic forms of the malaria parasite but does not prevent subsequent relapses. Relapses can be prevented, however, by the administration of primaquine, which acts primarily against the exoerythrocytic parasites. Thus, combined action of the two drugs has been exploited during the transpacific voyage to achieve radical cure of vivax infections before symptoms have developed. Primaquine, combined with chloroquine, has also been employed extensively in treating clinical attacks of vivax malaria in Army installations in the United States.[2]

Curative dosages of primaquine may vary from 10 to 30 mg. of base administered daily for two weeks. The ideal dose within this range depends on several factors, including the species and strain of the infecting parasite, the degree of natural or acquired immunity of the individual, and the density of the sporozoite inoculum. Ten milligrams may produce radical cure in persons having great immunity.[3] Limited experience with the Korean strain of vivax malaria indicates that 15 mg. is probably sufficient to cure over 99% of patients [2] (table 1). Twenty-two and one-

* Primaquine should be given with meals. The third dose of chloroquine should be administered approximately 24 hours after the initiation of treatment. The blood hemoglobin *concentration* should be determined for any patient whose urine is of extremely dark or brown color.

half milligrams cures practically all persons heavily infected with the Chesson (Southwest Pacific) strain of vivax malaria under experimental conditions.[4] Thirty milligrams may conceivably be necessary to cure nonimmune persons infected by unusually large sporozoite inocula. Therapy during a clinical attack should include concurrent administration of quinine or chloroquine, of which the latter is recommended.

STUDIES AT STATEVILLE PENITENTIARY

Since early 1948, 699 light-skinned Caucasian adult male volunteers have received primaquine at the Illinois State Penitentiary (Stateville Branch). The men varied in weight from 130 to 260 pounds, the mean being 161 pounds. Three hundred and thirty-five were either noninfected or were treated in the latent interval between clinical attacks of malaria. The remaining 364 volunteers were treated during a clinical attack (table 2).

The following is a report of the toxicity of primaquine observed during these studies.[5] Parallel studies of pamaquine were used as a control. General procedures during these observations followed those outlined by Alving and co-workers.[6] Details of drug regimens and laboratory procedures are described below.

DRUG REGIMENS

Primaquine was administered orally as the diphosphate salt containing 56.9% of base. *Dosages of all drugs are expressed in terms of base weight.*

Primaquine was administered in programs utilizing single or divided daily dosage schedules. Daily dosage ranged from 10 to 240 mg., administered for 5 to 14 days. In addition, single doses of 30 mg. of primaquine were given weekly and semiweekly for 52 weeks together with chloroquine.

Garrison, P. L., and others: Cure of Korean Vivax Malaria with Pamaquine and Primaquine, J. A. M. A., this issue, p. 1562. In addition to the major studies at Fort Knox and Fort Benning, important trials of primaquine are being conducted at Camp Breckenridge, Fort Dix, and Fort Mead under the auspices of the Army and at Camp Lejune in cooperation with the Navy.

[4] Edgcomb, J. H., and others: Primaquine, S. N. 13,272, A New Curative Agent in Vivax Malaria: A Preliminary Report, J. Nat. Malaria Soc. 9:285-292 (Dec.) 1950.

[5] Earlier toxicity studies were performed in primates by Dr. Leon H. Schmidt, The Christ Hospital Institute of Medical Research, Cincinnati.

[6] Alving, A. S., and others: Procedures used at Stateville Penitentiary for Testing of Potential Antimalarial Agents, J. Clin. Investigation 27: 2-5 (May) 1948.

Pamaquine was administered on similar schedules in dosages of 15, 31.5, and 63 mg. for 14 days.

The suppressive action of pamaquine, even at the maximum tolerated dose of 90 mg. daily, is inadequate to terminate attacks of malaria quickly or consistently.[7] Therefore, quinine was used as the standard concurrent suppressive antimalarial drug in testing potential curative agents during World War II. Although better suppressive agents have since been developed, quinine has been retained to make results of current studies comparable with earlier investigations. When chloroquine was substituted as the concurrent suppressive drug, clinical malaria was almost invariably terminated during the first two days.

During the standard two week treatment schedule, 180 men received 15 or 30 mg. of primaquine daily, together with 1 gm. of chloroquine, administered in two divided doses during the first 24 hours of treatment (table 2). One hundred fifteen men were given 1.64 gm. of quinine (2 gm. of quinine sulfate) in six divided doses daily, concurrently with varying doses of primaquine. Primaquine was given alone to 220 men. Forty-three received four times the maximum therapeutic dose for 14 days and 7 men received eight times that dose for 5 to 14 days, either alone or concurrently with other drugs. One hundred eighteen men received the following potential antimalarial agents concurrently with varying doses of primaquine: methylene blue, nicotinamide, thionine, Bindschedler's green, toluidine blue, theobromine, aminophylline, ephedrine sulfate, chloramphenicol, or daraprim® (2,4-diamino-5-*p*-chlorophenyl-6-ethylpyrimidine).[8]

PROCEDURES

Drug Administration for 14 Days.—Hemoglobin and methemoglobin determinations[9] were made on all men before they received any drug. During treatment of clinical malaria these determinations were usually made every other day until the last 5 days, when they were performed daily. White blood cell counts were done routinely every other day with differential counts every fourth day; both were checked daily if significant variation from control values occurred. Daily urinalyses were performed on subjects treated during clinical attacks of malaria or whenever toxicity was anticipated. During interim therapy, hemoglobin and methemoglobin levels and white blood cell counts were usually done on the first, seventh, tenth, and fourteenth days of drug administration.

Plasma concentrations of primaquine and pamaquine were determined every other day by the method of Brodie, Undenfriend, and Taggart,[10] which measures only the heptane extractable, diazotized fraction of the drug.

Determinations of direct and indirect serum bilirubin,[11] 30-minute sulfobromophthalein (bromsulphalein®) retention,[12] thymol turbidity,[13] and total plasma proteins[14] were performed on 57 subjects. Control tests were made prior to drug administration and were repeated on the 3rd, 7th, and 14th days.

Weekly and Semiweekly Drug Administration.—Hemoglobin estimations and red and white blood cell counts were performed every other week in the groups receiving chloroquine concurrently with primaquine semiweekly or weekly for 4, 14, and 52 weeks.

EVALUATION OF TOXIC MANIFESTATIONS

Malaria produces anemia, abnormalities in white blood cell counts, and symptoms that may be confused with toxic manifestations of a drug. Consequently, evaluation of toxicity was begun following elimination of the febrile attack. The validity of this method of interpretation of toxic symptoms is supported by the fact that the toxicity of primaquine, when given in the absence of clinical malaria, seldom becomes apparent for three or four days except at extremely high doses (0.12 and 0.24 gm.).

Detailed results are reported only for groups receiving primaquine or pamaquine alone and concurrently with quinine or chloroquine for two weeks. Toxicity observed during shorter or unusual regimens is discussed only when results contradict or modify the conclusions drawn from the standard programs.

TOXICITY AT THERAPEUTIC DOSES

Fifteen Milligrams (Table 3).—Doses of 15 mg. or less produced abdominal symptoms of no greater incidence or severity than those encountered with a placebo. Methemoglobin levels did not rise above 7.8% of the total hemoglobin. One of 67 subjects (1.5%) lost 1.3 gm. per 100 cc. of hemoglobin; the variation in hemoglobin was within ± 1 gm. per 100 cc. in the remaining volunteers. Four subjects (5.9%) had leukocytosis ranging from 11,500 to 13,700 per cubic millimeter. Leukopenia did not occur.

Twenty-Two and One-Half Milligrams.—Seven of 57 subjects (12.3%) had mild to moderate abdominal symptoms during administration of 22.5 mg. of primaquine. No hemoglobin loss exceeded 1 gm. per 100 cc. Twelve volunteers (21%) manifested leukocytosis from 12,100 to 16,400 per cubic millimeter. Leukopenia was not observed.

Thirty Milligrams.—Twenty-two of 214 persons (10.3%) reported mild to moderate abdominal cramps, including six who also complained of epigastric distress which was relieved by antacids. Thirty-two persons (14.9%) lost up to 2 gm. per 100 cc. of hemoglobin. Leukocytosis of 10,000 to 17,000 per cubic millimeter occurred in eight subjects (3.8%). Leukopenia did not occur.

TOXICITY AT HIGH DOSES

Sixty Milligrams (Table 3).—Five of seven volunteers receiving daily doses of 60 mg. during clinical attacks of malaria experienced abdominal symptoms. Complaints ranged from mild and transient to moderate and repeated, or severe and persistent, abdominal cramps. Other abdominal symptoms were anorexia, nausea, occasional vomiting, and mild burning epigastric distress. Cyanosis caused by methemoglobinemia was present in the three subjects receiving primaquine alone. The subjects given quinine concurrently with primaquine did not become cyanotic. One volunteer had a leukocytosis of 13,500 per cubic millimeter. Hemoglobin loss or leukopenia was not observed.

One Hundred Twenty Milligrams. — Abdominal symptoms were present in all volunteers receiving primaquine alone or in combination with quinine. Symptoms were so severe in one man receiving quinine concurrently that it was necessary to discontinue the drugs. The five men receiving only primaquine had methemoglobinemia severe enough to produce cyanosis, while only two of six volunteers receiving quinine concurrently with primaquine appeared cyanotic. Hemoglobin variation was within ± 1 gm. per 100 cc. of the control values in the men receiving primaquine alone. Two of the five men receiving quinine concurrently with primaquine lost between 1.1 and 2 gm. per 100 cc. of hemoglobin. Two cases of leukopenia were observed. Agranulocytosis was not encountered.

Two Hundred Forty Milligrams.—Daily doses of 240 mg. further accentuated abdominal symptoms. This group has not been expanded since the preliminary report of Edgcomb and coworkers[4] who discussed in detail the toxic manifestations.

EFFECT OF CONCURRENT ADMINISTRATION OF OTHER DRUGS

Quinine.—Within the therapeutic dosage range, concurrent administration of quinine with primaquine did not increase abdominal symptoms beyond the amount clearly attributable to cinchonism. At higher dosages of primaquine, however, the concurrent administration of quinine increased the subjective manifestations of toxicity.

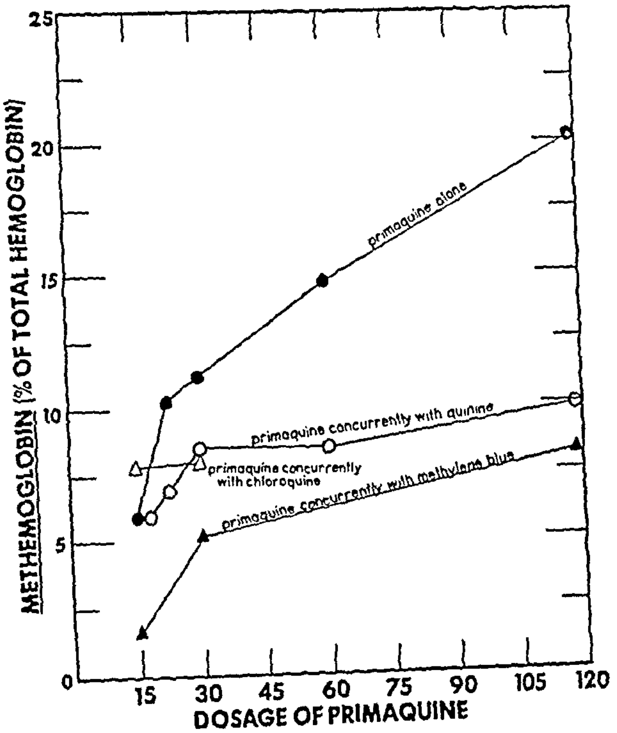
Above 15 mg. of primaquine, methemoglobin concentrations were lower when quinine was administered concurrently. This effect of quinine became more apparent as the therapeutic range of primaquine was exceeded (fig. 1).

Within the therapeutic range, the average concentration of primaquine in the plasma was unaffected by concurrent administration of quinine. In the small number of patients treated at very high dosages, the average plasma concentration of primaquine was approximately 50% lower in the group receiving quinine concurrently.

Chloroquine.—In the therapeutic range, chloroquine did not increase the toxicity of primaquine. The symptoms and toxic manifestations after the first two days were the same as those encountered during drug administration to well persons.

Miscellaneous Drugs.—Methylene blue, nicotinamide, thionine, Bindschedler's green, and toluidine blue were tested at widely varying doses as concurrent drugs. Methemoglobinemia during their administration in sufficiently high dosages was lower than when primaquine was administered alone. Methylene blue appeared to be the most effective in reducing methemoglobinemia (figure). Other toxic manifestations of primaquine were not increased by the concurrent administration of these drugs.



Effect of concurrent administration of quinine, chloroquine, and methylene blue on the methemoglobin concentration of white subjects treated with primaquine at various dosages for two weeks.

Ephedrine, theobromine, and aminophylline were used concurrently with primaquine following the observation that intravenous aminophylline relieved abdominal cramps for a short time. Each of these drugs, when administered orally, reduced the incidence and severity of symptoms at the higher dosages of primaquine.

Three subjects were treated with 25 mg. of daraprim® concurrently with primaquine at therapeutic doses for 14 days. No adverse reactions were noted but the series was too small to warrant further conclusions.

TOXICITY OBSERVED DURING LONG-TERM PRIMAQUINE-CHLOROQUINE ADMINISTRATION

To test chronic toxicity of primaquine given concurrently with chloroquine, two groups of 20 normal white men were studied for 52 weeks. The first group received 30 mg. of primaquine plus 300 mg. of chloroquine in a single dose once weekly, simulating the current use of chloroquine in field suppression. The second group received 30 mg. of primaquine and 150 mg. of chloroquine simultaneously in a single dose twice weekly. Abnormalities in the red and white blood cell counts were not observed. One volunteer in each group requested to be withdrawn from the study after six months. Their symptoms were mild, transient abdominal cramps, epigastric distress, and anorexia for one to three days following ingestion of each dose of drug. Symptoms began after the fourth month of participation in the program. None of the other volunteers consistently complained of untoward effects.

An additional 10 volunteers were bitten by infected mosquitoes. On the day following infection, these men began to take single weekly doses of 30 mg. of primaquine concurrently with 300 mg. of chloroquine for a total of 14 weeks. Drug was well tolerated by all.

MISCELLANEOUS OBSERVATIONS

Gastric Secretion.—The effect of primaquine on gastric acidity was studied because the epigastric distress associated with the ingestion of primaquine was relieved by food and, in some respects, was similar to that encountered in patients suffering from peptic ulcer. A series of nocturnal hourly gastric aspirations were done as a control in six normal men, and then identical aspirations were continued during administration of single doses of 30 or 60 mg. of primaquine daily for seven days. Variations of free or total acidity were within the limits of control observations.

Liver Function.—Evidence of liver damage was not obtained in liver function studies performed on 57 men receiving 15, 22.5, 30, and 120 mg. of primaquine alone or concurrently with quinine or chloroquine. Three patients hospitalized with infectious hepatitis were given 30 mg. of primaquine for 10, 14, and 18 days. All patients improved; primaquine did not appear to affect the clinical course.

Comparison of Toxicity of Primaquine Given in Single and Divided Dosages Daily.—No difference could be distinguished between the toxic manifestations of primaquine at therapeutic doses administered once a day and the same total dosage administered in three or six equal parts. Abdominal symptoms were of greater incidence and severity when primaquine was administered in single daily doses of more than 30 mg. than they were when the dose was divided. It was impossible to administer single doses of 120 mg. because of the severity of the gastrointestinal symptoms.

Effect of Meals.—The ingestion of primaquine at meal time alleviated abdominal distress even in subjects receiving high dosages.

COMPARISON OF THE RELATIVE TOXICITY OF PAMAQUINE AND PRIMAQUINE

The greater curative effect of primaquine compared to that of pamaquine logically led to a more intensive study at lower doses of the former and higher doses of the latter drug. This discrepancy prevented precise evaluation of their relative toxicity where differences between the two drugs were either not great or not consistent at all dosages.

When primaquine or pamaquine was administered alone or concurrently with quinine the abdominal symptoms were of approximately the same order of magnitude and incidence for both drugs at 30 mg. per day or less. It was not necessary to discontinue drug administration to any subject receiving primaquine in doses below 120 mg., whereas, three subjects receiving 63 mg. of pamaquine daily could not complete the course (tables 3 and 4).

Abnormal laboratory findings after primaquine was administered differed from those encountered during administration of pamaquine as follows: (1) Methemoglobinemia at all dosages was greater with primaquine than with pamaquine. Quinine did not diminish the methemoglobinemia produced by pamaquine. (2) Plasma primaquine concentrations were lower than plasma concentrations of pamaquine at similar dosage schedules. (3) The hemolytic effect of primaquine seemed to be slightly less than that of pamaquine. Two men receiving 15 mg., and four receiving 63 mg. of pamaquine concurrently with quinine lost between 2 and 3 gm. per 100 cc. of hemoglobin. This degree of hemoglobin loss was not observed in any person receiving primaquine at any dose, alone or with a suppressive drug, but some of the groups studied were small. (4) Abnormalities in the white blood cell count occurred less frequently during the administration of primaquine.

DISCUSSION

Toxic symptoms and abnormal laboratory findings resulting from primaquine may be divided into two groups: first, those that are not dangerous but may be annoying; second, those that may constitute a serious threat to life, examples of which are severe neutropenia and acute hemolytic crisis.

The toxic symptoms observed in this study were anorexia, nausea, epigastric distress, abdominal cramps, and occasionally, vomiting, vague chest pain, and weakness. However, symptoms were not present at 15 mg., and symptoms at 30 mg. were mild. At high dosages, weakness was common. In dosages of less than 120 mg. per day, the cramps were not severe enough to warrant discontinuation of drug in any case.

In some subjects, particularly those with mild abdominal cramps, symptoms disappeared after the first week of treatment, while in other persons with more severe cramps, the symptoms increased during the two weeks of drug administration and continued a few days after treatment. Rarely, symptoms of anorexia and mild abdominal cramps persisted up to two weeks after completion of treatment.

* Although anorexia was the most common symptom, abdominal cramps most accurately reflected the severity and therefore were chosen for quantitative evaluation, as follows: 0 = no symptoms; 1+ = mild, transient abdominal cramps; 2+ = moderate, repeated abdominal cramps; 3+ = severe, persistent abdominal cramps; 4+ = intolerably severe abdominal cramps.

† The methemoglobin values tabulated are the average of the last five days of drug administration. The mean methemoglobin concentration of 196 normal subjects was 1.8% of the total hemoglobin; standard deviation was 1.10 and the standard error of the mean 0.08.

‡ The incidence of leukocytosis during drug administration was probably lower than that expressed in the table because all cases except those unequivocally caused by acute intercurrent infection have been included.

† The methemoglobin values tabulated are the average of the last five days of drug administration. The mean methemoglobin concentration of 196 normal subjects was 1.8% of the total hemoglobin; standard deviation was 1.10 and the standard error of the mean 0.08.

‡ The incidence of leukocytosis during drug administration was probably lower than that expressed in the table because all cases except those unequivocally caused by acute intercurrent infection have been included.

In this study, all cases of leukocytosis not clearly caused by intercurrent disease have been included to avoid underestimation of the toxic effect of primaquine. While the frequency of leukocytosis may thereby have been exaggerated, it seems probable that primaquine, at therapeutic dosages, produces a mild stimulation of the bone marrow: at very high doses, depression may result. Though leukocytosis is not dangerous, it may complicate diagnostic problems involving intercurrent infections or the evaluation of acute abdominal pain. Severe neutropenia has not been observed within the therapeutic range in normal persons. However, primaquine should not be given in dosages greater than 15 mg. per day to patients having concurrent diseases that are characterized by bone marrow depression. Brennecke and coworkers[15] have found that arthritic patients exhibiting leukopenia have increased susceptibility to granulocytopenia during primaquine therapy.

---

[15] Brennecke, F. E.; Alving, A. S.; Arnold, J.; Bergenstal, D. M., and DeWind, L. T.: A Preliminary Report on the Effect of Certain 8-aminoquinolines in the Treatment of Rheumatoid Arthritis, J. Lab. and Clin. Med. 38: 795-796 (Nov.) 1951.

Although mild decrease in hemoglobin occasionally has occurred at both high and low doses, severe hemolytic anemia has not been encountered during this study involving 699 white adults receiving primaquine in dosages as high as 240 mg. daily. Severe hemolytic anemia, however, has been observed in Negroes after dosages as low as 30 mg.[16] Because of the potential hemolytic activity of the drug, primaquine should not be administered to persons having complicating diseases characterized by a hemolytic tendency.

Primaquine, at 15 mg. daily, can be administered safely for two weeks without special medical supervision. At 30 mg. daily, primaquine may occasionally produce minor symptoms but can be safely administered to white patients under observation on an out-patient basis. At higher dosage schedules, hospitalization is desirable.

Quinacrine (atabrine®) potentiates the toxicity of pamaquine[17] and pentaquine.[18] Until the effect of quinacrine on primaquine toxicity has been determined, it would seem inadvisable to institute primaquine treatment until several weeks have elapsed following termination of treatment with this suppressive agent. Suppressive agents, at present, should be restricted to quinine and chloroquine, of which the latter is the drug of choice.

A comparison of primaquine and pamaquine can be complete only if the toxicity of the two drugs is correlated with their relative curative action on an equal weight basis; in this respect primaquine is at least four times as effective.

CONCLUSIONS

Primaquine has been administered to 699 adult white subjects in a dosage range of 10 to 240 mg. per day. On the basis of symptoms and laboratory findings it is concluded that, at dosages of 15 mg., primaquine may be safely administered daily for two weeks without special medical supervision. Adult white patients may be followed on an ambulatory basis when receiving doses as high as 30 mg. per day. If it is ever used at higher dosages or administered to patients having diseases known to affect the bone marrow or blood, primaquine should be given only during hospital supervision.

Weekly and semiweekly administration of primaquine for as long as 52 weeks in doses of 30 mg. to 50 subjects did not reveal dangerous toxicity when combined with 0.3 gm. of chloroquine. (All dosages have been expressed in terms of base weight.)

4. TOXICITY OF PRIMAQUINE IN NEGROES

Capt. Robert S. Hockwald, Major John Arnold, and
Capt. Charles B. Clayman, (MC), United States Army
Alf S. Alving, M.D., Chicago

Hemolytic reactions during antimalarial therapy have proved to be a limiting factor in the use of 8-aminoquinolines for the cure of vivax malaria. The most severe type of reaction is clinically identical to blackwater fever, and is characterized by massive, explosive, intravascular hemolysis with hemoglobinemia and hemoglobinuria, which constitutes a medical emergency necessitating immediate transfusions. Acute hemolysis has been observed during the therapeutic use of a number of 8-aminoquinolines, for example, pamaquine,[1] pentaquine,[2] and isopentaquine.[3] The incidence of hemolytic reactions is higher in the dark-skinned races. According to Earle and co-workers,[1] 5 to 10% of Negroes contract acute hemolysis when given 30 mg. or more of pamaquine daily. Only 1% of white subjects studied by him contracted hemolysis which, however, was not acute.

PROCEDURES

Dosage Schedules.—Primaquine[4] 8-(4-amino-1-methylbutylamino)-6-methoxy quinoline, 30 mg. of base daily, was administered orally in single or divided doses to 110 normal male Negro volunteers at Stateville Penitentiary. The men ranged in weight from 130 to 240 lb.; the average being 165 lb. Primaquine was given, alone or concurrently with quinine or chloroquine, for 14 days. This dose is slightly larger than that usually recommended for therapy.

The following four schedules were used:

1. Fifty men were given 30 mg. of primaquine base in a single daily dose for 14 days.
2. Twenty-five men were given 30 mg. of primaquine base daily concurrently with 2 gm. of quinine sulfate (1.64 gm. of base) daily for 14 days (both drugs were administered in six divided doses).
3. Twenty-five men were given 30 mg. of primaquine base in a single daily dose for 14 days concurrently with single doses of chloroquine base, 0.6 gm. on the first day and 0.45 gm. on the second day.
4. Ten men were given 30 mg. of primaquine base for 14 days concurrently with chloroquine base, 0.6 gm. on the first day, 0.45 gm. on the second day, and 0.3 gm. on each of the next 12 days. Both drugs were administered in single daily doses.

The men contracting severe anemia while receiving the 30 mg. dosage subsequently were given 15 mg. of primaquine base orally once daily for 14 days to determine whether the reduced dosage would also produce hemolysis.

Later, the same subjects were given pamaquine orally, 30 mg. of base once daily, to compare the hemolysis with that produced by 30 mg. of primaquine base.

Primaquine, 15 mg. of base, was administered orally, once daily, for 14 days to a second group of 50 normal male Negro volunteers. These men ranged in weight from 127 to 211 lb., the average being 161 lb. The primaquine was given alone or concurrently with chloroquine, 0.6 gm. of base on the first day and 0.45 gm. on the second day. This dose of primaquine has been adopted for routine interim treatment of malaria in Korean veterans.[5]

Special Observations and Laboratory Studies.—Each man was questioned daily to detect unusual symptoms. Methemoglobin and hemoglobin levels were determined daily, three and seven days after drug administration was completed. A white blood cell count was taken initially, every two days while the drug was being given, and three and seven days afterward. Differential white counts were performed initially and thereafter if any significant change in the total white count occurred. A urinalysis was performed before the drug was given, and was later repeated if a marked drop in hemoglobin occurred. The following liver function tests were performed on 32 of the men receiving the 30 mg. dosage: total plasma proteins,[6] 30-minute bromsulphalein retention test,[7] serum bilirubin (direct and indirect),[8] thymol turbidity.[9] Red blood cells from men who developed severe anemia were tested for osmotic fragility and sickling.[10]

Severity of hemolytic reactions was evaluated in the following manner:

No anemia: A variation in hemoglobin from the initial determination of 1 gm. per 100 cc. or less. (Some men had a small rise in hemoglobin during the 14 days.)

Mild anemia: A decrease in hemoglobin of 1.1 to 4 gm. per 100 cc. during 14 days.

Moderate anemia: A decrease in hemoglobin of more than 4 gm. per 100 cc. during 14 days.

Severe anemia: A decrease in hemoglobin which necessitated discontinuation of the drug before 14 days.

Acute intravascular hemolysis: Explosive hemolysis with gross hemoglobinemia and hemoglobinuria, resembling malarial blackwater fever, frequently complicated by acute renal shutdown.

RESULTS

Group Receiving 30 Mg. of Base Daily.—One hundred ten Negroes received 30 mg. of primaquine daily, 105 of whom were able to complete the 14 day schedule. No acute intravascular hemolysis occurred, but mild anemia developed in 17 men. For these 17 men, the mean decrease in hemoglobin was 1.8 gm. per 100 cc. and the standard deviation was ±0.72. Five men contracted severe anemia, which necessitated discontinuation of the drug after four to nine days (fig. 1-5). In the latter group, hemolysis commenced after three to five days. These five men had elevated serum bilirubin and four of them passed dark-colored urine during one or two days before the drug was stopped. The urine of one of the four was burgundy-colored. This man received quinine concurrently with the primaquine (fig. 5). None of the men had red-colored plasma. Red cells from the five men with severe anemia were tested for osmotic fragility and sickling. The results were normal. There were no abnormalities in the other laboratory examinations of any of the 110 men studied, and none of the men had subjective complaints of clinical importance. Leukopenia did not develop. The mean change in methemoglobin concentration was +0.4 gm. per 100 cc. There was no correlation between the degree of methemoglobinemia and hemolysis.

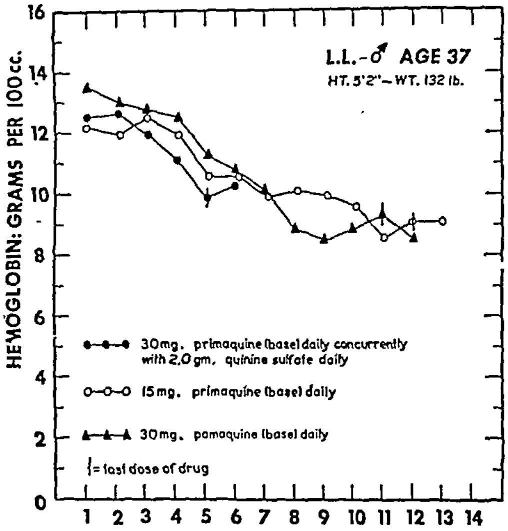

Fig. 1.—Comparison of the hemolytic effects of primaquine and pamaquine in one of five Negroes who had severe anemia. This man had the least severe reaction, and was the only one who never passed grossly discolored urine.

After complete recovery, the five men whose medication had been stopped because of severe anemia were given 15 mg. of base, one-half the original dose of primaquine, daily for 14 days to determine if the reduced dosage would also produce hemolysis. Four of the men contracted mild anemia (fig. 1, 3, 4, 5) more slowly than during the higher dosage of drug. One man did not contract anemia (fig. 2). In a single subject, the drug was discontinued before 14 days, and this was probably done unnecessarily (fig. 1).

Later these five men were given pamaquine, 30 mg. of base in a single dose daily. All five became severely anemic which necessitated discontinuation of the drug (fig. 1-5). The urine of four of the men became dark-colored. In only one subject was the urine benzidine positive; he was the man whose urine had become burgundy-colored while he was on the 30 mg. dosage of primaquine (fig. 5). Methemoglobin formation was slight and leukopenia did not develop. None of the men had red-colored plasma.

All men who had severe anemia recovered spontaneously in 2 to 3 weeks; transfusions were not necessary.

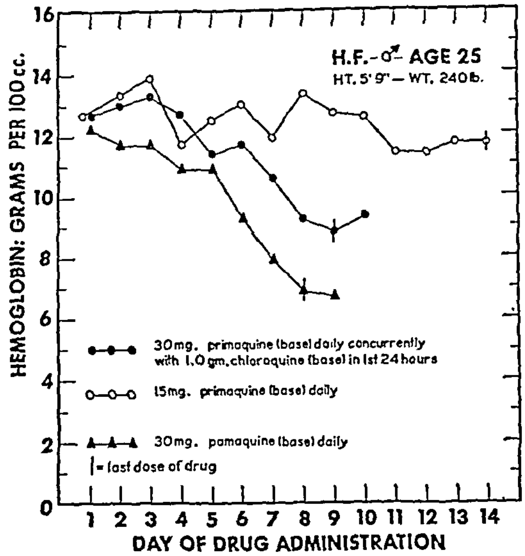

Fig. 2.—Comparison of the hemolytic effects of primaquine and pamaquine in one of five Negroes who had severe anemia. This man had a moderately severe reaction.

Group Receiving 15 Mg. of Base Daily.—In another group of 50 men who received 15 mg. of primaquine base once a day for 14 days, 12 had mild anemia. In these 12 men the mean decrease in hemoglobin was 2 gm. per 100 cc. and the standard deviation was ±0.75. Anemia of any greater degree was not produced. The mean change in methemoglobin concentration was +0.2 gm. per 100 cc. All men were able to complete the 14 day course of drug administration. There were no abnormal findings in the other laboratory examinations of the 50 men studied, and none of the men had complaints of clinical importance.

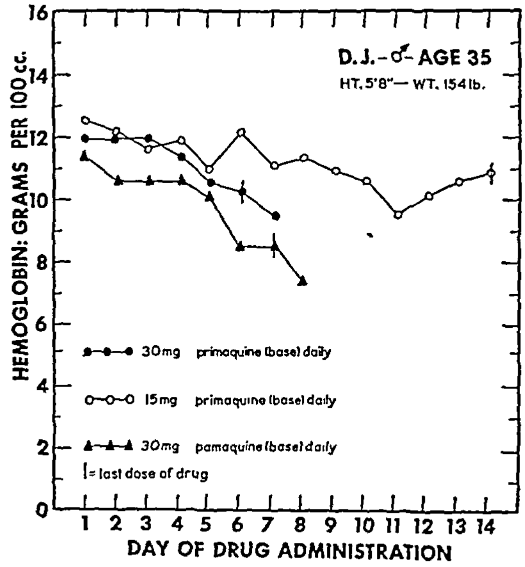

Fig. 3.—Comparison of the hemolytic effects of primaquine and pamaquine in one of five Negroes who had severe anemia. This man had a moderately severe reaction.

DISCUSSION

Primaquine, 30 mg. of base, was administered daily to 110 Negro volunteers at the Illinois State Penitentiary (Stateville).

Severe anemia developed in five of the men, which necessitated discontinuation of the drug before 14 days of administration was completed. The five men were later given pamaquine, 30 mg. of base daily, and anemia of a similar magnitude developed.

Within the group of five volunteers who had severe reactions, it is possible to subdivide the degree of hemolysis further. In the man having the least severe reaction (fig. 1), the urine remained of normal color, although the serum bilirubin was elevated. It was subsequently noted during administration of 15 mg. of primaquine that, after an initial drop, the hemoglobin level became relatively stabilized. In retrospect, it therefore seems that medication was stopped during both periods of primaquine administration before it was urgent. This opinion is further strengthened by the fact that this man was later able to tolerate pamaquine in daily doses of 30 mg. for 11 days, even though the initial rate of fall during administration of pamaquine was almost identical to the decrease when 30 mg. of primaquine had been given to him. The other four men demonstrated more rapid hemolysis (fig. 2-5) and in one of them the reaction nearly approached the severity of blackwater fever (fig. 5). He passed burgundy-colored urine during administration of primaquine and brown urine, which was benzidine positive, during administration of pamaquine.

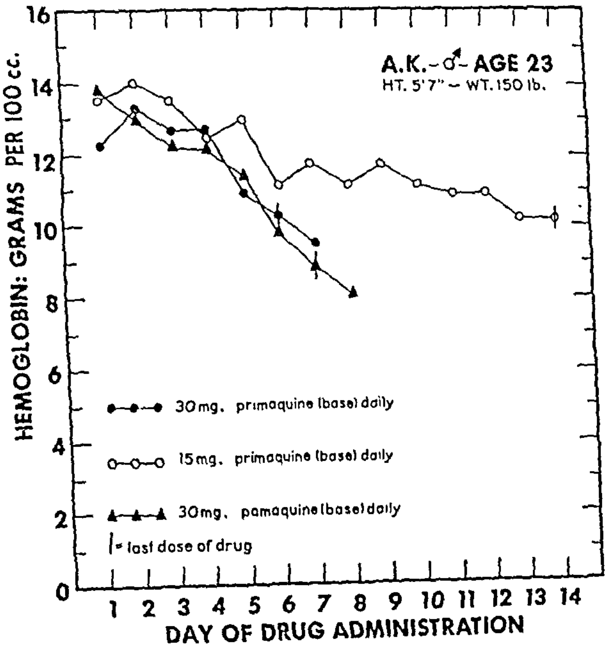

Fig. 4.—Comparison of the hemolytic effects of primaquine and pamaquine in one of five Negroes who had severe anemia. This man had a moderately severe reaction.

Although all of the men had highly colored (yellow to brown) plasma, none had red-colored plasma; and the hemolysis was not explosive as in malarial blackwater fever.

Fifteen milligrams of primaquine base was well tolerated by the five men in whom severe anemia developed and by 50 other Negro volunteers.

These studies, while in progress, served in part as a basis for choosing 15 mg. of primaquine for use in extensive field trials to cure vivax malaria acquired in Korea. The relative safety of administering this dose to Negroes was confirmed by studies on 52 Negroes from the enlisted personnel at Fort Knox, Kentucky, with the cooperation of the United States Army,[11] by studies on 268 Negro veterans from Korea on shipboard between Japan and the United States with the cooperation of the United States Army and Navy and the Military Sea Transport Service,[12] and by studies on 317 Nicaraguan natives who had a mixture of Indian and Negro bloods.[13]

Blake [14] reported that pamaquine and quinine act synergistically to cause increased hemoglobin catabolism. In these studies, 30 mg. of primaquine base was administered alone or with quinine or chloroquine. Each series, however, was too small to determine whether either of these suppressive drugs increased the hemolytic tendency of primaquine.[15]

There was no correlation between methemoglobin formation and hemolysis.

Except for the hemolysis, the men tested showed no evidence of toxicity, and their status during drug administration was similar to that of light-skinned Caucasians given identical doses.

The tendency to hemolytic reactions during administration of primaquine is probably not limited to Negroes, but represents an intrinsic danger to several racial groups. More deeply pigmented persons may have a special predilection to hemolysis during treatment with primaquine, as they have during administration of pamaquine.[1] Taggart [16] has observed a hemolytic reaction of moderate severity in a Caucasian, a Hindu, who received 30 mg. of primaquine base daily concurrently with quinine.

Because of reports that quinacrine increases the toxicity of 8-aminoquinolines,[17] its concurrent use with primaquine should be avoided until more information has been accumulated.

Primaquine should not be used to cure vivax malaria in persons having a concurrent disease characterized by a hemolytic tendency. Thaeler [13] has found, however, that primaquine may be administered safely to mestizoes (persons having a mixture of white, Indian, and Negro blood) in the presence of severe anemia caused by accompanying malnutrition and infestation with intestinal parasites.

CONCLUSIONS

1. Primaquine in doses of 30 mg. of base is *too toxic to be used in Negroes without close medical supervision.* Although subjective complaints were negligible, 5% of 110 volunteer subjects contracted severe and progressive anemia. The anemia was of the same order of magnitude as that developing after th administration of pamaquine, 30 mg. of base daily.

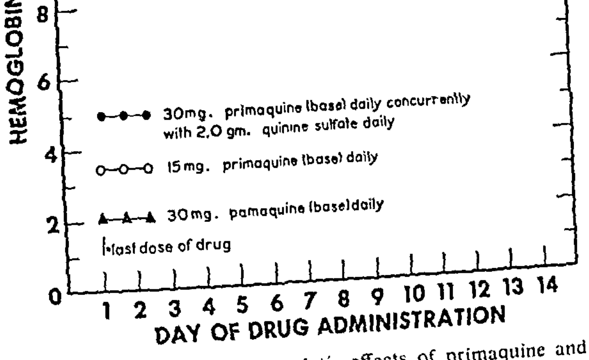

Fig. 5.—Comparison of the hemolytic effects of primaquine and pama quine in one of five Negroes who had severe anemia. This man had th most severe reaction.

2. Studies herein reported indicate that primaquine, 15 mg. c base, can be given safely to adult Negroes for 14 days withou special medical supervision. These findings have been confirme in expanded field studies in military and civilian installation

15. Four of the five men who contracted hemolysis with each program of drug administration, including 30 mg. of pamaquine base alone, were later given pamaquine, 27 mg. of base, concurrently with quinine, 1.64 gm. of base, daily to determine if there was any increased hemolysis. These men had severe hemolysis but the rate was approximately the same as that developing with pamaquine alone. The gastrointestinal complaints were greatly increased when quinine was given, and the hemolysis continued for a longer period after the drug was discontinued.

COUNCIL ON FOODS AND NUTRITION

ACCEPTED FOODS

The following products have been accepted as conforming to the rules of the Council.

JAMES R. WILSON, M.D., *Secretary.*

The Bib Corporation, Lakeland, Fla.

Bib Brand Orange-Apricot Juice for Babies.

Ingredients: Single strength orange juice prepared from Florida oranges specially selected for their natural high ascorbic acid content; fresh apricot puree processed from mature fresh Blenheim—variety apricots and minimal addition of dextrose for standardizing flavor to maintain the brix solids in this product at approximately 20°.

The percentage of apricot and orange used in this product may vary slightly from time to time, depending upon the natural ascorbic acid in the oranges used, so as to maintain a minimum of no less than 30 mg./100 cc. in each 4-ounce can when packed, as well as to maintain uniformity of flavor.

Use.—For use where babies and young children do not take orange juice or in situations where flavor changes might be desirable.

Bib Brand Prune-Orange Juice for Babies.

Ingredients: Prune juice 20 to 21° solids is processed from prune puree produced from Santa Clara variety prunes; Orange juice—single strength prepared from Florida oranges specially selected for their natural high ascorbic acid content, and a minimal addition of dextrose for standardizing flavor to maintain the brix solids in this product at approximately 20°.

The percentage of prune juice and orange juice used in this product may vary slightly from time to time, depending upon the natural ascorbic acid in the oranges used, so as to maintain a minimum of no less than 30 mg./100 cc. of natural ascorbic acid in each 4-ounce can when packed, as well as to maintain uniformity of flavor.

Use.—For use as a valuable supplementary source of natural ascorbic acid for infants and young children when a change from orange juice is desired or prescribed by the doctor for its mild laxative effect.

The Baker Laboratories, Inc., Cleveland, Ohio

Varamel.

Ingredients: A highly nutritious formula base made from grade A (U.S.P.H.S.) cows' milk in which the milk fat has been replaced by coconut oil, destearinated beef fat, and corn oil; with the addition of Vitamin A palmitate, activated 7-dehydrocholesterol, thiamine, niacinamide, and iron ammonium citrate.

Analysis (submitted by manufacturer)—Total solids 20%, moisture 80%, ash 1.2%, fat 5.8%, protein 4.9%, carbohydrate 8.3%, calcium 0.19%, phosphorus 0.15%, iron 0.0016%.

Vitamins	Amounts per Quart*
Vitamin A	2500 U.S.P. Units
Vitamin D	800 U.S.P. Units
Vitamin C	none
Thiamine	0.6 mg.
Niacin	5.0 mg.
Riboflavin	1.2 mg.

*When diluted with an equal part of water.

Calories.—32 per fluid ounce.

Use.—For use in infant feeding.

Winthrop-Stearns, Inc., New York

Essenamine® Powder.

Ingredients: Lactalbumin and carboxymethylcellulose.

Analysis (submitted by manufacturer).—Total solids 96.0%, moisture 4.0%, protein (N x 6.62) 90%, sodium 0.23%, chlorides 0.3%, ash 2.0%.

Calories.—4.0 per gram; 113.4 per ounce.

Use.—For conditions that require an increased intake of protein.

Essenamine® Compound Powder—Vanillin Flavored.

Ingredients: Essenamine® Powder; carob gum, powdered; sucrose, U.S.P. powder; saccharin sodium, U.S.P. powder; vanillin, U.S.P., and coumarin, N.F.

Analysis (submitted by manufacturer).—Total solids 97.0%, moisture 3.0%, ash 1.4%, protein (N x 6.62) 63%, carbohydrate (from cane sugar) 25.0%, sodium 0.16%, chlorides 0.2%.

Calories.—3.5 per gram; 99.2 per ounce.

Use.—For conditions that require an increased intake of protein.

Essenamine® Compound Granules—Vanillin Flavored.

Ingredients: Essenamine® Powder; dextrose, anhydrous; vanillin, U.S.P. and coumarin, N.F.

Analysis (submitted by manufacturer).—Total solids 97.0%, moisture, 3.0%, ash 1.4%, protein (N x 6.62) 63%, carbohydrate (dextrose) 30.0%, sodium 0.16%, chlorides 0.2%.

Calories.—4 per gram; 113.4 per ounce.

Use.—For conditions that require an increased intake of protein.

Beech-Nut Packing Company, Canajoharie, N. Y.

Beech-Nut Junior Creamed Spinach (Chopped).

Ingredients: Spinach, milk, cornstarch, cream, salt, dehydrated onions, and sufficient water for preparation.

Analysis (submitted by manufacturer).—Total solids 9.9%, moisture 90.1%, ash 1.25%, fat 1.69%, protein (N x 6.25) 2.06%, crude fiber 0.44%, carbohydrates other than crude fiber (by difference) 4.1%.

Vitamins and Minerals	Per 100 Gm.
Vitamin A	2,830 I.U.
Thiamine Hydrochloride	0.01 mg.
Riboflavin	0.12 mg.
Nicotinic acid	0.25 mg.
Ascorbic acid	5.7 mg.
Calcium	110 mg.
Phosphorus	44 mg.
Total iron	1.6 mg.
Available iron	1.3 mg.
Copper	0.05 mg.

Calories.—0.45 per gram; 12.8 per ounce.

Use.—For use in the feeding of older infants and young children.

The Cream of Wheat Corporation, Minneapolis.

Zing! Wheat Germ.

Ingredients: Wheat germ and malt syrup.

Analysis (submitted by manufacturer).—Total solids 93.3% to 92.0%, moisture 6.7% to 8.0%, ash 4.2% to 4.8%, fat (ether extract) 10.6% to 13.4%, protein 28.8% to 33.4%.

Vitamins and Minerals	Mg./100 Gm.
Thiamine	2.2—3.4
Riboflavin	0.8
Nicotinic acid	4.4
Pantothenic acid	1.6
Tocopherols	44.0
Phosphorus	1,128
Iron	7.8

Calories.—4.02 per gram; 114 per ounce.

Use.—A food supplement providing the nutrients of wheat germ as indicated above. May be eaten alone as cereal or in combination with other foods.

SOCIALIZED MEDICINE— THE INTERNATIONAL WAY

During the past several years the American medical profession, together with thousands of national, state, and local organizations, representing a cross section of all Americans, have communicated their definite opposition to "socialized medicine" to their state and federal Senators and Representatives. As a result it has become apparent to members of state legislatures and the Congress that compulsory health insurance would not only destroy the present high quality of medical care in this country but that it would endanger the basic American freedoms.

Although the battle against the proponents of political medicine has been won, at least temporarily, in our state legislatures and in the Congress, we are in danger of losing the war through an international approach. In our enthusiasm to espouse such principles as "fundamental human rights," "social progress," and "international peace and security," we have aided and abetted the activities of these forces. Through the wholesale approval of treaties, conventions, and executive agreements, our international representatives have placed not only American medicine but our national sovereignty and our Constitution in jeopardy.

Socialism by treaty is now a greater threat than socialism by domestic legislation, principally because the possibility of political and economic regimentation from an external source is not widely recognized. The public is unaware of the dangers inherent in the treaty-making power because, during the first 150 years of our republic, treaties concerned only the relationship between the United States and other sovereign states. Their attempted use to define the relationship between American citizens and their own government is a recent development—a development, however, which can result in the subtle realization of the socialist's dream of cradle-to-the-grave security.

A recent covenant, entitled "Minimum Standards of Social Security," approved by the International Labor Organization in Geneva in June, 1952, envisions government benefits in nine fields of social security—medical care, sickness benefits, unemployment benefits, old age pensions, employment injury benefits, family allowances, maternity benefits, invalid benefits, and survivors' benefits. While the medical benefits in the covenant are carefully distributed through the document, when they are considered together they constitute "socialized medicine."

Statements on the I. L. O. have appeared recently in THE JOURNAL.[1] In this issue (page 1574) are additional statements that should interest all who are interested in the prevention of the deterioration of medical care through domination by the federal government.

PLACEMENT ASSISTANCE ON RELEASE FROM MILITARY SERVICE

The American Medical Association has recently initiated a new program designed to acquaint physicians being released from active military service with existing medical opportunities, and to assist State Selective Service Medical Advisory Committees in replacing deferred physicians classified in priority 1 under the "Doctor Draft Law."

This program, which was inaugurated by the Council on National Emergency Medical Service with the cooperation of the Department of Defense and the Selective Service System, has the enthusiastic endorsement of the state medical societies and the chairmen of Selective Service Medical Advisory Committees.

The names of physicians to be released from service and other necessary information will be supplied to the Council on National Emergency Medical Service by the offices of the three Surgeon Generals. The Council will communicate with each of these physicians to determine in general their post-service plans, their medical qualifications and specialty, as well as the state in which they prefer to work.

The names of physicians interested in receiving additional information will then be broken down by states and sent to State Selective Service Medical Advisory Committees. While these names are being forwarded primarily as names of potential replacements for deferred priority 1 physicians, further action, if any, with respect to them will depend entirely on the wishes and desires of the advisory committees. This same information will be made available to the state medical societies through the Physicians' Placement Service of the Council on Medical Service in accordance with current procedures.

[1] The World Medical Association, Organization Section, J. A. M. A. **149:** 488 (May 31) 1952. Statement of Dr. Louis H. Bauer Re International Labor Organization and World Medical Association and Resolutions on Amendment to Constitution of the United States (S.J.R. 130), Organization Section, ibid. **149:** 869 (June 28) 1952. Resolutions on International Labor Organization Attempt to Socialize Medicine, ibid., **140:** 938 (July 5) 1952

It is the earnest hope of the Association that the program will be of real assistance to individual physicians and to the state medical societies, and that it will be successful in the satisfactory placement of many physicians upon their release from active duty.

PRIMAQUINE FOR VIVAX MALARIA

Elsewhere in THE JOURNAL (p. 1558) are four reports on malaria and drugs used in control of this disease. These reports provide much practical information for the medical profession and at the same time raise some points not previously appreciated by those not close to this field of investigation. Studies undertaken by the authors of the Council-sponsored reports and some of the results of studies on malaria therapy jointly undertaken by the Medical Research and Development Board of the United States Army, the United States Public Health Service, and the Subcommittee on Malaria of the Committee on Medicine of the National Research Council bring to the physicians of the United States a very practical problem.

When our forces entered Korea in the summer of 1950, chloroquine was administered routinely for the suppression of malaria. Chloroquine is an excellent suppressive drug, but it does not prevent infection with the malaria parasite. In the spring of 1951, when large numbers of troops were returned to the United States and use of suppressive chloroquine was discontinued, attacks of malaria began to occur in Korean returnees and increased in frequency, reaching a peak of more than 600 attacks per week. Acute attacks treated with chloroquine were promptly terminated, but relapses occurred after treatment with the same frequency as in other types of vivax malaria. This prompted the inauguration of a program to evaluate the effectiveness of primaquine, a new 8-aminoquinoline, reported to be superior to pamaquine as a curative agent for vivax malaria. Up to the present time the limited supply of primaquine has necessitated restricting its use to military installations and to other groups included in the studies carried out by the several participant agencies. Because of improved methods of synthesis moderate quantities of the drug will shortly become available. Studies of the toxicity and therapeutic effectiveness of primaquine have been in progress at several military installations. Final evaluation of the therapeutic studies will not be possible until the fall of 1952; however, because the incidence of malaria in Korean returnees is increasing rapidly and because primaquine is now available at military installations, this preliminary summary is presented.

It has been demonstrated that a single dose of 15 mg. of primaquine (base) daily for 14 consecutive days will reduce the relapse rate of Korean malaria to less than 1%. In a control group of more than 450 patients, treated with chloroquine alone, and followed to date, the relapse rate is 30% and is still increasing; in a similar group treated with the same dose of chloroquine, plus primaquine in doses of 15 mg. (base) daily for 14 days, there has been only one relapse.

In a detailed study of toxicity, primaquine was administered to over 300 natives in a jungle area of Nicaragua, in the United States to 1,500 persons at full duty on land, and to 2,700 persons returning from Korea by sea, without evidence of toxicity. In more than 500 patients with malaria who were treated with primaquine in combination with chloroquine, no untoward reactions have been observed. While it is apparent that the toxicity of primaquine in a dosage of 15 mg. (base) per day for 14 days is minimal, it should be pointed out that this agent has all the potential toxicity of pamaquine (hemolytic anemia, bone marrow depression, methemoglobinemia, and abdominal pain), when given at higher doses. However, the maximum tolerated dose of primaquine in white subjects is more than twice the maximum tolerated dose of pamaquine, and the minimum curative dose of primaquine is less than one-fourth that of pamaquine. Like pamaquine, primaquine is more toxic for Negroes than for Caucasians. It has been shown that primaquine, in doses of 30 mg. (base) per day for 14 days, will occasionally produce hemolytic anemia in Negroes. This has not been observed in military installations where dosages of 15 mg. (base) per day have been employed. Data available at this time clearly indicate the following conclusions.

1. The recommended regimen for the treatment of an acute attack is chloroquine, three doses of 0.3 gm. (base) during the first 24 hours, followed by 0.3 gm. (base) daily for two days. Primaquine, in doses of 15 mg. (base) daily, is started simultaneously with chloroquine and continued for 14 consecutive days.

2. Primaquine in doses of 15 mg. (base) per day for 14 days will produce radical cure of Korean vivax malaria, in most persons, by destroying the tissue phases of the parasite. Because primaquine is relatively ineffective in destroying the blood stages of the parasite, it should be used in combination with chloroquine in the treatment of acute attacks of vivax malaria.

3. When primaquine is used at this dosage, no significant toxicity is to be expected in the lightly pigmented races, and it may be administered to the deeply pigmented races under the minimal medical supervision available on troop transport ships. The possibility of a hemolytic reaction should be kept in mind if the patient is deeply pigmented, and the blood hemoglobin concentration determined if extremely dark or brown urine is observed.

ORGANIZATION SECTION

The May 31 issue of THE JOURNAL, *page 489, carried the statement that the World Medical Association had prepared on medical aspects of social security in view of the International Labor Office's proposed international standards for cradle-to-grave social security. The May 31 issue also described the efforts that W. M. A. had made and would make to present these views before this international body with treaty formulation authority.*

The I. L. O. conference was held in June. Despite a vigorous contest over whether the social security standards should be a recommendation or a convention (international treaty) binding on ratifying members, the social security standards were adopted as a convention by the required two-thirds vote, including three of the four American votes.

Membership obligation under the I. L. O. constitution requires that the instrument be submitted by its members, including the United States, to their proper authorities for ratification or rejection and for appropriate legislation. Thus there is a series of questions respecting the international and domestic significance of this new instrument, especially its provisions relating to social security medical programs.

The views of W. M. A. were presented to the Social Security Committee of the I. L. O. The report of that committee to the Plenary Session on the proposed social security standards states:

"The Conference added to the committee as a technical expert without power to vote, Dr. Maystre, a representative of the World Medical Association. Dr. Maystre submitted to the committee a statement of the views of the World Medical Association concerning the provision of health services under social security schemes."

The report also states, "The Committee . . . rejected by a very large majority a proposal to delete Part II altogether . . ." Part II contains the broad medical care social security program. The report further states:

"An employer member submitted a new Article establishing general principles to be observed in the provision of medical care . . . The author explained that this amendment was based on the statement made by the World Medical Association . . . It seemed reasonable that the proposed instrument should contain not only quantitative but also qualitative provisions . . . The Committee, however, by a very large majority . . . did not deem it advisable to do so. . ."

The "employer member" who submitted and fought for both of the above amendments was Leonard J. Calhoun, Washington attorney and social security expert. His observations as to the background of the I. L. O., its actions respecting social security medicine, and the international and domestic significance of the adoption of the new convention are of such interest that these are given below.—ED.

MEDICAL CARE AND THE INTERNATIONAL SOCIAL SECURITY TREATY

Leonard J. Calhoun, Washington, D. C.

In the domestic drive for socialized medicine, defeat of the Wagner-Murray-Dingell bill (the cradle-to-the-grave medical and cash benefits proposal) proved to be only an opening skirmish. The final outcome may be importantly affected by actions taken in far-away Geneva, Switzerland, at the International Labor Conference. This conference has just exercised its authority of formulating international treaties in its adoption of the so-called "Social Security Minimum Standards Convention of 1952."

Minimum Medical Standards.—The principal provisions of the treaty relating to medical care are found in "Part II, Medical Care." The scope of the medical benefits is specified in articles 8, 10 and 12, which read as follows:

"Article 8. The contingencies covered shall include any morbid condition, whatever its cause, and pregnancy and confinement and their consequences."

"Article 10. The benefit shall include at least
- (a) In case of a morbid condition
  - (i) general practitioner care, including domiciliary visiting;
  - (ii) specialist care at hospitals for in-patients and out-patients, and such specialist care as may be available outside hospitals;
  - (iii) the essential pharmaceutical supplies as prescribed by medical or other qualified practitioners; and
  - (iv) hospitalisation where necessary; and
- (b) in case of pregnancy and confinement and their consequences
  - (i) pre-natal, confinement and post-natal care either by medical practitioners or by qualified midwives; and
  - (ii) hospitalisation where necessary."

"Article 12. The benefit . . . shall be throughout the contingency . . . except that, in case of a morbid condition, its duration may be limited to 26 weeks in each case, but . . . provision shall be made to enable the limit to be extended for prescribed diseases recognized as entailing prolonged care."

On first consideration it might seem difficult to formulate any great broadening of the above provisions. The worker block proposed an amendment adding dental care. The American employer representative raised a point of inquiry. The convention was dealing with "minimum standards." If dental care were added, would there be a great difference between the "minimum standards" and the "advanced standards"? This amendment was defeated.

The scope of the minimum standards, covering not only general medical care but eight other programs, was such that the Social Security Committee did not have time to consider the advanced social security standards treaty, and it had to be postponed. The tentative text of the "advanced standards" adds the following to the medical care required under the minimum standards treaty: (1) specialist care without the minimum standards limitation; (2) dental care and supplies; (3) nursing care at home as well as in hospitals; (4) "maintenance in hospitals, convalescent homes, sanatoria or other medical institutions"; (5) "prosthetic appliances, kept in repair, and eyeglasses," in addition to pharmaceuticals; and (6) care of professionals "legally recognized as allied to the medical profession" as well as physicians.

Questions Concerning the I. L. O. Treaty

What is this International Labor Organization? What authority does it have for formulating treaties? Is the United States a member, and did it participate in formulating and vote for adoption of these medical and other social security standards as a treaty? Does this treaty affect us? These are inquiries deserving answers.

Background of I. L. O. Treaty Formulation.—For many decades preceding the formation of I. L. O. in 1919 as an adjunct to the League of Nations, there had been a series of international conferences on labor. These, however, with the exception of an unproductive conference of governments called by Kaiser Wilhelm, had no authority to frame conventions (international treaties). Instead, they were conferences of labor unions and, at times, of employers, who could only pass resolutions and recommendations, which were by and large ignored.

With the establishment of I. L. O. came the authority for framing international labor conventions (treaties). Its unique organization—with 60-odd governments as members but each providing a representative of its employers and a representative of its employees, as well as two government representatives—afforded labor and employer representatives the opportunity of participating in the framing of instruments in the nature of international treaties, binding on all ratifying countries. The United States has been a member since 1934, and reaffirmed its membership after World War II and the broadening of the I. L. O. constitution.

Basis of Social Security Standards Treaty.—Besides what might be classed as normal subject matter for international labor treaties, such as the treatment by countries of seafarers and of non-nationals, matters such as hours of work for women and children have been considered appropriate by conferences preceding I. L. O. and by I. L. O. itself. The general theory has been that treaties were essential if nations were to have humane legislation of this type without suffering the probably catastrophic consequences of loss of foreign markets to competitors with less humane laws.

The present theories supporting the promulgation of documents such as the social security standards in the form of international treaties appear to stem from a very broad base indeed, afforded by the language found in the preamble to the constitution of I. L. O. and the declaration annexed to the constitution. This preamble and declaration are to the effect that "social justice," including, among other things, all-out social security, is essential to the establishment of lasting peace, and that failure of any nation to act is an obstacle hindering other nations. This lays a broad predicate for international treaties governing domestic programs of the ratifying countries.

Chapter I, article I, of the constitution states, "A permanent organization is hereby established for the promotion of the objects set forth in the preamble . . . and in the declaration . . . which is annexed . . ." The declaration annexed states, "The Conference recognizes the solemn obligation of the I. L. O. to further among the nations of the world programs which will achieve: . . . (f) the extension of social security measures to provide a basic income to all in need of such protection and comprehensive medical care." The United States Government, incident to its I. L. O. membership, has ratified this constitution and the annexed declaration.

It is difficult to demonstrate, therefore, that the social security minimum standards treaty is outside the scope of the I. L. O. constitution or that in reaffirming its I. L. O. membership after adoption of the preamble and declaration the United States was not put on notice that a treaty of this type might be promulgated. A point that might have been raised when the amended charter was up for consideration is whether the United States did in fact subscribe to the statements and assumptions of the preamble and the declaration. Certainly this was a pertinent question, particularly with respect to medical care.

I. L. O. Emphasis on Treaties.—While I. L. O. has a much wider field of action that has great potential value, the thrust and drive of some governments and the solid labor block has been in the direction of treaties in achieving I. L. O. purposes. If one subscribes to the philosophy that the broad I. L. O. social security and other objectives can be achieved by national legislation, and only by that process, and that these national programs are essential to preserve peace, in other words, if one subscribes to the interpretation of I. L. O. made by labor and many governments, it must be admitted that there is some logic back of the demands for international treaties dealing with the international standards for state medical care and other social security programs.

Our Philosophy vs. Welfare State Philosophy

There is no question as to the desirability of social justice and of the economic security of the individual. But neither, at least from our viewpoint, is there any question of the paramount desirability of individual freedom—including freedom from dependence of an all-powerful state. Nor do we question the fact that such freedom can be achieved only under what is termed free enterprise. Thus, unless we are in time to surrender to the philosophy back of the new social security treaty, it would seem essential that we spell out and actively press for the philosophy of free enterprise.

That this task is not easy, in view of much current international thinking, is manifest when a sample or so taken from the speeches made in Geneva respecting the new social security standards is considered. Perhaps the statement made at the International Labor Conference by Mr. Leao de Vasconcelos of Brazil might be taken as typifying a good bit of thinking regarding social security by some governments. He stated:

"One of the most important characteristics of the modern world is the constant interest shown in social problems and in social security. The introduction of effective measures of social security and public assistance is considered one of the best means of alleviating misery and of avoiding the emergence of seditious forces.

"We therefore feel it is essential to achieve international understanding in the social field and to establish international standards . . . Now that we are conscious that labour legislation, including that relating to social security and social welfare, will have a very great influence on economic life, sacrifices must be made to enable the workers to enjoy a decent standard of living within the economic framework."

The general attitude of workers in demanding treaties is probably that indicated by Mr. Texier of France:

"To meet human needs is one of the essential purposes of social security . . . It was to give concrete expression to this indispensable concept of social security that . . . the I. L. O. adopted recommendations . . . concerning income security and medical care . . . Either by means of valid legal documents we sanction the principles . . . or we take on ourselves the heavy responsibility of bringing to a halt our progress towards the achievement of social security and greater social justice."

Notwithstanding past experience as to ratifications and the arguments advanced against adoption of the social security standards in the form of a convention (treaty), the workers' monolithic position on social security standards ran true to pattern. A principal answer to all arguments against the form of the instrument was to impugn the motives of those advancing the arguments. This answer was summed up by an American worker representative in the following statement: ". . . employers generally are against conventions because conventions carry with them the obligation to act, to do something, to carry out objectives in support of the workers throughout the world."

United States Government Votes for the Treaty

Under the I. L. O. constitution, for an instrument to be adopted either as a convention (international treaty) or a recommendation, a two-thirds record vote is required. If it fails to secure the necessary vote as a convention, on motion of any member it may be adopted as a recommendation and revised accordingly. Thus, even if a member believes that the instrument sets fair standards, he still has the choice of voting whether the instrument should be advisory to members or mandatory on all ratifying members.

In the Social Security Committee two votes indicated that less than two-thirds wanted a convention. One vote was taken at the beginning of its sessions to determine the basis on which the text would be drafted, the other at the end of its sessions. In both instances the vote in favor of a convention fell substantially short of two-thirds, although the worker representatives voted solidly for a convention. Thus there is every reason to believe that in plenary session the instrument would not have been adopted as a convention except for a shift in position by government delegates who had previously voted against it as a convention.

In the light of these facts it is difficult to evaluate a United States government representative's statement in plenary session, before the final vote: "The United States Government delegation is going to vote for the convention . . . The United States Government supported the amendment to change its form to a recommendation. Nevertheless, while believing that a recommendation would be preferable, we will not withhold our support for a convention since the Conference prefers that form." It would appear obvious that an announced intention of this nature influenced the final adoption of the minimum social security standards in the form of an international treaty.

Whatever may be an administration's social security policies or our nation's current social security programs, there is an important question as to whether instruments like the new social security convention should be ratified. The solemn nature of treaties is recognized in our Constitution. Article VI, Clause 2, provides as follows: ". . . all treaties made, or which shall be made, under authority of the United States, shall be the supreme law of the land; and the judges in every State shall be bound thereby, anything in the constitution or laws of any State to the contrary notwithstanding."

Regardless of legal refinements as to the exact legal situation on ratifying a treaty by virtue of the foregoing provision, it seems obvious that voting in favor of provisions and their adoption as treaties should be matters of great thought and caution by representatives of the United States. In our current social security laws Congress has specifically reserved the right to amend or repeal them. This is obviously inconsistent with a permanent obligation to maintain social security programs meeting international specifications. Being a "good fellow" or "going along with the majority" affords no basis for voting for a convention containing provisions inconsistent with national policy, evidenced by congressional action, or of placing the government in the awkward position of refusing ratification of an instrument that its representatives have helped formulate and voted for as a treaty.

Of course, the fact that our government representatives voted for this treaty does not mean that our social security is automatically changed to include socialized medical care and other benefits in conformity with the provisions of any of its nine programs. Nor does it mean that the Senate will ratify it, or that Congress will pass implementing social security legislation establishing medical care, compensation for sickness, invalidity, maternity, family allowance, or other programs within its purview. Even ratification does not require adherence to more than three programs.

But beyond question, from an international viewpoint, the United States government is in the position of having voted in favor of the adoption of these social security minimum standards and of having voted that these standards shall be in the form of an international treaty. Under our international obligation assumed under the I. L. O. constitution as an I. L. O. member, this document must be considered for ratification and enactment of implementing legislation contemplated. The same situation may again arise in connection with the presently postponed advanced social security standards.

With these considerations in mind, let us examine further some of the major medical care aspects and the basic principles involved and the political maneuvers employed in getting the instrument adopted as a convention.

Ratification on the Basis of Token Programs.—In the case of the United States and other "developed" countries, under the treaty the medical benefits scheme must, at a minimum, cover (*a*) at least half of all employees in the country plus their wives and children; or (*b*) "economically active" persons constituting at least one-fifth of the total population, plus their wives and children; or (*c*) half of the population. Other programs require correspondingly broad coverage.

Obviously a very large percentage of the 60-odd nations belonging to I. L. O. could not possibly provide medical programs of this extent, and would not vote for the instrument as a convention unless they could ratify it. The tentative text had escape clauses, permitting ratification by these nations with little more than token coverage. Medical care, in their cases, need cover only half the "employees in industrial work places employing 20 persons or more, and also their wives and children." In many undeveloped countries such persons would constitute only a negligible proportion of the population.

This "practical" provision has very obvious political advantages. The token program that was permitted for countries like India secures their vote for a convention. They can have the prestige of ratifying an international treaty on social security standards, even though millions of their people may be starving. Without this concession, adoption of the convention desired by labor and some of the governments of "advanced countries" would not have been politically possible.

How Long Is Temporary?—Article 3, the "escape clause" above referred to, applies to any "member whose economy and medical facilities are insufficiently developed"—a substantial majority of I. L. O. voting strength. The theory in the text was that this was a mere temporary provision. Obviously the "escape clause" did not get labor in those countries very far. Amusingly enough, when "temporary" was defined by a solid labor vote and many government votes as not more than 10 years a great deal of furor arose among the governments concerned.

At the plenary session, Mr. Stark, Workers' Advisor of Austria and leader of the worker block, recognized that, if "temporary" remained defined as 10 years, these countries' votes would be lost and there would probably be no convention. Hence he stated, respecting a floor amendment deleting the 10 years limit, "In the interest of making ratification possible, and in the interest of frankness, as far as ratification is concerned, the workers' group has decided, however, to vote in favor of this amendment."

Thus a purely political maneuver, indefensible under I. L. O. principles, insured that I. L. O. minimum social security standards could be adopted as an international convention.

World Medical Association Recommendations

In the May 31 issue of THE JOURNAL, page 488, it was stated with respect to W. M. A. recommendations as follows:

"The only section in the document that may puzzle American physicians is that pertaining to Principle XI, which reads: 'Compulsory health insurance plans should cover only those persons who are unable to make their own arrangements for medical care.' In the United States physicians do not believe that compulsory plans are necessary for anyone. It must be remembered, however, that many countries do have compulsory plans, but the doctors in all countries that are members of the WMA are in agreement that if such plans do exist they should be limited as expressed in the quoted statement."

Section XI might be described as an attempt to limit social security medical care to what is sometimes described as the "medically needy." It is very understandably the position of physicians who are faced by the grim reality of a compulsory medical care program. To the extent that patients are left free to make private arrangements, physicians are free to enter into such arrangements with them.

Great practical and political difficulties attend any effort to have a nation "half slave and half free" medically. The whole thrust and drive of the philosophy of compulsory social security is in opposition to making the source of medical care dependent on the means of the patient. This is regarded as "degrading." Financing is very frequently by special taxes called "contributions" and these "contributions" of higher paid persons may be in part used for the benefit of lower paid persons, just as in our old-age and survivors insurance system. Obviously the cost distribution machinery of such a system is crippled if the higher paid are exempt, and there are political difficulties in connecting "compulsory contributions" for medical care denied some contributors. Obviously section XI would raise a host of side issues to the main issue of "medical freedom."

The "Medical Freedom" Amendment.—Without consultation with the W. M. A. I decided to introduce a specific amendment embodying broad principles that it had advanced. Rightly or wrongly, to avoid issues such as those indicated above, I decided to omit the "medically needy" coverage provision and certain others of its 12 points.

The rejected amendment was as follows:

"Add a new Article 64 bis, as follows:

In the provision of medical care referred to in Parts II and VIII the following general principles shall be observed:

1. There shall be freedom of choice of physician and hospital by the patient except in cases of emergency.
2. There shall be no intervention of a third party between the physician and the patient.
3. There shall be no restriction as to medication or mode of treatment prescribed by the physician except in case of abuse.
4. Physicians shall have the right to participate or refuse to participate in the medical care system and their participation shall not be conditioned on their moving to or from any area or becoming employees of the government or engaging in any special kind of practice.
5. Physicians shall be appropriately represented on administrative and advisory bodies concerned with the provision of the medical care.
6. There shall be no exploitation of the physician or the physician's services."

Action on the Amendment.—This amendment was introduced with the statement that any clarifying amendments were welcome, and it was an amendment designed to secure the adoption or rejection of broad principles and to be discussed on that basis, and not on the basis of minor matters that could be corrected by subamendments. A brief description of some of the discussion is contained in the committee report on the new social security instrument. This statement is as follows:

"An Employers' member submitted a proposal to add a new Article establishing general principles to be observed in the provision of medical care. These included notably free choice of doctor and hospital by the patient; non-intervention of a third party between physician and the patient; freedom of medication and mode of treatment by the physician except in case of abuse; right of the doctor to participate in the service; appropriate representation of physicians in administrative and advisory bodies, and a guarantee that there should be no exploitation of the physician or the physician's services.

"The author explained that this amendment was based on the statement made by the World Medical Association, which represented medical associations in 43 countries and some 700,000 doctors. It seemed reasonable that the proposed instrument should contain not only quantitative but also qualitative provisions; as this had been done in the Medical Care Recommendation, No. 69, adopted in 1944, there seemed to be no reason for not including such an important matter in the instrument under consideration.

"The Committee, however, by a large majority comprising members of all three groups, did not deem it advisable to do so, more particularly in view of the fact that, to many members, the principles formulated in the amendment would not be acceptable without modification. Moreover, this subject would require careful examination and was, in any case, not within the competence of this Committee."

The assigned "reasons" for rejecting the amendment were mere smoke screens. No modifications of the amendment were suggested by anyone opposing it. The matter was fully in the competence of the committee, as evidenced by the fact that a "freedom of doctor" provision was adopted in the revised maternity convention also voted out by the conference this year. The English government representative stated that England could not ratify a convention containing the amendment.

Fundamental Conflicts Between "Social Security" Medicine and Private Medicine

Adoption of the amendment would probably have meant little more than an empty gesture. There are fundamental and probably irreconcilable conflicts between the underlying philosophy and practices of "compulsory health insurance" and the individual freedoms called for in the amendment.

The philosophy of "health insurance" calls for universal coverage of people and medical services. The practical situation is that freedom of a medical practitioner may be akin to the freedom to stop practicing; his position in not participating is that of dependence on persons who have already paid for their medical care who may exercise their "freedom" by coming to him and paying again. Under the philosophy of a compulsory system, the state assumes responsibility to have practitioners and hospitals available for everyone covered. Such a responsibility is inconsistent with any prohibition against coercing physicians to move to places where the state must have them in meeting its obligations.

The medical care is a "benefit," conceptually a matter of right, and its denial, whether because of medical judgment or other cause, is, under specific provisions of the treaty, a matter of administrative or court action and decision. This concept is hardly compatible with the principle of nonintervention of third parties. Being operated by government, the system is by nature subject to politics. What practical meaning would be given the prohibition against exploitation of physicians or physicians' services? If physicians are underpaid—whether on a fee, salary, or per capita basis—and equitable adjustment means raising "contributions" on a hundred times the number of underpaid physicians, the obvious political answer is to "protect" the "contributors."

The foregoing is merely illustrative of a host of fundamental considerations surrounding "social security medicine," however designated and however described. Fundamental considerations of this kind must be used in evaluating such statements respecting medical freedom as that made on the floor of the I. L. O. Conference by an American labor representative:

"Now, speaking solely as an American, I would like to make a few brief remarks on the problem that was raised by the Employers' representative of the United States when he spoke about 'socialised medicine.' He said that as an employer he could not support this social security Convention because one of its branches, medical aid, was socialised medicine. I just want to say that the implication of that remark is that those of us in the United States who are supporting what we call medical assistance, or a national health insurance programme, do not call that socialised medicine—nor is it. The programme advocated in the United States by the trade union movement is one which ensures freedom of choice of doctor, freedom of choice of hospitals, and freedom of choice of medical assistance in any form, and does not in any way interfere with the normal patient-doctor relationship which Mr. Calhoun, the Employers' representative of the United States, has talked about.

"I would like this Conference to know that, as far as the United States is concerned, we do believe in health insurance and we hope that before long, through the strength of our trade union movement and the representatives of our Federal Government who support the national health insurance programme, we will be able to have such a programme."

American medicine must stand ready to answer whether or not we can have the medical utopia indicated by this statement, and its answer must deal clearly and understandably with fundamental facts and principles.

THE INTERNATIONAL LABOR ORGANIZATION—ITS HISTORY, PURPOSE, AND PLANS

This article has been prepared in the office of the Committee on Legislation of the American Medical Association because of the increasing interest of the medical profession in the International Labor Organization.—Ed.

The International Labor Organization, meeting in Geneva in June, 1952, approved a Convention on Minimum Standards of Social Security in nine fields: medical care, sickness benefits, unemployment benefits, old age pensions, employment injury benefits, family allowances, maternity benefits, invalidity benefits, and survivor benefits.

While the medical benefits in the convention are carefully distributed throughout the document, considered together they constitute what is commonly referred to as "socialized medicine." The approval of this convention, with an affirmative vote by the majority of the United States delegates, in the face of a clear-cut repudiation of compulsory health insurance by the American people and their representatives in Congress, is tangible evidence of a determination to provide socialized medicine even in the face of objections by citizen voters.

At the meeting of the House of Delegates of the American Medical Association in June of this year a resolution was adopted that, in part, advocated "an amendment to the Constitution of the United States which will provide that no Treaty or Executive Agreement shall be made which conflicts with any provision of the Constitution or which operates, or may operate, to regulate any of the purely domestic affairs of the United States." Every physician should acquaint himself with the details of the organization, the history, and the program of the United Nations and the I. L. O. The purpose of this article is to present, in detail, pertinent facts concerning the I. L. O. and to discuss the treaty as an instrument of legislation.

History of the I. L. O.

The charter that brought the United Nations into being on Oct. 24, 1945, provided for a General Assembly, a Security Council, an Economic and Social Council, an International Court of Justice, a Trusteeship Council, and a Secretariat. In addition, more than a score of commissions and specialized agencies were created. The I. L. O. was the first such agency with which the United Nations established such a relationship. This relationship was agreed on by the I. L. O.'s general conference and by the U. N.'s General Assembly in 1946.

Simply stated, the I. L. O. is an association of nations. It was established on April 11, 1919, by the adoption of Part XIII of the Treaty of Versailles, and during the period between World War I and World War II was affiliated with the League of Nations. The charter members were the original members of the League of Nations. Countries joining the League later automatically became members of the I. L. O., whereas nonmembers of the League could be admitted by order of the International

Labor Conference. The United States, although a signatory of the League Covenant, was not a charter member and did not join until 1934.

The I. L. O.'s present constitution recognizes as members those governments that were members on Nov. 1, 1945. It also provides that any member of the United Nations can become a member of the I. L. O. simply by accepting the obligations of membership. Countries that are not U. N. members must, on the other hand, file applications, which have to be approved by the general conference. Today the membership numbers 65 countries. Twenty-two are European, 20 are American, 19 are in the Asian and Far Eastern region, and 4 are African.

Purposes

The Commission on Labor Legislation, which drafted the original constitution of the I. L. O., was composed of representatives of the United States, Great Britain, France, Italy, Japan, Belgium, Czechoslovakia, Cuba, and Poland. Samuel Gompers, President of the American Federation of Labor, was chairman of that commission, and Arthur Fontaine of France, who later was to preside for 10 years over the I. L. O.'s governing body, was its general secretary. Its assistant general secretary was H. B. Butler, who subsequently became director of the International Labor Office.

The commission was assigned the task of inquiring "into conditions of employment from the international aspect, and to consider the international means necessary to secure common action on matters affecting conditions of employment, and to recommend the form of a permanent agency to continue such enquiry and consideration. . . ."

One of the first basic decisions to be made concerned the powers that the new organization should have. It is indeed interesting to note that one suggestion was that the new body be given the right to adopt legislation that would automatically become binding on all the member countries. This suggestion, which would have given to an international agency the power to legislate for member governments in matters vitally affecting their domestic economy, was rejected. It was agreed then, and apparently needs to be reemphasized now, that such a plan would result in an invasion of national sovereignty.

It was finally agreed that the organization would draft conventions similar to treaties. These would not automatically become binding on the member countries, but the members would be required to consider accepting or ratifying them. It was agreed that once a country ratified a convention it must give effect to it and submit reports on the way in which it was doing so.

When the general conference of the I. L. O. met at Philadelphia in 1944, a redefinition of the organization's aims and purposes was agreed on. In addition to spelling out the responsibility of the I. L. O. to examine and consider international economic policies and measures, the statement set forth a number of specific objectives. It declared that it shall be a permanent obligation of the I. L. O. to further among the member nations the achievement of the following 10 propositions.

(1) full employment and raising of standards of living; (2) the employment of workers in the occupations in which they can give the fullest measure of their skill and attainments and make their greatest contribution to the common well-being; (3) the provision of facilities for training and the transfer of labor, including migration for employment and settlement; (4) policies in regard to wages and earnings, hours and other conditions of work, and a minimum living wage to all employed and in need of such protection; (5) the effective recognition of the right of collective bargaining, the cooperation of management and labor in the continuous improvement of productive efficiency, and the collaboration of workers and employers in social and economic measures; (6) the extension of social security measures to provide a basic income to all in need of such protection and *comprehensive medical care*; (7) adequate *protection for the life and health of workers* in all occupations; (8) provision for *child welfare and maternity protection;* (9) the provision of adequate nutrition, housing, and facilities for recreation and culture; and (10) the assurance of equality of educational and vocational opportunity. (Emphasis added in 6, 7, and 8 above.)

Organization

The I. L. O. has three basic parts—the general conference, which is also called the International Labor Conference; the governing body, and the International Labor Office. The general conference, which is called together once a year by the governing body, has the task of drafting the International Minimum Social and Labor Standards that later must be considered for ratification by the member countries. Every three years the conference is the scene of the election of members of the governing body. Each year it adopts a budget to finance the organization's work in the succeeding year. It also considers major questions relating to the organization's policy and program. In line with the "tripartite" principle, each of the member countries is represented by four delegates. Two of these represent the government, one represents the workers, and one the employers.

The governing body, or executive council, has authority to act on its own responsibility over a wide range of subjects. Of its 32 members, 16 are government representatives, 8 are workers, and 8 are employers. Eight of the 16 government seats are occupied by representatives of the 8 member countries that are agreed to be of chief industrial importance; the other 8 are elected every three years by the government delegates to the conference.

The governing body elects a chairman from among the government representatives, and two vice-chairmen, one from the workers' group and one from the employers'. It holds meetings three or four times a year. In addition to its responsibilities for the formulation of policies and programs, the governing body controls the work of the International Labor Office, and supervises the activities of a large number of advisory committees and commissions. Among its other responsibilities is the election of the director-general of the office. It also has the job of preparing the agenda of the general conference and making proposals to the conference for the annual budget.

The International Labor Office is composed of the permanent staff, consisting of approximately 600 officials recruited from 50 different nationalities. It is this office that prepares the reports and documents and working papers on which the various organs of the organization base their decisions.

There is also a whole series of advisory committees to assist the organization in its work in particular fields. Finally, there is a committee of experts on the application of conventions and recommendations. It is the job of this body to examine the reports of governments on the way in which they are giving effect to I. L. O. standards.

Procedures

The machinery used to produce an approved I. L. O. convention or recommendation is placed in motion by the submission of a labor "problem" by a member government to the governing body, with the suggestion that it be placed on the next agenda. Following a series of reports by the International Labor Office and technical committees, the text of the recommended convention is submitted to the general conference for a final record vote. In this final vote, if two-thirds of the delegates answer the roll call "yes," the text is approved and another International Labor convention or recommendation is adopted.

Despite the fact that member governments are not required to ratify a convention, the I. L. O. constitution requires the submission of all conventions adopted by such members to their national legislatures within 18 months to be considered for ratification. This policy assures that the convention comes to the attention of the public.

Governments are also required to report to the I. L. O. whether or not a convention has been ratified, what steps they have taken to bring the convention before their legislatures, and "the difficulties which prevent or delay the ratification of such Convention." The committee on the application of conventions and recommendations then prepares a combined report, including a summary of the information that governments have sent in, for submission to the governing body and to the general conference. These documents are referred to a special conference committee composed of government, worker, and employer delegates, which goes over the information that governments have supplied and examines the comments of the committee.

The proceedings of this conference committee are held in public, which tends to insure that the force of public opinion is used to pressure governments into ratifying conventions or implementing those already ratified.

The director-general's report of 1949 points out that: "There is no quick or easy solution to the problem of ratifications, but the exploration of its multiple aspects would be much advanced if the delegates would contribute freely of their views and experience on how implementation of international labor legislation can be furthered, particularly in their own countries."

This statement indicates a failure to recognize and honor the basic purpose and function of the I. L. O. in adopting conventions. While the affirmative vote of the I. L. O. is a prerequisite to submission of a convention to the various countries, this action does not result in international legislation. Under the I. L. O. constitution, it is improper to question the right of any country to refrain from ratification of a convention. Neither the I. L. O. constitution nor any other international agreement establishes such an obligation.

The conventions of the I. L. O. are referred by government delegates of the U. S. A. to the Department of State and the Department of Labor for further study and for a determination as to whether Senatorial consideration is desirable. Only 6 of the 103 conventions framed and adopted by the I. L. O. have been ratified by the United States.

Treaty-Making Powers

While conventions were formerly regarded as international agreements dealing with the less important subject matters of international negotiation, the conventions offered by the I. L. O. have the scope of treaties and are of a distinctively legislative character. It is of extreme importance, therefore, that everyone understand the fact that a treaty, once ratified and in force in the United States, automatically becomes a part of municipal law, a fact that is not generally true in other countries. The country as a whole must realize more than it has in the past that the treaty method of making law lacks the safeguards that exist under its constitutional method of legislating.

Article II, Section 2, of the Constitution of the United States provides: "The President . . . shall have Power, by and with the Advice and Consent of the Senate, to make Treaties, provided two-thirds of the Senators present concur; . . ."

This provision was written at a time when the usual treaty was a contract between sovereignties, a contract that dealt with international affairs—treaties of peace, settlements of war problems, transportation and communication between nations, and similar problems.

The framers of the Constitution were determined that no state should make treaties with foreign powers. It was realized by the founding fathers that in order for stable commercial relations to be established with other countries the Constitution must insure that the federal government could and would carry out its treaties, and thus Article II, Section 2, was enacted in its present form.

James Wilson, one of the members of the Constitutional Convention urged that, if treaties were to have the operation of laws, they should have the sanction of laws. He therefore moved to add the words "and the House of Representatives" after the word Senate. But the view that treaties must be negotiated in secret prevailed, and the supremacy clause was enacted in its present form. The result is that the framing of treaties is a wholly executive function.

While it is true that the two-thirds vote required for ratification by the Senate is sometimes difficult to secure, nevertheless the steps followed in the framing of a treaty neither are within the control of the Senate nor are they publicly recorded in many instances. The fact that a treaty may be submitted either by the United Nations or by a specialized agency presents a procedure essentially different from the negotiation of a treaty between the United States and another country. In this latter instance, the treaty is normally drafted by our own Department of State and presented to another country for consideration.

Of far greater significance than the unorthodox manner in which I. L. O. conventions are prepared is the fact that legislation, the usual mechanism used in deciding domestic issues, is shaped by our own elected officials, and is subject to scrutiny from start to finish. The original bill, the amendments the committee hearings, and the subsequent actions by the House and Senate are all part of the legislative process. Obviously, this is still the proper method to use in considering changes in our domestic law.

It is also worthy of note that in all but a few other countries treaties take effect as municipal or domestic law only when implemented by legislation. Since the United States Constitution makes a treaty the supreme law of the land without regard to implementation, this safeguard does not exist for us. Although states signatory to previous I. L. O. conventions have usually taken the steps necessary to put them in force, the increased use of the treaty for enacting domestic legislation may increase their reluctance to do so and render their advantage in this regard more important.

Summary and Conclusions

It is apparent from the foregoing that the distortion of the treaty power by the I. L. O. could place not only American medicine but national freedom and the Constitution in jeopardy.

Perhaps the greatest danger is that the drafting of treaties by remote commissions not answerable to the American public, the pressure to secure ratification, and the creation of quasi-judicial bodies to hear charges of violations place the administration of important domestic problems in a government of men not of laws. The bureaucratic official is the vital factor in this attempt to secure universality of law throughout countries in which the entire political, religious, and social background is without similarity.

As indicated earlier, representatives from each country to the conferences of the I. L. O. are theoretically chosen as representatives of the government, labor, and management. These conferees meet only for a fraction of each year and have neither the permanent contact nor the experience with general world problems necessary to frame sweeping legislation of the type contained in their conventions. In addition, it can hardly be contended that the delegates for the United States government are true spokesmen for the general public. At the most recent meeting of the I. L. O. in Geneva, and in fact for the past several years, the government delegates appointed by the administration through the Department of Labor have been Sen. James E. Murray of Montana and Assistant Secretary of Labor Philip Kaiser.

The tripartite delegation from the United States, of which these government delegates are a part, operates like a stacked deck. The record of divided votes in the last three international conferences tells this story: On 27 major votes in three years the United States government delegates teamed with the labor delegates 24 times to outvote the delegate representing management.

Although the United States has ratified only six conventions, some of the safeguards that have been suggested to prevent abuse are as follows:

1. The United States Constitution could be amended to provide in substance that:
    (*a*) treaties that conflict with the United States Constitution are invalid.
    (*b*) any treaty that directly and substantially interferes with the domestic legislative jurisdiction is invalid, except when the subject matter presents a truly international problem that requires international action to handle it.
2. The United States could demand that specialized agencies affiliated with the United Nations be prohibited from intervening in the domestic affairs of member governments.
3. The representatives of the United States at I. L. O. meetings could refuse to vote to submit for ratification proposed treaties or conventions that directly and substantially encroach on domestic legislation.

A Senate Joint Resolution was introduced in the Senate on Feb. 7, 1952, by Sen. John W. Bricker of Ohio that would accomplish the first item listed above. This resolution, which was co-sponsored by 58 other Senators, would prevent treaties or executive agreements from nullifying the laws of the United States or the constitutions and laws of the several states and would prevent executive agreements from being used as a substitute for treaties. Although this resolution died with the adjournment of the 82d Congress, it is likely that the same or a similar resolution will be introduced early in the 83d Congress.

MEDICAL NEWS

CALIFORNIA

Radio and Television Speakers' Panel.—The Radio and Television Committee of the San Francisco Medical Society is organizing a panel of physician-members who will be available for radio and television appearances as well as personal addresses before lay audiences. Any member desiring to interpret scientific data for the lay public may join the panel by writing to the society's Radio and Television Committee, consisting of Drs. Anthony B. Diepenbrock, chairman; John J. Miller; and Felix L. Pearl.

COLORADO

Narcotic Violation.—Dr. Leslie Harrison Wade, Denver, pleaded guilty in the United States District Court at Denver to a charge of violation of the federal narcotic law. On May 14 his sentence of one year and one day was suspended, and he was placed on probation for one year.

State Medical Meeting in Estes Park.—The Colorado State Medical Society will hold its annual session Sept. 9-12 at the Stanley Hotel in Estes Park under the presidency of Dr. Harry C. Bryan of Colorado Springs.

On Thursday at 2 p. m. Dr. Louis H. Bauer of Hempstead, N. Y., President of the American Medical Association, will discuss "Recent Developments in A. M. A. Activities." Other guest speakers and their first presentations will include:

Vincent J. O'Conor, Chicago, Neck Obstruction in the Male.
Alexis F. Hartmann, St. Louis, Management of Pediatric Metabolic Emergencies.
Richard B. Cattell, Boston, Surgery of the Gallbladder and Bile Ducts.
Herbert W. Schmidt, Rochester, Minn., Diagnostic Problems Encountered in Chest Diseases.
O. Spurgeon English, Philadelphia, Personality Growth and Development.
Robert M. Zollinger, Columbus, Ohio, Indications for Surgery in Jaundiced Patients.

On Tuesday at 6 p. m. there will be a dinner at which sports trophies won during the afternoon tournaments will be awarded. The dinner is not limited to contestants. The annual banquet, to be held at 7 p. m. Friday, will be followed by a dance at 9:30.

DELAWARE

Dr. Springer Honored.—Dr. Harold L. Springer of Wilmington was honored for his 50th year in medical practice at a testimonial dinner at the Du Pont Country Club. A gold desk clock was presented, and talks in tribute to him were given by Drs. George Wilson and Thomas Klein of Philadelphia. Dr. Springer is a consultant in the surgery division and a former chief surgeon at the Delaware Hospital in Wilmington.

State Medical Meeting.—The Medical Society of Delaware will hold its annual meeting at the Rehoboth Beach Country Club Sept. 8-10 under the presidency of Dr. Ervin L. Stambaugh, Lewes. Guest speakers will include:

Harrison F. Flippin, Philadelphia, The A—B—C of Antimicrobial Therapy.
Paul C. Colonna, Philadelphia, Malunited and Nonunited Femoral Shaft Fractures.
John H. Gibbon Jr., Philadelphia, Surgical Treatment of Carcinoma of the Esophagus.
Theodore R. Fetter, Philadelphia, Management of Urinary Tract Infections.
Reuben Friedman Jr., Philadelphia, Dermatology in Relation to Chiropody.
Anthony Sindoni Jr., Philadelphia, Metabolic Medicine in Relation to Chiropody.
John Lansbury, Philadelphia, The Place of Newer Drugs in Treatment of Arthritis.
Richard W. TeLinde, Baltimore, Endometriosis.
George A. Hahn, Philadelphia, Diagnosis and Management of Uterine Malignancy—A 25 Year Experience.

FLORIDA

Society News.—The newly organized Greater Miami Society of Psychiatry and Neurology has named Dr. James L. Anderson, Miami, temporary chairman and Dr. Paul S. Jarrett, Miami, secretary. Drs. Herman Selinsky and Edward H. Williams, both of Miami, have been appointed as a committee to draw up the constitution and by-laws for the society.

A. M. A. President to Speak in Florida.—The Florida Medical Committee for Better Government will hold its third annual meeting at the George Washington Hotel, Jacksonville, Sept. 6-7. Dr. Louis H. Bauer of Hempstead, N. Y., President of the American Medical Association, will address physicians and their wives at a luncheon meeting at 12:30 p. m. on Sunday. Early reservations are advised.

ILLINOIS

Louis Bothman Fellowship.—The University of Illinois College of Medicine, Chicago, announces the establishment of the Louis Bothman Fellowship in ocular pathology in memory of the late Dr. Bothman, clinical professor of ophthalmology, who was instrumental in developing a laboratory in ocular pathology at the university's Research and Educational Hospitals. The university has received a grant of $5,000 from the Louis Bothman Memorial Fund, Inc., of Phi Delta Epsilon fraternity in support of the fellowship.

Tuberculosis X-Ray Program.—The executive secretary of the Tuberculosis Institute of Chicago and Cook County announces that signs suggestive of tuberculosis were found in about 3 of every 200 persons undergoing the 1952 free chest x-ray examinations in the Chicago area. "The cases have been found," he said, "in time to offer the victim a good chance of recovery and to stop the spread of the infection to others."

A recent study by the institute indicates that the cost of tuberculosis to the community averages more than $15,000 for each case not found until the disease is advanced. The cost includes treatment and aid to the patient's family, if necessary. The x-ray program is being carried out by the institute, the Municipal Tuberculosis Sanitarium, and the Suburban Cook County Tuberculosis Sanitarium District.

Chicago

Pediatric Society Golf Tournament.—The first annual Chicago Pediatric Society golf tournament will be held Sept. 10 at the Northwestern University Course, Lake Street, west of Eden Highway, Wilmette. The fee for golf and dinner is $8, for dinner only, $5.

Annual Conference at Maternity Hospital.—The annual Televised Postgraduate Conference in Obstetrics and Gynecology will be held at Lewis Memorial Maternity Hospital, Sept. 15-19, under the auspices of the department of obstetrics and gynecology, Stritch School of Medicine of Loyola University. Television screens will be placed throughout the hospital to assure clear viewing and listening in connection with the obstetrical procedures, demonstrations, and gynecologic surgery that form the program. There will be no registration fee.

MINNESOTA

Northern Minnesota Meeting.—The annual meeting of the Northern Minnesota Medical Association is being held at Crookston Aug. 22-23. The Friday session features a talk by Dr. Harry E. Ungerleider, director of medical research, Equitable Life Assurance Society, New York, on "The Insurance Aspects of Heart Disease." On Saturday a clinico-roentgenologic-pathological conference will be conducted by Dr. Henry G. Moehring of Duluth and his associates.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Southern Minnesota Medical Association.—The annual meeting of the Southern Minnesota Medical Association will be held at Austin Sept. 8. Among the topics to be discussed are migraine, use of compound F (17-hydroxycorticosterone) in treatment of post-traumatic bursitis of the knee and ankle, cutaneous malignancies, urgent surgical conditions in the newborn period, diseases of the thyroid, Friedländer's pneumonia, danger of use of cortisone in acute rheumatic fever and concurrent renal damage, coronary insufficiency, physicians' disagreements in court, and neurosurgical treatment of intractable pain owing to metastatic carcinoma.

NEW YORK

Degree in Physical Therapy Offered.—The University of Buffalo announces the establishment of a program in physical therapy, offering a degree. The program, which will begin with the fall semester in September, will be given under the aegis of the School of Medicine and the Chronic Disease Research Institute. A four year program will lead to a bachelor of science degree with a major in physical therapy. A 12 month course leading to a certificate of proficiency in physical therapy is offered only to students of advanced standing. The program will meet standards established by the Council on Medical Education and Hospitals of the American Medical Association, the American Physical Therapy Association, the American Registry of Physical Therapists, and the New York State Department of Education.

The following persons, who are members of the faculties of other divisions of the university, are among those appointed to the staff of the new program: Dr. Peter A. Casagrande, assistant in orthopedic surgery; Eulalia W. Fabian, chief, speech and hearing therapy; Dr. Robert A. Kaiser, instructor in anatomy; Dr. Heinz Lichtenstein, assistant in psychiatry; Dr. L. Maxwell Lockie, head, department of therapeutics; Julia E. Lockwood, Ph.D., associate professor of physiology; Dr. Henry V. Morelewicz, medical director, program in physical therapy; Lyle W. Phillips, Ph.D., professor of physics; Clarice Schwartz, chief, occupational therapy; John H. Warfel, Ph.D., instructor in anatomy; and Dr. Walter T. Zimdahl, director, Chronic Disease Research Institute.

New York City

Heat Prostrations.—According to the department of health, 83 deaths from heat prostration were reported during June and July. No heat prostration deaths were reported to the department in 1951, and in 1950 five such deaths were reported. Of the 83 persons listed as killed by heat, 43 were male; 72 were aged 50 and over; 3 were under 1 year of age; 1 was 1 year of age; and 7 were in their 40's.

The record heat wave of July raised the general death rate from the expected 8.7 to 10.1 per 1,000 of population. Increase of deaths from cardiovascular-renal diseases and the slight increase in infant mortality were also attributed to the extreme heat. The average cardiovascular-renal disease rate per 100,000 of population from July in the years 1949-1951 was 440; this year it was 538. The expected infant mortality rate was 22.6, but the actual infant mortality rate in July was 24.4.

Personals.—Dr. John J. Thorpe, who has been a member of the medical staff of Standard Oil Company (New Jersey) since 1949, has been named assistant medical director of Esso Standard Oil Company. Dr. Thorpe was formerly resident physician and research assistant in heart disease at New York Post Graduate Hospital, now University Hospital.——Dr. John Daley, formerly of the Esso medical staff, has been advanced to physician at large with Standard Oil Company (New Jersey).——Dr. James Allan Campbell, dean of Albany Medical College, has been appointed a member of the medical board of the New York State Employees' Retirement System, which acts on all accidental death and disability claims filed in behalf of retirement system members. Dr. Campbell formerly was assistant professor of internal medicine at the University of Illinois College of Medicine.——Dr. Max A. Schneider was recently honored by the Buffalo Fire Fighters, Local 282, AFL, who presented him with medical equipment in recognition of his volunteer services to injured persons. Dr. Schneider, who is assistant resident in medicine at Buffalo General Hospital, was recently awarded the Nelson G. Russell Fellowship in Medicine.

OHIO

Cerebral Palsy Center.—A cerebral palsy training center has been established by the Ohio B. P. O. E. at 325 Broad Ave., N. W., Canton. For the present, preschool children up to the age of 8 years are accepted. Dr. Jack W. Millis of Toledo has been appointed medical director.

Chief Surgeon Resigns.—Dr. B. Noland Carter, head of the University of Cincinnati College of Medicine department of surgery, has resigned after 30 years of service in the department. Dr. Carter, who was affiliated with Johns Hopkins University, Baltimore, before coming to the University of Cincinnati, was appointed to the Christian R. Holmes professorship of surgery at the latter in 1946. He is director of surgical service at Cincinnati General and Children's hospitals and consulting surgeon at Dunham Hospital. During World War II Dr. Carter served in the Surgeon General's department and was awarded the Legion of Merit medal. Dr. Carter was recently honored by a testimonial dinner at the Queen City Club and by publication of an editorial entitled "Well Done, Doctor!" in the *Cincinnati Enquirer*, which ended as follows: "Whatever the future holds for him, if it is in line with his past accomplishments we may be very sure that it will be for the greater good of humanity, because Noland Carter is that kind of a doctor and that kind of a man."

PENNSYLVANIA

Clinic Plan Revised.—The Pennsylvania Department of Health has announced the initiation of a new procedure in the administration of its syphilis control facilities. A number of syphilis clinics have been discontinued in conformity with the reduction of infectious syphilis cases during the past five years, attributed to treatment of the disease with penicillin. Dr. Edgar S. Everhart, chief, venereal disease division, announces that a system of appointment clinics, adopted "in order that sparsely inhabited communities may not entirely be deprived of free treatment facilities," has proved successful during a five month trial.

Telephone Talks to Eight Teaching Centers.—With the fall program of the Graduate Education Institute sponsored by the Medical Society of the State of Pennsylvania talks by medical authorities will be piped by telephone from Philadelphia to the eight teaching centers throughout the state. From 1 to 2 p. m. on Oct. 22, about 1,000 general practitioners in all parts of Pennsylvania will gather at the teaching centers to listen to the latest developments in diagnosis and treatment of heart disease through telephone connections and amplified at the various meeting places. The teaching centers for next season's graduate education courses include Erie, Pittsburgh, Johnstown, Harrisburg, Williamsport, Allentown, Wilkes-Barre, and Philadelphia. As in the past five years, the courses are conducted one day a week in each of the centers for five weeks in the fall and five weeks in the spring.

Philadelphia

Appoint Director of Philadelphia Hospital.—Dr. August H. Groeschel, assistant medical director of New York Hospital, has been named director of the Philadelphia General Hospital. Dr. Groeschel previously served as assistant medical director of the Health Insurance Plan of Greater New York. He will assume his duties in Philadelphia about Oct. 1.

TEXAS

New Unit for Polio Patients.—Since July 7 Hermann Hospital, Houston, has made 38 beds in its clinic building available for polio patients. This unit was opened because of the epidemic that has exhausted the regularly assigned polio beds in the city. Nurses especially trained in polio care were recruited for Hermann with the aid of the Red Cross and the National Foundation for Infantile Paralysis, and the ward was air-conditioned by the Harris County Polio Association. During its first two weeks in operation, the new unit at Hermann had received 23 polio patients.

WEST VIRGINIA

Gift to Medical Society.—Dr. Walter E. Vest, Huntington, presented to the West Virginia State Medical Association a bound volume of the transactions of the Medical Society of the State of West Virginia for the years 1867-1874, which he had found at a second-hand book shop in the South, and which probably is the only such volume in existence today.

Society News.—The West Virginia Society of Anesthesiologists has elected Dr. Eldon B. Tucker, Morgantown, president; Dr. Lester D. Norris, Fairmont, vice-president; and Dr. John F. Morris, Huntington, secretary-treasurer (reelected).——The West Virginia Obstetrical and Gynecological Society reelected Dr. Clarence H. Boso, Huntington, president; Dr. Gates J. Wayburn, Huntington, vice-president; and Dr. Angelo J. Villani, Welch, secretary-treasurer.——In the Association of Pathologists of West Virginia, Dr. Milford L. Hobbs, Morgantown, was named president, and Dr. Richard C. Neale, Bluefield, secretary.

WISCONSIN

University News.—Dr. Abraham B. Schwartz, associate clinical professor of pediatrics, has been named acting director of the pediatrics department at Marquette University School of Medicine, Milwaukee, to succeed the late Dr. Francis R. Janney.

Personals.—Dr. Thomas L. Tolan of Milwaukee was reelected president of the American Hearing Society at its annual meeting in Chicago.——Dr. James P. Conway was recently appointed by the Shorewood Board of Health as village health commissioner to succeed Dr. Jerome M. Jekel, who resigned after 18 years in the office.

Marquette-Jackson Clinic Postgraduate Program.—The annual postgraduate clinic presented by the faculty of the Marquette University School of Medicine, Milwaukee, and the staff of the Jackson Clinic, Madison, will be held Sept. 27, the day of the Wisconsin-Marquette football game. Physicians desiring to attend the meeting and luncheon may write to Dr. Arnold S. Jackson, Chairman, 16 S. Henry St., Madison 3, for a reservation card.

Dr. John S. Hirschboeck, dean of Marquette University School of Medicine, will give a preluncheon address. The medical program will include discussions on eye emergencies, traumatic lesions, common obstetric problems, RH factors in the newborn, indications and contraindication for sympathectomy, and allergy in pediatrics.

GENERAL

Speech Symposium.—The National Society for Crippled Children and Adults, the American Psychological Association's divisions of educational psychology and school psychologists, and the American Speech and Hearing Association will be cosponsors of an all day speech institute at the Statler Hotel, Washington, D. C., Aug. 31, preceding the annual convention of the American Psychological Association in Washington, Sept. 1-5.

Cancer Seminar.—The annual cancer seminar sponsored by the Penrose Cancer Hospital, Colorado Springs, Colo., and the American College of Pathologists will be held at the Broadmoor Hotel in Colorado Springs, Sept. 6. Cases will be considered from the standpoint of radiologic diagnosis followed by discussion of the different histopathological diagnoses submitted.

Dr. Leo G. Rigler, chief, department of radiology and physical medicine, University of Minnesota, Minneapolis, and Dr. Lauren V. Ackerman, professor of surgical pathology and of pathology, Washington University School of Medicine, St. Louis, will be the guest speakers.

Infectious Encephalitis.—According to the U. S. Public Health Service, 90 cases of infectious encephalitis have been reported from 14 counties of California, with 88 from 12 valley counties located in known endemic areas. Since June, of a total of 166 reported, 40 cases have been confirmed by laboratory examination; 39 were found to be western equine encephalomyelitis infections, and 1 was a St. Louis type of disease. There have been 19 deaths. The area of the epidemic extends from Bakersfield to Sacramento. The disease is also present among horses in this area. A small outbreak involving both humans and horses has also been found in Colorado.

Dr. Lorenzo L. Parks, Florida State Board of Health, has reported 10 cases of eastern equine encephalitis among horses and mules in four northeast counties of the state. No human cases were reported from this source.

New Polio Booklets.—The Division of Professional Education of the National Foundation for Infantile Paralysis has issued two new booklets, "Management of Poliomyelitis Patients with Respiratory Difficulty" and "Isolation Techniques and Nursing Care in Poliomyelitis." The former, a digest of a larger manual of the same title, which will be available for limited distribution in the fall, contains material on factors controlling pulmonary ventilation; adverse effects of poliomyelitis on respiration; recognition and treatment of breathing difficulties caused by paralysis of the respiratory muscles; recognition and treatment of breathing difficulties caused by loss of ability to swallow; weaning the patient from the tank respirator; and recognition and treatment of breathing difficulty caused by medullary center involvement.

The 20 page booklet on "Isolation Techniques and Nursing Care in Poliomyelitis" was developed to meet the demand of nurses and other professional groups for information on isolation and nursing procedures. These booklets may be obtained from the foundation's headquarters at 120 Broadway, New York 5.

Chicago Society Offers Postgraduate Courses.—The Chicago Medical Society is sponsoring two postgraduate courses this fall: (1) "Cardiovascular and Renal Diseases" (Sept. 29-Oct. 3), with 55 presentations by a faculty of 34; (2) "Diseases of the Gastrointestinal Tract, Liver and Pancreas" (Oct. 6-10), with 56 presentations by a faculty of 32.

During the luncheons there will be a question and answer period. On Wednesday, a clinical pathological conference will be held from 4:15 to 5:15 p. m. On Thursday, Oct. 2, there will be a dinner at 6:30 p. m. at the Drake Hotel, followed by a scientific meeting at 8 p. m., at which Dr. Paul D. White, Boston, will discuss "Our Ignorance About Heart Disease in Days Gone By."

On Wednesday evening, Oct. 8, there will be a dinner followed by a scientific meeting at which Dr. Waltman Walters, Rochester, Minn., will discuss "Present Day Status of the Surgical Treatment of Gastric and Duodenal Ulcer," and Dr. Burrill B. Crohn, New York, "Early Diagnosis of Gastric Malignancy."

Tuition fee is $75 for each course. For information write the Committee on Postgraduate Medical Education, Chicago Medical Society, 86 E. Randolph St., Chicago 1.

Pediatric Residency Fellowships.—The American Academy of Pediatrics announces that eight fellowships for pediatric residents will be available annually for a period of one year, beginning Jan. 1, 1953. Each recipient will receive $1,000. The awards are made possible by Mr. D. Mead Johnson and Mead Johnson & Company. Criteria for the awards will be (1) a letter from the chief of service, indicating that the proposed person has completed, or will have completed, by Jan. 1, 1953, one year of pediatric training credited by the American Board of Pediatrics; that the resident has performed his work ably; and that there is real need for financial assistance; and (2) a letter from the resident requesting the fellowship, stating that he intends to enter pediatric private practice at the conclusion of his second year of training. Consideration will be given to geographic spread of appointments, so that all sections of the country will be represented, and preference will be given to well-qualified but smaller training centers, which perhaps have fewer resources for assisting residents in training than do some of the larger centers. Seven awards will be made in the United States and one in Canada. Research interests and accomplishments and desire to enter academic pediatrics are not criteria for the awards. Applications must be filed before Oct. 1.

Ophthalmology and Otolaryngology Conference.—A postgraduate conference in ophthalmology and otolaryngology will be held Sept. 15-17 at the Hotel Robert E. Lee, Winston-Salem, N. C., sponsored by the North Carolina Eye, Ear, Nose and Throat Society and the South Carolina Society of Ophthalmology and Otolaryngology. Guest speakers and their first presentations are as follows:

John J. Conley, New York, Diagnosis and Treatment of Cancer of the Head and Neck.
Theodore E. Walsh, St. Louis, Treatment of Acute and Chronic Otitis Media.
Frank Turchik, Bridgeport, Conn., Diagnosis of Nasal Obstruction.
Verling K. Hart, Charlotte, N. C., Interesting Benign Tumors of the Tracheobronchial Tree.
Frank W. Newell, Chicago, Fever Therapy in Ocular Disease.
Harold W. Brown, New York, Diagnosis and Treatment, Motor Anomalies, Vertically Acting Muscles.
P. Robb McDonald, Philadelphia, Safety Procedures in Cataract Extraction.
Irving H. Leopold, Philadelphia, Principles and Practical Application of Autonomic Drug Therapy in Ophthalmology.

The social program includes a barbecue at the Old Town Club on Monday at 6 p. m. and a banquet in the ballroom of the Robert E. Lee on Tuesday, preceded by a cocktail party at 6. A fee of $20 will be charged.

Obstetric Seminar in Florida.—An obstetric seminar under the auspices of the maternal welfare committee of the Florida Medical Association and the bureaus of maternal and child health of South Carolina, Georgia, and Florida will be held at the Sheraton Beach Hotel, Daytona Beach, Fla., Sept. 8-10. Speakers will include:

Warren W. Quillian, Coral Gables, Care of the Premature and the Newborn.
R. Gordon Douglas, New York, Bleeding in Pregnancy, Both Early and Late.
Carl P. Huber, Indianapolis, Prolonged Labor with End-Results; Maternal and Fetal Mortality.
William J. Dieckmann, Chicago, Toxemias of Pregnancy.
F. Bayard Carter, Durham, N. C., Management of Obstetric Difficulties.
Edith L. Potter, Chicago, Pulmonary Disturbance in the Newborn.
Fred L. Adair, Maitland, Fla.; Nutrition in Pregnancy.
Clement A. Smith, New York, Care of the Premature and the Newborn.
John Adriani, New Orleans, Anesthesia and Analgesia in Obstetrics.

Tuesday will be devoted to pediatric problems in relation to obstetric management and the newborn. Maternal and fetal mortality surveys in South Carolina, Georgia, and Florida will be discussed by Drs. J. Decherd Guess, Greenville, S. C.; Guy V. Rice, Atlanta, Ga.; Eugene F. McCall, Jacksonville; and John T. Smedley, Miami, Fla.

A. M. A. First Public Relations Institute.—The American Medical Association's first Medical Public Relations Institute will be held Sept. 4 and 5 at the Edgewater Beach Hotel, Chicago. The institute will be a workshop-type conference where public relations personnel, as well as physicians, can get practical information on the day-to-day operations of a medical public relations program. Primarily for lay public relations and employees of state and county medical societies, the institute supplements the annual Medical Public Relations Conference, which will be held Dec. 1, preceding the A. M. A. Clinical Session in Denver. The two day program will be built around five panel discussions: practical ways to increase physician participation in society activities; modernization of the code of ethics to bring about better relations between mass media and the medical profession; development of the best working relationship between the medical profession and the press, radio, and television; tips to the medical profession in working with community groups; and strengthening medical public service activities.

Friday will be devoted to medicine's place in the community. This session will cover the county medical society's place in community affairs, including tips on how to work with voluntary health agencies, other professions, labor, farm groups, schools and the P. T. A., women's clubs, service clubs, and veterans' groups. In the afternoon the institute will break up into roundtable discussions on field service, radio and television programming, newsletter editing, and direct mail techniques.

A special feature of the institute will be a "Project Parade," which will consist of displays of public relations projects of state and county medical societies. These societies have been invited to display pamphlets, printed materials, or photographs of local events. Guests appearing on the program include Mr. Edward Lindsay, Decatur, Ill., editor of the Decatur Newspapers, Inc.; Mr. Jules Herbuveaux, Chicago, manager of television station WNBQ; Mr. Fred R. Jolly, Peoria, Ill., manager of the Community Relations Department, Caterpillar Tractor Co.; Mr. Ben Park, Chicago, president of a radio documentary company; and Mr. Charles R. Jordan, president of a Chicago advertising agency.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

FOREIGN

Congress of World Medicine.—The World Congress of Medicine will be held Oct. 16-18 at Montecatini, Italy, under the presidency of Prof. Pietro Verga of Naples. Topics listed for discussion include "Living Conditions and Health Conditions of Populations," "Repercussions of the War on Physical and Mental Health," and "Duties of Physicians in Relation to These Problems."

Cardiovascular Surgeons.—The first meeting of the European Society of Cardiovascular Surgery (European Section of the International Society of Angiology) will be held at the University House in Strasbourg, France, Oct. 5 and 6. Discussions will be confined to the chronic obliterations of arteries, aneurysm and embolism excepted. Physicians desiring to discuss this subject should submit their names no later than Sept. 1 to Prof. R. Fontaine, Clinique Chirurgicale A, Strasbourg.

Embryologists to Meet in The Netherlands.—A three day symposium on "The Biochemical and Structural Basis of Morphogenesis" will open the sessions of the International Institute of Embryology in Utrecht, The Netherlands, Aug. 27. The meetings will be held in the zoological laboratory of the University, Janskerkhof 3, which will also be the scene of the meetings of the general assembly of the institute Aug. 30 and 31; the latter will be open to nonmembers.

Medical College in India.—At the request of authorities of the Indian government, the World Health Organization has designated a principal for the medical college in Trivandrum, State of Travancore, S. Indian Union, naming Dr. Axel Hojer, who retired in June as director-general of health in Sweden after serving in that post for 17 years. He previously taught at Lund University. In addition to serving as principal of the medical college, which opened a year and a half ago and which WHO has termed one of the best equipped in India, he will lecture on social and preventive medicine and on public health.

Meeting of French Otorhinolaryngologists.—The 50th Congress of the French Society of Oto-Rhino-Laryngology will be held in the Grand Amphitheatre de la Maison de la Chimie, 28 rue Saint Dominique in Paris, Oct. 13-16, under the presidency of Prof. Portmann of Bordeaux.

Occupational diseases in the field of otorhinolaryngology and cancer of piriform sinus (therapeutic indications and results) will be discussed. Surgical sessions will be held in the mornings in various hospitals, and there will be an exhibit of instruments and otorhinolaryngologic specialties. Information may be obtained from Dr. H. Flurin, Secretary General, 19, avenue Mac Mahon, 17^{e}, Paris.

World Federation for Mental Health.—This organization will meet in Brussels Aug. 24-30, under the presidency of Dr. Alfonso Millan of México, D. F. Plenary sessions will be concerned with a report on the WFMH seminar on "Mental Health and Infant Development" recently held at Chichester, England, "Mental Health Problems of Old Age," "Social Case Work," and "Research and Developments in the International Mental Health Field." Groups will meet daily to discuss "Techniques of Mental Hygiene in Schools for Normal and for Abnormal Children"; "Education of the Public in Principles of Mental Health"; "Practical Measures for Dealing with the Mental Health Problems of Refugees and Displaced Persons"; "Techniques of Mental Hygiene in the Industrial Field"; "Formulation of the Unsolved Problems of Mental Hygiene"; and "Public Health and Mental Health."

DEATHS IN OTHER COUNTRIES

Dr. Jules Tinel of Paris, neurologist, died March 4 at the age of 72. Dr. Tinel in 1911 became chief of Déjerine's Clinic. In 1912 he was appointed chief of the pathological laboratory of the clinic for nervous diseases and from 1915 to 1918 was chief of the neurologic center at Mans. Among Dr. Tinel's more important works are "Injuries of the Nerves," "Endocrinologic Clinic," and "The Nervous Vegetative System."——**Dr. Carlos Comba**, Italian pediatrician, died in Florence, Italy, Nov. 4, 1951, at the age of 80. In 1894 he joined the pediatric department of Professor Mya in Florence, where he remained until 1903, when he was appointed professor of pediatrics at Bologna. In 1911, he returned to Florence as professor, remaining in that position until his retirement in 1943. He was one of the founders of La Societa Italiana de Pediatria and its president from 1920 to 1924. He was editor of the *Revista de clinica pediatrica* for many years. Dr. Comba's clinical contributions covered many fields, notably diphtheria, tuberculosis, meningitis, and measles.

MEETINGS

AMERICAN MEDICAL ASSOCIATION PUBLIC RELATIONS INSTITUTE, Edgewater Beach Hotel, Chicago, Sept. 4-5. Mr. Leo E. Brown, 535 N. Dearborn St., Chicago 10, Director.

AMERICAN ACADEMY FOR CEREBRAL PALSY, Durham, N. C., Oct. 2-4. Dr. Meyer A. Perlstein, 4743 North Drake Ave., Chicago 25, Secretary.

AMERICAN ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY, Chicago, Oct. 12-17. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

AMERICAN ASSOCIATION OF BLOOD BANKS, Hotel Schroeder, Milwaukee, Oct. 9-11. Miss Marjorie Saunders, 3500 Gaston Avenue, Dallas 1, Texas, Secretary.

AMERICAN ASSOCIATION OF MEDICAL RECORD LIBRARIANS, Shoreham Hotel, Washington, D. C., Oct. 13-17. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Secretary.

AMERICAN ASSOCIATION OF OBSTETRICIANS, GYNECOLOGISTS AND ABDOMINAL SURGEONS, The Homestead, Hot Springs, Va., Sept. 4-6. Dr. William F. Mengert, 2211 Oak Lawn Ave., Dallas, Texas, Secretary.

AMERICAN CLINICAL AND CLIMATOLOGICAL ASSOCIATION, Elmira, N. Y., Oct. 16-18. Dr. Marshall N. Fulton, 124 Waterman St., Providence 6, R. I., Secretary.

AMERICAN COLLEGE OF SURGEONS,Waldorf-Astoria, New York, Sept. 22-26. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Secretary.

AMERICAN CONGRESS OF PHYSICAL MEDICINE, Roosevelt Hotel, New York, Aug. 25-29. Dr. Frances Baker, One Tilton Ave., San Mateo, Calif., Secretary.

AMERICAN HOSPITAL ASSOCIATION, Philadelphia, Sept. 15-18. Mr. George Bugbee, 18 East Division St., Chicago 10, Executive Director.

AMERICAN MEDICAL WRITERS' ASSOCIATION, Jefferson Hotel, St. Louis, Oct. 1. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

AMERICAN PHYSIOLOGICAL SOCETY, New Orleans, Sept. 4-6. Dr. E. F. Adolph; University of Rochester School of Medicine and Dentistry, Rochester, N. Y., Secretary.

AMERICAN ROENTGEN RAY SOCIETY, Shamrock Hotel, Houston, Texas, Sept. 23-26. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

AMERICAN SOCIETY OF CLINICAL PATHOLOGISTS, Chicago, Oct. 13-17. Dr. Clyde G. Culbertson, 1040 W. Michigan St., Indianapolis, Secretary.

AMERICAN SOCIETY OF MAXILLOFACIAL SURGEONS, Hotel del Coronado, San Diego, Calif., Sept. 10-13. Dr. Casper M. Epsteen, 25 East Washington St., Chicago 2, Secretary.

ANNUAL GULF COAST REGIONAL CONFERENCE ON INDUSTRIAL HEALTH, Rice Hotel, Houston, Tex., Sept. 24-27. Dr. W. H. Hamrick, P. O. Box 2371, Houston, Tex., Chairman.

BIOLOGICAL PHOTOGRAPHIC ASSOCIATION, Hotel New Yorker, New York, Sept. 10-12. Mr. Lloyd E. Varden, Pavelle Color, Inc., 533 W. 57th St., New York 19, Secretary.

COLLEGE OF AMERICAN PATHOLOGISTS, Drake Hotel, Chicago, Oct. 13-17. Dr. M. G. Westmoreland, 203 N. Wabash Ave., Chicago 1, Executive Secretary.

COLORADO STATE MEDICAL SOCIETY, Stanley Hotel, Estes Park, Sept. 9-12. Mr. Harvey T. Sethman, 835 Republic Bldg., Denver 2, Executive Secretary.

CONSTANTINIAN SOCIETY, Lake Placid Club, Lake Placid, N. Y., Oct. 1-4. Dr. C. F. Shook, P. O. Box 1035-36, Toledo 1, Ohio, Secretary.

DELAWARE, MEDICAL SOCIETY OF, Rehoboth, Sept. 8-10. Dr. Andrew M. Gehret, 822 North American Bldg., Wilmington, Secretary.

DISTRICT OF COLUMBIA, MEDICAL SOCIETY OF THE, Hotel Statler, Washington, Sept. 29-Oct. 1. Mr. Theodore Wiprud, 1718 M St. N.W., Washington, Secretary.

GULF COAST CLINICAL SOCIETY, San Carlos Hotel, Pensacola, Fla., Oct. 16-17. Dr. Dale E. York, 21½ E. Wright St., Pensacola, Fla., Secretary.

KANSAS CITY SOUTHWEST CLINICAL SOCIETY, Kansas City, Mo., Oct. 6-9. Dr. Galen M. Tice, 630 Shukert Bldg., Kansas City, Kansas, Secretary.

KENTUCKY STATE MEDICAL ASSOCIATION, Brown Hotel, Louisville, Oct. 7-9. Dr. Bruce Underwood, 620 S. Third St., Louisville 2, Secretary.

MICHIGAN STATE MEDICAL SOCIETY, Book-Cadillac Hotel, Detroit, Sept. 24-26. Dr. L. Fernald Foster, 606 Townsend St., Lansing 15, Secretary.

MISSISSIPPI VALLEY MEDICAL SOCIETY, Jefferson Hotel, St. Louis, Oct. 1-3. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

MONTANA MEDICAL ASSOCIATION, Florence Hotel, Missoula, Sept. 18-21. Mr. L. R. Hegland, 104 North Broadway, Billings, Executive Secretary.

NEUROSURGICAL SOCIETY OF AMERICA, The Cloister, Sea Island, Ga., Sept. 18-20. Dr. C. D. Hawkes, 22 North Manassas St., Memphis 5, Tenn., Secretary.

NEW HAMPSHIRE MEDICAL SOCIETY, Mt. Washington Hotel, Bretton Woods, Sept. 7-9. Dr. Deering G. Smith, 44 Chester St., Nashua, Secretary.

NORTH PACIFIC PEDIATRIC SOCIETY, Challenger Inn, Sun Valley, Idaho, Sept. 19-20. Dr. S. Gorham Babson, 1107 S.W. 13th Ave., Portland 5, Ore., Secretary.

NORTH PACIFIC SOCIETY OF INTERNAL MEDICINE, Sun Valley, Idaho, Sept. 19-20. Dr. Robert L. King, 1115 Terry Ave., Seattle 1, Wash., Secretary.

NORTH TEXAS-SOUTHERN OKLAHOMA FALL CLINICAL CONFERENCE, Wichita Falls, Texas, Sept. 17. Dr. E. Aubrey Cox, Hamilton Bldg., Wichita Falls, Texas, Chairman.

OREGON STATE MEDICAL SOCIETY, Portland, Oct. 8-11. Dr. Robert F. Miller, 833 S.W. 11th Ave., Portland 5, Secretary.

PACIFIC DERMATOLOGIC ASSOCIATION, Palace Hotel, San Francisco, Aug. 29-30. Dr. Ervin H. Epstein, 447 29th St., Oakland, Calif., Secretary.

Pennsylvania, Medical Society of the State of, Bellevue-Stratford Hotel, Philadelphia, Sept. 28-Oct. 2. Dr. Walter F. Donaldson, 500 Penn Ave., Pittsburgh 22, Secretary.

Tri-State Medical Society of Texas, Louisiana and Arkansas, Texarkana, Texas, Oct. 2-3. Dr. Albert M. Hand, 619 Main St., Texarkana, Texas, *Secretary.*

U. S. Chapter, International College of Surgeons, Conrad Hilton Hotel, *Chicago, Sept. 2-5. Dr. Arnold S. Jackson,* 1516 Lake Shore Drive, Chicago, Executive Secretary.

Utah State Medical Association, Salt Lake City, Sept. 4-6. Dr. T. C. Weggeland, 42 S. Fifth East St., Salt Lake City, Secretary.

Vermont State Medical Society, Mt. Washington Hotel, Bretton Woods, N. H., Sept. 7-9. Dr. James P. Hammond, 128 Merchants Row, Rutland, Secretary.

Virginia, Medical Society of, Jefferson Hotel, Richmond, Sept. 28-Oct. 1. Mr. Robert L. Howard, 1105 West Franklin St., Richmond, Executive *Secretary.*

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 13-17. Dr. Bruce Zimmerman, 338 White-Henry-Stuart Bldg., Seattle, *Secretary.*

Wisconsin, State Medical Society of, Hotel Schroeder, Milwaukee, Oct. 6-8. Mr. Charles H. Crownhart, 704 E. Gorham St., Madison, Secretary.

INTERNATIONAL

Aero Medical Association Interim Meeting, Paris, France, Sept. 26-28. Dr. Armand Robert, 2 Rue Marbeuf, Paris 8e, France, Secretary.

American Congress of Industrial Medicine, Rio de Janeiro, Brazil, Sept. 20-28. Prof. Dr. Jose Pedro Reggi, Calle Arenales No. 981 Buenos Aires, Argentina, Director General.

Australasian Medical Congress, Melbourne Victoria, Australia, Aug. 22-30. Dr. C. H. Dickson, Medical Society Hall, 426 Albert St., East Melbourne, Victoria, Australia, General Secretary.

Congress of International Anesthesia Research Society, Virginia Beach, Virginia, U. S. A., Sept. 22-25.

Congress of International Institute of Embryology, University of Utrecht, Zoological Laboratory, Utrecht, Netherlands, Aug. 27-31. Dr. M. W. Woerdeman, Amsterdam, Holland, President.

European Congress of Cardiology. University of London, Bloomsbury, W.C.1, England, Sept. 10-12. Dr. K. Shirley Smith, 35 Wimpole St., *London,* W.1, England, Secretary.

European Society of Cardiovascular Surgery, Strasbourg, France, Oct. 3-4. Sir James Learmonth, Department of Surgery, University New Buildings, Edinburgh 8, Scotland.

Interamerican Cardiological Congress, Buenos Aires, Argentina, Aug. 31-Sept. 7. Dr. Blas Moia, Larrea 1132, Buenos Ajres, Argentina, Secretary-General.

Inter-American Congress of Public Health, Havana, Cuba. Sept. 26-Oct. 1. Pan-American Sanitary Bureau, 1501 New Hampshire Ave. N.W., Washington 6, D. C.

Inter-American Congress of Radiology, Mexico City, Mexico, Nov. 2-8. Dr. Guido Torres Martinez, Marsella No. 11, Mexico, D.F., Secretary-General.

International Congress of Anthropology and Ethnology, Vienna, Austria, Sept. 1-8. For information write: Secretaries, Royal Anthropological Institute, 52 Upper Bedford Place, London, W.C.1, England.

International Congress on Diseases of the Chest, Rio de Janeiro, Brazil, Aug. 24-30. Mr. Murray Kornfeld, 112 East Chestnut St., Chicago 11, Illinois, Executive Secretary.

International Congress of Haematology, Mar del Plata, Argentina, Sept. 21-26. Dr. Carlos Reussi, *Anchorena 1710,* Buenos Aires, Argentina, Secretary.

International Congress of the History of Medicine, Nice-Cannes, France, and Monaco, Sept. 8-14. Dr. F. A. Sondervorst, 124 Avenue des Allies, Louvain, Belgium, Secretary-General.

International Congress on Hydatid Disease, Santiago, Chile, Nov. 21-24. Organizing Committee, P. O. Box 9183, Santiago, Chile.

International Congress of Internal Medicine, Friends House, London, N.W.1, *Eng. Sept. 15-18.* Sir Harold Boldero, 12 Pall Mall East, London, S.W.1, England, Secretary.

International Congress of Medical Press, Venice, Italy, Oct. 4-5. Dr. Bruno de Biasio, S. Marco 4646, Venice, Italy, *Secretary.*

International Congress on Medical Records, London, England, Sept. 7-12. Miss Gwen Perkins, 120 C Street S.E., Washington, D. C., Chairman.

International Congress of Military Medicine and Pharmacy, Montevideo, Uruguay, March 1-7, 1953. Dirreccion General del *Servico de Sanitad Militar, 8 de Octubre y Mariano* Moreno, Montevideo, Uruguay, Secretariat of the Congress.

International Congress on Neuropathology, Rome, Italy, Sept. 8-13. Dr. Armando Ferraro, 722 W. 168th St., New York, N. Y., U. S. A., Secretary General.

International Congress of Otorhinolaryngology, *Amsterdam,* Netherlands, *June 8-15, 1953.* Dr. W. H. Struben, J. J. Viottastraat 1, Amsterdam, Netherlands, Secretary.

International Congress of Radiology, Copenhagen, Denmark, July 19-25, 1953. Professor Flemming Norgaard, 10 Oster Yoldgade, Copenhagen K., Denmark, Secretary General.

International Congress of Therapeutics, Madrid, *Spain, Oct. 16-18.* Professor Armijo, Instituto de Farmacologia, Cuidad Universitaria, Madrid, Spain, Secretary.

International Congress of Urology, The Waldorf-Astoria, New York, N. Y., U. S. A., Sept. 15-18. Dr. John A. Taylor, 2 East 54th St., New York, N. Y., *U. S. A., Secretary-General.*

International Hospital Congress, London, *England, May 25-30, 1953.* Capt. J. E. Stone, 10 Old Jewry, London, EC2, England, Hon. Secretary.

International Study Conference on Child Welfare, Bombay, India, Dec. 5-12. For information write: All India Save the Children Committee, 5 Carmichael Road, Bombay, India.

International Union Against Tuberculosis, Rio de Janeiro, Brazil, Aug. 24-27. Prof. Etienne Bernard, 66 Blvd. St. Michel, Paris 6e, France, *Secretary-General.*

Medical Women's International Association, Vichy, France, Sept. 12-16. Dr. Margaret M. Wurts, 27 East Wellesley Road, Montclair, N. J., U. S. A., National Secretary.

Neuroradiological Symposium, Stockholm, Sweden, Sept. 17-20. Docent Ake Lindbom, Symposium Neuroradiologicum, Serafimerlasarettet, Stockholm K., Sweden, Secretary.

Pan American Congress of the Medical Press, Buenos Aires, Argentine, July 12-16, 1953. Secretaria del Congress, 763 *Uriburu, Buenos Aires,* Argentine.

World Congress of Medicine, Montecatini, Italy, Oct. 16-18. Secretariat: Corso Trieste, 65, Rome, Italy.

World Federation of Mental Health, Brussels, Belgium, Aug. 25-Sept. 1. Dr. J. R. Rees, 19 Manchester St., London, W.1, England, Secretary.

World Medical Association, Athens, Greece, Oct. 12-16. Dr. Louis H. Bauer, 2 East 103d St., New York 29, N. Y., Secretary General.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Part I,* Sept. 8-10. All centers where there are five or more candidates. Exec. Sec., Dr. John P. Hubbard, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* Swampscott, Mass., Sept. 28-Oct. 1. Sec., Dr. C. B. Hickcox, 80 Seymour St., Hartford 15.

American Board of Dermatology and Syphilology: *Written.* Various Centers, September 1953. Final *date for filing applications* was May 1. All candidates are now required to take the written examination. *Oral.* Philadelphia, October 1953. Ex. Sec., Miss Janet Newkirk, 66 East 66th St., New York 21.

American Board of Internal Medicine: *Written.* Various centers and overseas, *Oct. 20. Closing date for the acceptance of applications for the written examination was May 1. Oral.* San Francisco, Sept. 3-6; Philadelphia, Nov. 13-14 and Washington, D. C., Nov. 17-18. Exec. Sec.-Treas., Dr. William A. Werrell, 1 West Main Street, Madison 3.

American Board of Neurological Surgery: *Written.* New Haven, Sept. 19-21. *Oral.* Chicago, May or June 1953. Final date for filing application for the oral examination is Jan. 15, 1953. Sec., Dr. W. J. German, 789 Howard Ave., New Haven 4, Conn.

American Board of Obstetrics and Gynecology: *Written.* Various Centers, Feb. 6, 1953. Final date for filing applications is Nov. 1. Sec., Dr. R. L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written.* Various Centers, January 1953. Final date for filing applications was July 1. *Practical.* Chicago, Oct. 6-10 and New York City, June 6-10, 1953. Sec., Dr. Edwin B. Dunphy, 56 Ivie Road, Cape Cottage, Maine.

American Board of Orthopaedic Surgery: The deadline for the receipt of applications for the 1953 Part II examinations is Aug. 15. Sec., Dr. Harold A. Sofield, 122 S. *Michigan* Ave., Chicago.

American Board of Otolaryngology: *Written.* Chicago, Oct. 6-10. *Oral.* Chicago, Oct. 6-10 and New Orleans, *April 21-25,* 1953. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City.

American Board of Pathology: *Written and Oral.* Pathologic Anatomy and Clinical Pathology examination. Chicago, Oct. 9-11. Sec., Dr. William B. Wartman, 303 E. Chicago Ave., Chicago 11.

American Board of Pediatrics: *Oral.* Chicago, *Oct. 24-26; Boston, Dec.* 5-7. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: *Oral and Written.* New York, Sept. 26-28. Final date for filing of case reports is Aug. 15. Sec., Dr. Bradford Cannon, 4647 Pershing Ave., St. Louis 8.

American Board of Preventive Medicine and Public Health: Cleveland, Oct. 18-20. Sec., Dr. E. L. Stebbins, 615 N. Wolfe St., Baltimore.

American Board of Proctology: *Oral and Written.* Philadelphia, Sept. 27-28. Sec., Dr. Louis A. Buie, 102-110 *Second Ave., S.W., Rochester,* Minn.

American Board of Psychiatry and Neurology: New *York City, Dec.* 15-16. *Final date for filing applications* is Sept. 15. Sec.-Treas., Dr. David A. Boyd, Jr., 102-110 *Second Ave. S.W., Rochester, Minn.*

American Board of Radiology: *Oral.* Dec. 1-7. Final date for filing application was June 1. *Oral.* Tampa, *April 8-15. Sec., Dr. B. R. Kirklin,* 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers. *October 1952.* Final date for filing application was July 1. *Written.* Various Centers, March 1953. Final date for filing *application is Dec. 1.* Sec., *Dr. J.* Stewart Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: *Written.* Various Centers, *December. Oral.* Chicago, Feb. 7-11. Sec., Dr. Harry Culver, 30 Westwood Road, Minneapolis 16, Minn.

Board of Thoracic Surgery: *Written.* Various Centers, Sept. 5. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2.

DEATHS

Van Hoosen, Bertha ⊕ Rochester, Mich.; born in Rochester, March 26, 1863; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1888; began practice in 1892 in Chicago where she was professor and head of the department of obstetrics at Loyola University School of Medicine from 1918 to 1937, when she became professor emeritus, professor of clinical gynecology at the College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, from 1902 to 1912, and professor of gynecology and embryology at Northwestern University Woman's Medical School from 1894 to 1902; from 1915 to 1918 first president of the Medical Women's National Association, now known as the American Medical Women's Association; member of the Illinois State Medical Society, Chicago Pathological Society, Illinois Academy of Science, Medical Women's International Association, and Daughters of the American Revolution; honorary member of the International College of Surgeons and the International Association of Medical Women; fellow of the American College of Surgeons; served as consultant to Women and Children's Hospital and Lewis Memorial Maternity Hospital in Chicago; formerly affiliated with Misericordia, Provident, Woman's, Mary Thompson, Cook County, and Frances E. Willard hospitals all in Chicago, and Oak Park (Ill.) Hospital; received the honorary degree of master of arts from her alma mater in 1912 and an LL.D. degree from Loyola University in 1926; formerly editor of the *Medical Woman's Journal;* author of "Petticoat Surgeon" published in 1947; died June 7, aged 89.

Bartley, Samuel Potter ⊕ Brooklyn; born in Brooklyn June 6, 1890; Long Island College Hospital, Brooklyn, 1914; clinical associate professor of surgery at University of New York Medical Center; member of the American Association for the Surgery of Trauma and the Industrial Medical Association; fellow of the American College of Surgeons; founder and chairman of the Brooklyn Cancer Committee of the American Cancer Society; for his service during World War I, in 1925 was made a Chevalier of the Legion of Honor by France; affiliated with Kingston Avenue Hospital and House of St. Giles the Cripple in Brooklyn and Huntington (N. Y.) Hospital; died in Long Island College Hospital June 10, aged 62, of leukemia.

Alexander, William Franklin ⊕ Terrell, Texas; Southwestern University Medical College, Dallas, 1905; owner of a hospital bearing his name; died June 6, aged 73.

Alexander, William Graham ⊕ Peoria, Ill.; Northwestern University Medical School, Chicago, 1904; served during World War I; formerly practiced in Evanston, where he was a member of the board of health and school board and affiliated with Evanston and St. Francis hospitals; died June 14, aged 81, of cerebral hemorrhage.

Anderson, Oliver Wendell ⊕ Luverne, Minn.; University of Minnesota Medical School, Minneapolis, 1936; died in Minneapolis April 28, aged 40, of coronary occlusion.

Andrew, James ⊕ Cordova, Ala.; University of Georgia School of Medicine, Augusta, 1922; died March 26, aged 53.

Arthur, Herbert Spencer ⊕ McKeesport, Pa.; Northwestern University Medical School, Chicago, 1902; at one time mayor of McKeesport; formerly on the city school board; vice-president and director of the Daily News Publishing Company of McKeesport; president and director of the Massillon (Ohio) Steel Casting Company; director of the First National Bank of McKeesport; affiliated with McKeesport Hospital; died in Fort Louden June 12, aged 73, of coronary occlusion.

Bach, Arthur ⊕ Lexington, Ky.; University of Louisville Medical Department, 1917; affiliated with St. Joseph Hospital and Good Samaritan Hospital, where he died June 8, aged 58, of pulmonary embolism, following a gastrectomy for duodenal ulcer.

Baketel, Roy Vincent ⊕ Salem, N. H.; Dartmouth Medical School, Hanover, N. H., 1899; member of the Massachusetts Medical Society; formerly practiced in Methuen, where he was school physician, affiliated with Nevins Home for the Aged, and a director of the Methuen National Bank; for many years on the staff of the Lawrence (Mass.) General Hospital; died May 26, aged 75, of a heart attack.

Barnes, Herbert Trumbull ⊕ Delafield, Wis.; Rush Medical College, Chicago, 1903; past president of the Waukesha County Medical Society; served during World War I; for many years health officer of Delafield; resident physician and medical officer at St. John's Military Academy; affiliated with Waukesha (Wis.) Memorial Hospital; died May 15, aged 76, of cancer.

Berwald, William Paul Eugene ⊕ Patton, Calif.; Syracuse University College of Medicine, 1935; affiliated with Redlands Community Hospital in Redlands and Patton State Hospital; died in St. Bernardine's Hospital in San Bernardino June 11, aged 41.

Bowser, William Francis ⊕ Davenport, Iowa; State University of Iowa College of Medicine, Iowa City, 1905; died June 13, aged 79, of carcinoma of the stomach with metastasis and arteriosclerotic heart disease.

Bradner, Frank William ⊕ Brooklyn; Bellevue Hospital Medical College, New York, 1889; active in the National Guard and served as a major in the 13th regiment; for many years affiliated with Kings County Hospital, where he died May 4, aged 83, of cardiovascular disease.

Braislin, Doris Orlenda Tuttle, Rutland, Vt.; Woman's Medical College of Pennsylvania, Philadelphia, 1922; certified by the National Board of Medical Examiners; member of the American Psychiatric Association; died in New York April 11, aged 57, of carcinoma.

Breister, Benjamin Walter ⊕ Chicago; Rush Medical College, Chicago, 1928; on the staff of the Norwegian American Hospital; died in Waukegan, Ill., July 5, aged 59, in an automobile accident.

Breivis, John James ⊕ Binghamton, N. Y.; University of Rochester School of Medicine and Dentistry, Rochester, 1933; for many years county coroner; affiliated with Wilson Memorial Hospital in Johnson City and Binghamton City Hospital, where he died May 8, aged 47, of dissecting aneurysm of the aorta.

Brennan, Albert Edward ⊕ Buffalo; Niagara University Medical Department, Buffalo, 1898; served as health officer of the village of Sloan; on the staff of Emergency Hospital; surgeon for the Delaware, Lackawanna and Western Railroad and Lehigh Valley Railroad for many years; died May 2, aged 77, of dilatation of the heart.

Brooks, Charles Sumner, Mount Union, Pa.; Howard University College of Medicine, Washington, D. C., 1910; died May 17, aged 76.

Brookshire, William Henry, Phoenix, Ariz.; Columbian Medical College, Kansas City, Mo., 1901; died June 11, aged 78, of arteriosclerotic heart disease.

Brown, Stewart Dixon ⊕ Royston, Ga.; Atlanta College of Physicians and Surgeons, 1907; for many years chairman of the board of education; medical superintendent of Cobb Memorial Hospital; served during World War I; died May 20, aged 71, of pulmonary infarction and arteriosclerosis.

Brown, William Lee Jr. ⊕ Chicago; University of Chicago, the School of Medicine, 1942; served in the regular navy during World War II; on the staff of the Illinois Central Hospital, where he died July 10, aged 34, of cor pulmonale.

Brucker, Edward Arthur ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1916; on the staff of St. Anne's Hospital; died May 27, aged 62, of coronary occlusion.

⊕ Indicates Member of the American Medical Association.

Brumbaugh, Gaius Marcus ⊕ Washington, D. C.; Howard University College of Medicine, Washington, 1885; Georgetown University School of Medicine, Washington, 1888; for many years president and later president emeritus of the board of trustees of Juniata College in Huntington, Pa.; died May 14, aged 90, of hypertensive cardiovascular disease.

Bryson, Edmond Jones, Liberty, S. C.; Bennett Medical College, Chicago, 1913; for many years mayor of Liberty; served during World War I; formerly health officer of Greenwood, Oconee, and Pickens counties; died May 29, aged 66, of cerebral hemorrhage.

Cannon, John Henry, Shreveport, La.; University of the South Medical Department, Sewanee, Tenn., 1900; past president of the city board of health; formerly city health officer; died May 5, aged 85, of arteriosclerotic heart disease.

Childers, Joseph Edward, Tipton, Okla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1915; county health officer; formerly a physician in the Indian Service; examiner for the selective service board during World War II; physician for the Missouri, Kansas and Texas Railway; died June 1, aged 65, of coronary disease.

Ciccone, George Vico, Philadelphia; Medico-Chirurgical College of Philadelphia, 1901; also a graduate in pharmacy; member of the selective service board during World Wars I and II; died May 9, aged 76, of carcinoma of the prostate.

Collier, Thomas Jefferson ⊕ Atlanta, Ga.; Atlanta College of Physicians and Surgeons, 1900; chairman, Section on Anesthesiology, American Medical Association, 1941-1942; past president of the Associated Anesthetists of the United States and Canada; member of the American Society of Anesthesiologists; specialist certified by the American Board of Anesthesiology; served during World War I; affiliated with Piedmont Hospital, where he died March 10, aged 77, of cerebral hemorrhage.

Colson, Dell Cassidy, Glenwood, Ga.; University of Georgia School of Medicine, Augusta, 1914; died May 16, aged 70, of carcinoma of the bladder.

Cook, Samuel LeCount, Washington, D. C.; University of Illinois College of Medicine, Chicago, 1913; clinical assistant professor of gynecology at Howard University College of Medicine; died in Rochester, Minn., June 11, aged 64.

Davies, Morgan Cryder ⊕ Columbus, Ohio; Ohio State University College of Medicine, Columbus, 1927; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; affiliated with White Cross Hospital and Children's Hospital; died May 26, aged 56, of myocardial infarction.

Dennis, Thomas Edmund ⊕ Monroeville, Ala.; University of the South Medical Department, Sewanee, Tenn., 1908; died March 2, aged 78, of acute coronary occlusion.

Donn, Frederick Young, Washington, D. C.; George Washington University School of Medicine, Washington, D. C., 1915; died June 7, aged 63, of arteriosclerotic heart disease.

DuBose, David J., Purvis, Miss.; Mississippi Medical College, Meridian, 1910; died in Methodist Hospital, Hattiesburg, May 21, aged 72, of arteriosclerosis.

Fitz, Erwin Otto L., Milwaukee; Marquette University School of Medicine, Milwaukee, 1914; died in Veterans Administration Hospital, Marion, Ind., March 17, aged 62, of pulmonary tuberculosis.

Fleck, Harry Willard ⊕ Stratford, Conn.; Jefferson Medical College of Philadelphia, 1896; formerly practiced in Bridgeport, where he was affiliated with St. Vincent's and Bridgeport hospitals; died May 8, aged 79, of chronic myocarditis and arteriosclerosis.

Flournoy, Harrison Clinton ⊕ Warwick, Ga.; Vanderbilt University School of Medicine, Nashville, Tenn., 1911; died May 4, aged 66, of coronary infarction.

Friesleben, William ⊕ Sauk Rapids, Minn.; Medical College of Ohio, Cincinnati, 1906; past president of the Stearns-Benton Counties Medical Society; past president of the Benton County Fair Association; served on the school board; member of the American Academy of General Practice; died May 20, aged 73, of angina pectoris.

Fulda, Harry Christian, Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1908; died May 21, aged 66, of coronary occlusion.

Gallupe, Harold Quimby ⊕ Waltham, Mass.; Harvard Medical School, Boston, 1918; secretary of the Massachusetts Medical Society; formerly secretary of the state board of registration in medicine; served on the staff of the Waltham Hospital, where he died May 29, aged 63, of cancer.

Gauen, George Otto ⊕ St. Louis; Washington University School of Medicine, St. Louis, 1904; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; served as chief of obstetrics at Lutheran Hospital, where he died June 6, aged 71, of uremia and heart disease.

Gifford, Allen William ⊕ Springfield, Mo.; Central College of Physicians and Surgeons, Indianapolis, 1901; died in Burge Hospital April 3, aged 78, of arteriosclerotic heart disease.

Gossom, Kelley D. ⊕ Clinton, Okla.; Hospital College of Medicine, Louisville, 1903; died in Western Oklahoma State Hospital May 15, aged 74, of acute myocardial insufficiency.

Gregory, William Grant, Tampa, Fla.; Rush Medical College, Chicago, 1891; died in Bay Pines recently, aged 88, of adenocarcinoma of the stomach with metastases to liver, lungs, and regional lymph nodes.

Griffis, Frank C. ⊕ Major, U. S. Army, retired, Fruitland Park, Fla.; Ohio Medical University, Columbus, 1896; entered the medical corps of the U. S. Army in 1917 and retired Nov. 30, 1930; died recently, aged 85, of arteriosclerotic heart disease.

Group, George Abraham, Syracuse, N. Y.; Syracuse University College of Medicine, 1919; associated with the city health department; served as assistant professor of medicine (syphilology) at his alma mater; died in St. Joseph's Hospital May 18, aged 59, of acute myocardial infarction.

Guild, William Alva ⊕ Coral Gables, Fla.; Chicago Homeopathic Medical College, 1903; Kansas City College of Medicine and Surgery, Kansas City, Mo., 1922; member of the Illinois State Medical Society; died in Miami Springs recently, aged 72, of hypertension and cancer of the large bowel.

Gullo, Charles ⊕ Buffalo; Loyola University School of Medicine, Chicago, 1928; past president of the Livingston County Medical Society; certified by the National Board of Medical Examiners; formerly affiliated with Dansville (N. Y.) Memorial Hospital; died in Oneida, N. Y., April 12, aged 52.

Gustafson, Axel Walfred ⊕ Gustine, Calif.; College of Physicians and Surgeons, Los Angeles, 1922; served during World War I; health officer and school physician; died in West Side Hospital in Newman May 14, aged 71, of cerebral hemorrhage.

Halpern, Harry Samuel, Philadelphia; Jefferson Medical College of Philadelphia, 1911; for many years medical inspector of the board of education; died June 2, aged 63.

Ham, Cornelius, Baltimore; Atlantic Medical College, Baltimore, 1910; died recently, aged 83, of cerebral hemorrhage.

Hatcher, George Edward ⊕ Cerulean, Ky.; University of Tennessee Medical Department, Nashville, 1906; member of the American Academy of General Practice; past president of the Trigg County Medical Society; served as a member of the county board of health; died May 25, aged 69, of a heart attack.

Hazard, John David ⊕ Albany, N. Y.; New York Medical College, Flower and Fifth Avenue Hospitals, in New York, 1942; certified by the National Board of Medical Examiners; served during World War II; resident at Veterans Administration Hospital, where he died June 22, aged 36.

Holbrook, Charles Albert ⊕ Haverhill, Mass.; Harvard Medical School, Boston, 1908; affiliated with Hale Hospital, where he died April 9, aged 73, of arteriosclerotic heart disease.

Holt, Rufus Andrew ⊕ Los Angeles; College of Physicians and Surgeons, Medical Department of the University of Southern California, Los Angeles, 1915; affiliated with California Lutheran Hospital; died May 16, aged 61.

Hoppe, Herman C., Columbus, Ohio; Ohio Medical University, Columbus, 1901; also a graduate in pharmacy; died May 30, aged 82, of pulmonary edema.

Isbell, Jesse E. D. ⊕ Toccoa, Ga.; Atlanta College of Physicians and Surgeons, 1901; served overseas during World War I; died April 30, aged 75.

Jenson, James ⊕ Saybrook, Ill.; Chicago College of Medicine and Surgery, 1911; died in Bloomington recently, aged 74, of coronary heart disease.

Johnson, Arnold Edwin ⊕ Minneapolis; Rush Medical College, Chicago, 1902; died in St. Barnabas Hospital recently, aged 76, of cerebral hemorrhage and hypertension.

Jonnes, Lloyd ⊕ Circleville, Ohio.; University of Cincinnati College of Medicine, 1918; served during World War I; a captain in the Ohio National Guard for many years; West Virginia state medical inspector for Civilian Conservation Corps from 1935 to 1937; coroner of Pickaway County since 1945; district medical officer, Norfolk and Western and Chesapeake and Ohio Railroads; president, Ohio History Day Association; owner, Park Place Press; died May 21, aged 62.

Kelley, Clarence Joseph, Washington, D. C.; Georgetown University School of Medicine, Washington, 1936; died in Providence Hospital July 3, aged 41, of bleeding gastric ulcer.

Kelty, Harvey Egbert, Chico, Calif.; Willamette University Medical Department, Salem, 1906; also a graduate in dentistry; veteran of the Spanish-American War; for many years practiced in Lakeview, Ore., where he was county judge and county health officer; died June 5, aged 72, of carcinoma of the colon.

Keough, Matthew Joseph, Cohoes, N. Y.; Albany (N. Y.) Medical College, 1905; formerly commissioner of health of Cohoes, and first medical director for Cohoes public and parochial schools; served during World War I; for many years affiliated with Cohoes Hospital, where he died April 30, aged 76, of cerebral hemorrhage.

Kerrick, Charles L., Chrisman, Ill.; Kentucky School of Medicine, Louisville, 1893; Medical College of Indiana, Indianapolis, 1894; president of the State Bank of Chrisman; died in Veterans Administration Hospital, Danville, May 20, aged 83, of bronchopneumonia.

Kidd, Claude Everitt, Paducah, Ky.; University of Louisville Medical Department, 1907; at one time county health officer; served on the staffs of the Illinois Central and Riverside hospitals; died May 8, aged 80, of cerebral thrombosis.

Lange, Pauline E. ⊕ Chicago; Hering Medical College, Chicago, 1900; at one time on the faculty of her alma mater; affiliated with Illinois Masonic Hospital, where she died June 17, aged 76, of coronary insufficiency, pulmonary embolism, and carcinoma of the cervix.

Lecrone, Harris Richard ⊕ York, Pa.; Jefferson Medical College of Philadelphia, 1885; surgeon emeritus at York Hospital; died May 11, aged 91.

Leonard, Ralph Davis, Boston; Harvard Medical School, Boston, 1910; specialist certified by the American Board of Radiology; member and past vice-president of the American Roentgen Ray Society; past president of the New England Roentgen Ray Society; president of the Melrose Savings Bank; affiliated with Brooks Hospital in Brookline, Malden (Mass.) Hospital, and Melrose Hospital, where he died May 27, aged 65, of a heart attack.

Lesser, Henry Rothschild, Toledo, Ohio; Medico-Chirurgical College of Philadelphia, 1906; died in Toledo Hospital March 29, aged 68, of cerebral hemorrhage.

Lipsett, Henry, Rochester, N. Y.; University of Toronto Faculty of Medicine, 1920; died in Strong Memorial Hospital May 19, aged 57, of nephrosclerosis and arteriosclerosis.

Littlefield, Frank Browning ⊕ Providence, R. I.; Harvard Medical School, Boston, 1926; certified by the National Board of Medical Examiners; fellow of the American College of Surgeons; member of the New England Surgical Society; served during World War II; affiliated with Rhode Island and Charles V. Chapin hospitals; died in Jane Brown Memorial Hospital June 3, aged 52.

Lowe, Lewis Morgan, Seattle; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; died May 19, aged 76, of acute coronary occlusion.

Lutterloh, Pearlie Watson ⊕ Jonesboro, Ark.; Washington University School of Medicine, St. Louis, 1910; associate clinical professor of surgery, University of Arkansas School of Medicine, Little Rock; past president of the Arkansas Medical Society, Frisco Railway Surgeons Association, and the Mid-South Post Graduate Medical Assembly; associated with St. Bernard's Hospital; died May 15, aged 67, of coronary artery disease.

McCrumb, Ray Richmond ⊕ Lansing, Mich.; Detroit College of Medicine and Surgery, 1914; affiliated with Edward W. Sparrow and St. Lawrence hospitals; died May 5, aged 65, of cerebral thrombosis.

McGarry, Charles Patrick, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; affiliated with St. Francis Hospital in Evanston, where he died June 2, aged 70, of coronary occlusion.

McGready, Joseph Hugh ⊕ Independence, Iowa; College of Physicians and Surgeons of Chicago, 1896; city health officer; died May 11, aged 80, of uremia and chronic myocarditis.

MacKenzie, Charles Fisk, Jackson, Miss.; Vanderbilt University School of Medicine, Nashville, 1904; medical missionary in China for many years; formerly medical director for the Standard Life Insurance Company; died May 3, aged 84, of cerebrovascular accident and congestive heart failure.

McPherrin, Henry Irl ⊕ Des Moines, Iowa; Drake University College of Medicine, Des Moines, 1912; served during World War I; died April 9, aged 65.

Maas, Elizabeth C., Rockford, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1894; died in North Rockford Hospital May 17, aged 92, of cerebral hemorrhage.

Mallette, Lester Birch ⊕ San Francisco; Northwestern University Medical School, Chicago, 1944; specialist certified by the American Board of Radiology; served during World War II; formerly affiliated with Peoples Hospital in Akron, Ohio; died May 15, aged 32, of coronary thrombosis.

Marable, John Hartwell, Cowan, Tenn.; Vanderbilt University School of Medicine, Nashville, 1898; died in Winchester (Tenn.) Hospital April 6, aged 77.

Marchmont-Robinson, George ⊕ Chicago; Loyola University School of Medicine, Chicago, 1917; died June 14, aged 67.

Marquart, James Roger ⊕ Springfield, Ohio; Ohio State University College of Medicine, Columbus, 1926; member of the American Academy of General Practice; served during World Wars I and II; medical director of the Ohio Masonic Home; affiliated with Rickley Memorial Hospital; physician at Wittenberg College; died May 23, aged 52, of coronary occlusion.

Marshall, Hal Ellsworth ⊕ Wichita, Kan.; University of Kansas School of Medicine, Kansas City, Mo., 1925; specialist certified by the American Board of Otolaryngology; past president of the Sedgwick County Medical Society; member of the American Academy of Ophthalmology and Otolaryngology; on the staff of St. Francis Hospital, where he died June 15, aged 55, of coronary sclerosis.

Martin, Carman Ira ⊕ Akron, Ohio; Medical College of Virginia, Richmond, 1927; since 1948 county coroner; affiliated with St. Thomas Hospital and City Hospital, where he died May 16, aged 50, of acute coronary occlusion.

Miller, Charles Hyette ⊕ Dalhart, Texas; Memphis (Tenn.) Hospital Medical College, 1898; died in Northwest Texas Hospital, Amarillo, April 26, aged 78, of multiple fractures and internal injuries received in an automobile accident.

Mol, Henry L. ⊕ Grundy Center, Iowa; Northwestern University Medical School, Chicago, 1926; member of the American Academy of General Practice; died in Allen Memorial Hospital, Waterloo, June 3, aged 55, of coronary thrombosis.

Moldenhauer, Gustav H. ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; an Associate Fellow of the American Medical Association; surgeon for the Illinois Central Railroad; died in Pinal Sanitarium May 17, aged 77, of carcinoma of the breast.

Mongel, Ernest Bernhardt, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1899; affiliated with Wills Eye Hospital and the Episcopal Hospital; died May 12, aged 76.

Moody, Joseph Warren, Poplarville, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1906; formerly affiliated with Sunflower Hospital (State Penitentiary) at Parchman; died in Methodist Hospital, Hattiesburg, May 2, aged 77, of cerebral hemorrhage.

Moore, Luman Gordon Jr., Kinsman, Ohio; Western Reserve University Medical Department, Cleveland, 1906; served during World War I; died May 7, aged 71.

Moore, Telford Ira ⊕ North Hollywood, Calif.; University of Illinois College of Medicine, Chicago, 1934; specialist certified by the American Board of Ophthalmology; served during World War II; shot and killed May 6, aged 45.

Moorman, Marion Ridley ⊕ Huntsville, Ala.; University of the South Medical Department, Sewanee, Tenn., 1900; died April 13, aged 73, of bronchitis and chronic myocarditis.

Myers, Frank Lewis, Sheldon, Iowa; College of Physicians and Surgeons of Chicago, 1888; died recently, aged 87, of pneumonia.

Owsley, William McGehee ⊕ Eclectic, Ala.; University of Alabama School of Medicine, 1914; died recently, aged 65, of cerebral hemorrhage.

Paterson, William Frederick ⊕ Conrad, Mont.; McGill University Faculty of Medicine, Montreal, Canada, 1900; on the staff of St. Mary's Hospital; died May 2, aged 77, of coronary thrombosis.

Patterson, Henry Hooker ⊕ Braymer, Mo.; Ensworth Medical College, St. Joseph, 1904; past president of the Caldwell-Livingston Counties Medical Society; died May 9, aged 81, of cerebral hemorrhage.

Porter, Earl Stevens ⊕ La Jolla, Calif.; Rush Medical College, Chicago, 1909; member of the Montana State Medical Association and past president of the state board of medical examiners of Montana; died in Eugene, Ore., recently, aged 69, of coronary occlusion.

Price, John Beadle, Norristown, Pa.; Medico-Chirurgical College of Philadelphia, 1914; specialist certified by the American Board of Otolaryngology; served during World War I; district medical director for the state health department; on the staffs of the Graduate Hospital of the University of Pennsylvania and Montgomery Hospital; died May 11, aged 68.

Price, Melvin Delbert ⊕ Nappanee, Ind.; Medical College of Indiana, Indianapolis, 1900; an Associate Fellow of the American Medical Association; physician for the Baltimore and Ohio Railroad; for many years part owner of the Price & Price Hospital; affiliated with Elkhart General Hospital in Elkhart, Ind., where he died May 31, aged 81, of heart failure.

Reed, Fred Romer ⊕ Three Rivers, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1914; fellow of the American College of Surgeons; affiliated with Three Rivers (Mich.) Hospital, Sturgis (Mich.) Memorial Hospital, and the auxiliary staff, Grace Hospital in Detroit; died June 2, aged 62, of myocardial infarction.

Reed, Guy Pace ⊕ Davis City, Iowa; St. Louis College of Physicians and Surgeons, 1899; died May 24, aged 77, of a perforated gallbladder.

Rhodes, William J. ⊕ Louisville, Ga.; University of Georgia Medical Department, Augusta, 1884; died recently, aged 94, of carcinomatosis.

Richardson, James Covington, Miami, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1920; died May 25, aged 57, of congestive rheumatic heart disease.

Riche, H. Guy ⊕ Baton Rouge, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1899; past vice-president of the Louisiana State Medical Society; vice-president and medical director of the Guaranty Income Life Insurance Company; past chief of staff of Our Lady of the Lake Sanitarium, where he died April 24, aged 76, of adenocarcinoma of the colon.

Ridgway, Alfred M. ⊕ Annandale, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1890; also a pharmacist; served as mayor of Annandale; died May 19, aged 90, of coronary insufficiency and bronchopneumonia.

Robbins, Charles Sumner ⊕ Washington, D. C.; Rush Medical College, Chicago, 1901; died June 12, aged 75.

Roberts, Peter Franklin, Raleigh, N. C.; Leonard Medical School, Raleigh, 1907; served on the faculty of his alma mater; died recently, aged 71, of cerebral hemorrhage.

Robertson, Andrew Alexander ⊕ Council Bluffs, Iowa; Medical Department of Omaha University, 1901; died recently, aged 74, of cerebral hemorrhage and arteriosclerosis.

Rodenmayer, Henry, Bloomington, Calif.; Barnes Medical College, St. Louis, 1905; died in San Bernardino May 6, aged 71, of hypertensive heart disease.

Root, Peter Nathaniel ⊕ Bakersfield, Calif.; University of Oregon Medical School, Portland, 1924; died recently, aged 64, of arteriosclerosis.

Rosen, Samuel Richard ⊕ New York; born in Brockton, Mass., Jan. 9, 1912; Albany (N. Y.) Medical College, 1937; specialist certified by the American Board of Psychiatry and Neurology; certified by the National Board of Medical Examiners; member of the American Psychiatric Association; served in Italy during World War II, and received the Bronze Star; affiliated with Goldwater Memorial and Mount Sinai hospitals; council member of the University Settlement; died in the Hospital for Joint Diseases May 24, aged 40, of coronary occlusion.

Rugh, John B. ⊕ Pitcairn, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1897; died May 4, aged 81, of coronary occlusion.

Rumph, Thomas Gladstone ⊕ Fort Worth, Texas; University of Louisville (Ky.) Medical Department, 1913; died May 31, aged 65, of intracranial hemorrhage and arterial hypertension.

Ryder, Bayard Edward ⊕ Los Angeles; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; died May 17, aged 77, of cerebral hemorrhage.

Sandoz, Louis Albert ⊕ South Bend, Ind.; University of Louisville School of Medicine, Louisville, Ky., 1924; member of the American Academy of Dermatology and Syphilology; affiliated with Memorial and St. Joseph hospitals; died in St. Joseph Hospital, Lexington, Ky., May 13, aged 56, of adenocarcinoma of the left colon and peritonitis.

Thomas, Earl Jesse, Findlay, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; fellow of the American College of Physicians; served for many years on the board of directors of the First National Bank; died in Blanchard Valley Hospital May 23, aged 69, of cerebral vascular accident.

Thompson, Floyd C. ⊕ Ontario, N. Y.; Cleveland Homeopathic Medical College, 1905; for many years health officer; formerly a member and president of the local school board; died in the Genesee Hospital, Rochester, May 7, aged 75, of myocardial infarction, diabetes mellitus, and thrombophlebitis of the right leg.

Wright, LaVerne ⊕ San Francisco; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901; member of the American Society of Anesthesiologists; died recently, aged 73, of a cerebral accident.

GOVERNMENT SERVICES

AIR FORCE

Aviation Medical Examiners.—In July, in the new class of aviation medical examiners at the Air Force School of Aviation Medicine, Randolph Field, Texas, 93 student officers enrolled. Five officers of foreign air forces are in the class. The two from Pakistan are the first Pakistani students at the school, which has graduated flight surgeons of 33 other foreign countries. The class contains nine rated pilots, and all but three have had World War II experience overseas. The Navy has contributed 24 of these medical officers to the Air Force. Most of them were trained under the seagoing arm's V-12 program. This class is the first to include two veterans of the war in Korea.

ARMY

Personal.—Col. Dean M. Walker, chief of the department of surgery, Tripler Army Hospital, Moanalua, Hawaii, is retiring from the Army after 25 years' service and will enter private practice, limited to general surgery, in Honolulu.

Recall 500 Reserve Nurses.—The recall to active military service of 500 reserve Army nurses and 125 reserve women's medical specialists was approved July 31 by the Assistant Secretary of Defense. Included in the recall of reservists from the Women's Medical Specialist Corps are 70 dietitians, 31 physical therapists, and 24 occupational therapists. The first involuntary recall of women reservists in the medical branches of the Army since early in the Korean campaign is needed to replace women about to be released from active duty. The National Advisory Committee of the Selective Service System was directed to assure that no person essential to the national health, safety, and interest will be obliged to leave her civilian job. Those who have been recalled since June 25, 1950, will not be affected by this recall. The call-up will continue for three months beginning in February, 1953. Of those to be ordered to active duty 50% are scheduled for recall the first month and 25% in each following month. Reservists selected for recall will be given at least 120 days' notice in which to close out personal business.

PUBLIC HEALTH SERVICE

Personal.—Dr. James R. Shaw has been appointed chief, division of hospitals, Public Health Service, succeeding Dr. G. Halsey Hunt, who was named associate chief, bureau of medical services. Dr. Shaw will have charge of the 22 hospitals, 19 outpatient clinics, and over 100 outpatient offices operated for the beneficiaries of the Public Health Service. The division of hospitals is part of the bureau of medical services, of which Dr. Jack Masur is chief.

Marriages and Divorces.—The marriage rate in 1951 dipped to its lowest point since 1938, and the divorce rate to the lowest since 1941, according to provisional vital statistics released by the Public Health Service. The 1951 marriage rate—10.4 per thousand population—showed a 37% drop from the 1946 all-time peak. Since the postwar demobilization period, marriage rates have generally fallen off as the wave of marriages reduced the number of single persons of marrying age. During the past few years the number of young persons reaching marrying age has been relatively small because of low birth rates during the business depression of the early 1930's.

Marriages in 1951 totaled 1,594,900, or 72,300 fewer than in 1950. The marriage rate fell by 6%. An estimated 371,000 divorces were granted in 1951, compared with 385,100 divorces in 1950. The 1951 total includes reports from 32 states and the District of Columbia, and an estimate based on 1950 divorces in states not reporting last year. For every 1,000 persons, 2.4 divorces were granted in 1951, compared with 2.5 in 1950. Since the 1946 all-time peak, the divorce rate has dropped 44%.

Meetings of Advisory Councils.—Seven of the National Advisory Councils to the Public Health Service met during June. The councils consist of outstanding nongovernmental experts in medical sciences, public health, and public affairs. They have as ex officio members representatives of the Public Health Service, the Veterans Administration, and the Department of Defense. The councils were established by law to advise the Surgeon General on health problems in their respective fields. One of their important functions is to make recommendations for research grants to nonfederal institutions. The councils which met in June were the Mental Health Council, Arthritis and Metabolic Diseases Council, National Advisory Health Council, Cancer Council, Dental Research Council, Neurological Diseases and Blindness Council, and Heart Council.

VETERANS ADMINISTRATION

Hospital News.—Dr. Gregory Zilboorg, New York, addressed the members of the hospital staff at the VA Hospital, Northport, L. I., June 2, on "The Major Difficulties in Psychotherapy," and Dr. Ben Karpman, clinical professor of psychiatry at Howard University, Washington, D. C., June 19, on "Psychiatric Findings in Criminals."

Residencies in Psychiatry.—Residencies in psychiatry are available at the Veterans Administration Hospital, Hines, Ill., beginning Oct. 1, 1952, and Jan. 1, 1953, for a period of three years. The residency program is under the direction of the Department of Psychiatry, University of Illinois. The hospital is within commuting distance of all other psychiatric facilities in the Chicago area. The training is fully accredited by the American Board of Psychiatry and Neurology.

Personals.—Dr. Jesse F. Casey, manager of the Veterans Administration Hospital at Topeka, Kan., has been transferred to the VA Central Office in Washington, D. C., as Chief of the Hospital Psychiatry Section. Dr. Casey, who joined VA in 1930, succeeds Dr. A. H. Fachner, who has been appointed manager of the new VA Hospital in Salt Lake City, which is scheduled to be dedicated next fall.——Mr. Bert C. Moore has been appointed manager of the Veterans Administration Center in Dayton, Ohio, comprising a 1,120-bed general hospital and a 2,098-bed domiciliary unit. Mr. Moore has spent most of his 30 years' service with VA and its predecessor agencies in a managerial capacity.

Repairs for Veterans' Wheel Chairs.—More than 20,000 disabled veterans who use wheel chairs because of service-connected disabilities will be able to get emergency repairs for them without prior Veterans Administration approval. VA regional offices across the country will soon begin to issue a new "Prosthetic Service Card—Wheel Chairs" to each veteran entitling him to the new service. These veterans will get prompt service from commercial concerns or VA when they need emergency or major repairs. On presentation of the service card at any commercial repair shop, the veteran may receive emergency repairs up to $15 for each wheel chair. On-the-spot eligibility for major repairs or emergency replacement of wheel chairs at any of the 30 VA orthopedic shops located throughout the country also can be established by this card. Heretofore, veterans had to obtain prior approval from VA before emergency repairs to wheel chairs could be authorized.

FOREIGN LETTERS

CHILE

Alcoholism.—One of the main topics discussed at a clinical meeting held in Vina del Mar during January, 1952, was the subject of alcoholism. Dr. I. Roizblat pointed out the importance of the problem in Chile. The total number of persons arrested for drunkenness in Chile during 1940 was 120,000. Nine years later the number increased to 217,000. The maximal number of persons were within the ages of 25 and 34 (32%), followed by the group 35-44 years old (27%). Of those arrested, 147,688 had a primary education only, 9,177 a secondary education, and 156 were university graduates; 58,000 were illiterates. Men made up 98% of the cases, and there were twice as many unmarried as married men. After carefully analyzing the advantages and disadvantages of the conditional reflex treatment Dr. Roizblat prefers dipsotherapy. The author plans an anti-alcohol campaign.

Dr. F. Beca studied the question of psychopathology and some of the psychic disorders produced by alcoholism. He put special emphasis on encephalopathy and alcoholic dementia. The number of cases presented was 130. Sixty-four patients belonged to the encephalopathic group. The author reminded the audience that in 1947 he and Prof. Egana studied 18 patients (7 cases of delirium tremens and 8 of alcoholic encephalopathy) and noted a decrease of the blood level of thiamine, the level of which was also decreased in the spinal liquid and in the urine. The level was corrected by the administration of thiamine, but no influence on the symptoms was seen. Of the 490 cases of alcoholic psychosis that left the Manicomio Nacional, only 8% corresponded to delirium tremens. Dr. Beca thinks that this phenomenon is due to the fact that wine is drunk much more than brandy and that the majority of the consumers are men.

Some aspects of the personality of the alcoholic were studied by A. Arcaya and A. Schneider. The authors made a complete medical check-up and a neurological and psychiatric examination, giving great importance to the Rorschach test. Of 533 cases the diagnosis of ethylism could be made in 72 cases, and only 7 presented symptoms of psychosis. In the majority of cases the patients started to work at a very early age, 12-14 years old, and started to drink between the ages of 14 and 20. The authors explain that during puberty the "paternal image" is of great importance; the youth either tries to identify himself with it or else to reject it. The best friend takes the place of the paternal image, and his attitude towards alcoholism is of fundamental importance. The patients had adequate incomes, and, therefore, the authors rejected the idea that poverty or hypoalimentation was a direct cause of alcoholism; however, alcoholism was the cause of later lack of employment. The majority of the patients had neurotic manifestations since childhood. These manifestations were accentuated with the use of alcohol. The inadaptability of the patient to the environment was another reason. The family was often characterized by the presence of an oversolicitous mother filled with neurosis, by the early death of the father, or by the parents' divorce. The authors believe that the addiction to alcohol is, in the vast majority of cases, the result of repeated frustrations in early childhood that prolonged the oral phase to the advanced stages of life.

The neurological aspects of alcoholism were studied by Prof. Lea-Plaza and colleagues, who presented 215 cases of confirmed and inveterate alcoholics. The patients were divided into two groups. The first group, in which alcohol was the main determining factor of the clinical picture, were patients who suffered from neuromyelosis, myelosis, encephalomyelosis, neuritis, and polyneuritis. The total number of patients in this group was 145. In the second group, in which alcohol was only one factor, were patients suffering from epilepsy and vascular accidents. The total number of persons in this group was 168. The authors point out that it seems to them that chronic alcoholism acts in a diffuse manner on the central and peripheral nervous systems.

Professor Mardones studied the experimental problems of alcoholism. He pointed out that if we accept the theory that in problems of human alcoholism there are two aspects, one the biochemical one and the other the psychological one, we must then conclude that experimental alcoholism performed in animals in autoselection will only give us light regarding the biochemical aspect of the problem. The author observed individual variations in the conduct of animals to alcohol, and he showed that there exist conditions transmissible by heredity that influence alcoholism. Regarding the food factor, the author noted that mice that received a diet free of thiamine increased their consumption of alcohol and that the posterior administration of thiamine did not decrease their consumption.

Dr. L. Acevedo and colleagues presented the results of the medical treatment of alcoholism. They found that better results were obtained in those patients that willingly submitted to therapy and that the cultural standard of the patient influenced to a great extent the success of the treatment. Another point of interest was the fact that the greater the economic sacrifice the patient had to make to undergo therapy the better the results obtained. Of the 161 persons treated, 70% were chronic alcoholics and 30% had, besides alcoholism, a psychotic personality. The success achieved was around 50% among professional persons and only 35% among nonprofessional employees.

Neutralization Test of Poliomyelitis Virus in Santiago.—After analyzing and summarizing the history and epidemiology of poliomyelitis, Dr. Cattaneo noted that each successive poliomyelitis wave in Chile is increased in the number of cases involved. If the disease in its endemic form is new in Chile, then the majority of the population will be susceptible to the disease. For this reason the author, in 1949, investigated this problem for the first time in Chile. An analysis of the population of Santiago of different ages was made, using the Lansing test of neutralization. If the proportion of positive tests is comparable to those in the United States or European countries, then the time of introduction of poliomyelitis in Chile is similar to that in the above-mentioned countries, thereby showing that a high percentage of subclinical cases is responsible for the phenomenon. The study was facilitated to a great extent by the fact that in 1949-1950 there was a poliomyelitis epidemic. The patients were divided in three groups: (1) those under 5 years old, (2) those from 5 to 15 years old, and (3) those over 16 years old. No selection was made in the cases that were studied, thereby ensuring a cross section of the population. The results obtained were as follows: positive tests under 5 years of age, 48%; between 5 and 15, 98%; and over 16 years, 94%.

Thus it is apparent that the antibody increases with age, this being due to a subclinic phenomena. Turner in the United States reported similar figures. In 1950 there was an epidemic, from which 50 more patients under 5 years old were included. There were 58% who had positive tests, which, when compared with the 48% of the normal cases presumably positive, show no statistical significance whatsoever. The author does not accept as an explanation for this fact the possible late increase of antibodies, because all known data up to date contradicts that fact. The author explains this phenomenon by saying that the latest Chilean epidemic was not due to the Lansing strain and that the percentage of positivity to the strain was due to a contact with the strain previous to the sickness.

Fourth International Congress of Hydatid Disease.—It was recently announced that the Fourth International Congress of Hydatid Disease will be held in Santiago between Nov. 21 and 24, 1952. This congress will be held simultaneously with the Fourth National Congress of Surgery. The Chilean government through the Ministry of Public Health will sponsor the congress. The medical, surgical, immunologic, and epidemiological

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

aspects of the disease will be treated in the congress. All communications should be addressed to P. O. B. 9183, Santiago de Chile.

Postgraduate Courses.—A second postgraduate course was solemnly inaugurated on June 30. The main object of the course is to give training in up-to-date methods to physicians from out of Santiago preferably. The capacity of the course is approximately 40, and it will last around 1½ months. During this time the mornings will be spent in the main hospitals of the capital doing practical work in internal medicine (electrocardiography and radiology) and clinical cases, whereas the afternoon will be dedicated to problems of internal medicine. Problems of nutrition and dietetics will also be treated. It was announced that the first postgraduate course in surgery will open on July 21. The following specialities will be included: abdominal surgery, esophageal and thoracic surgery, plastic surgery, orthopedics and traumatology, and proctological surgery. Each subject will be treated with theoretical lectures, practical and clinical work, and operations. Every pupil will attend all the theoretical lectures, but in the practical field he will choose only one subject.

DENMARK

New Morbidity Census.—Just before World War II plans were prepared by Dr. J. Frandsen, head of the Danish Public Health Service, for a morbidity census in Denmark. These plans are now being realized owing to the support of the Rockefeller Foundation, certain Danish organizations, and the government. A representative committee was appointed early in 1950 to put these plans into execution, and early in 1951 they were tested in Copenhagen and some country districts to make sure that they worked well. The census itself was started in June, 1951, and it is hoped that in the course of the following three years some 100,000 persons will have been questioned in regard to their health and the social conditions under which they live. The census is carried out by social workers, nurses, and various other persons specially trained for the purpose and enjoined to observe professional secrecy with regard to the information they collect. The questions set for this census are asked by laymen and answered by laymen, with the result that the information gained is of somewhat limited scientific value and requires close medical scrutiny. To this end the cooperation of the physicians in attendance on the persons questioned is needed. The Danish Medical Association has been approached on this subject, and it is arranged that the part to be played by the medical profession is to be as light as possible. It is hoped that this census of a typical cross section of the population of Denmark will yield valuable information with regard to morbidity and social conditions.

Causes of Death in Diabetics.—Two studies by Dr. Frantz Heintzelmann, of the Medical Statistical Bureau of the Danish Public Health Service, deal with the 2,620 deaths of diabetics during the three year period 1947-1949. Before 1947, the notifications of the deaths of diabetics did not always distinguish between deaths among diabetics and deaths due to diabetes. Since January of this year an attempt has been made to render death certificates more informative on this score. Dr. Heintzelmann finds that since 1936 the annual number of deaths among diabetics has remained fairly constant at about 20 per 100,000 of the population, the sex distribution during the three years under review showing 38.5 men to 61.5 women. The observation that deaths among diabetics has been fairly constant during the past 15 years is to a certain extent confirmed by Per Hanssen, who found that in Bergen, Norway, there had been no change in the total diabetes mortality between 1929 and 1940.

Most of Heintzelmann's 2,620 deaths were due to degenerative changes in the heart. It was chiefly between the ages of 45 and 64 that this cause of death predominated, but it was also important among men between the ages of 15 and 44. Renal disease and tuberculosis were also frequent causes of death, and in childhood death was almost always due to a diabetic coma. Cancer was remarkably rare as a cause of death among diabetics. An editorial in *Ugeskrift for Laeger* for May 1 suggests that the rarity of cancer in general, and cancer of the stomach in particular, in diabetics may be more apparent than real and that the malnutrition induced by cancer renders the milder forms of diabetes so free from manifestations of this disease that it is often overlooked by a physician when writing a death certificate. The same editorial comments also on the high death rate from hypertension and arteriosclerosis among diabetics. It is intimated that if these diseases of the arterial system can be prevented by dietetic measures not only diabetics but the community as a whole will be benefited

Progress in the Treatment of Poisoning by Hypnotics.—Since World War II the progress made in the treatment of poisoning by hypnotics deserves to be called revolutionary. The milestones marking this progress begin in 1946, when Kirkegaard showed the value of combating shock. In 1947 Lous and others demonstrated the importance of keeping the respiratory passages open and providing an uninterrupted supply of oxygen. The year 1949 is notable for the centralization in Copenhagen of these patients in hospital departments specially equipped and staffed for the purpose, a reform associated with the names of Clemmesen and Bie. In 1950 Eric Nilsson did much to discredit the treatment of these patients by stimulants. Dr. Carl Clemmesen and Dr. Marie Lindhardt of the medical statistical department of the Danish Public Health Service have now succeeded in presenting statistical evidence indicative of the improvements effected by these reforms. In the six year period 1945-1950 the number of victims of poisoning by hypnotics, chiefly the barbiturates, treated in hospital has more than doubled, with 1,509 in 1945 as compared with 3,051 in 1950. At the same time the death rate among these hospitalized patients has fallen from 24.5% in 1945 to only 6% in 1950. A classification of the patients according to whether they were treated in Copenhagen, with its new system of centralization, or elsewhere in Denmark shows that the death rate was only 3.4% in Copenhagen as compared with 8.2% in the rest of Denmark. Though the figures are not yet fully worked out for 1951, it looks as if the death rate for Copenhagen will be still further reduced to about 1.5%. It is probable that the example set by Copenhagen in the treatment of these cases will be followed elsewhere in Denmark.

The many articles dealing with barbiturate and allied poisonings recently published in the Danish medical press emphasize the scope and importance of this problem. The author of one editorial on the subject writes: "Why has there been such a widespread need for hypnotics and sedatives in the Danish population during these years? Has this need always existed? And is it only now gratified as a result of social progress and increased opportunities for taking medicines? Or is the atmosphere at the present time in Denmark such that constantly growing sections of the community must have drugs which can relieve insomnia, tension and restlessness?" Whatever the answer, it is at least a consolation to know that Denmark is doing pioneer work in this field with special reference to reducing the number of fatalities.

Death of Dr. H. J. Schou.—Dr. Hans Jacob Schou, who was born on Aug. 20, 1886, died on May 2, 1952, after a long illness. He came into prominence in 1921 on the death of Adolf Sell, the founder of the Filadelfia Colony for mental cases. Sell's work had been characterized by deep religious convictions and a genius for getting other persons to help him in his creativ efforts. But he was no scientist, and his colony was sadly i need of administrative reforms. Schou was appointed as his suc cessor in the hope that Sell's religious influence would not onl be perpetuated but also supplemented by administrative talen Since 1921 Schou has converted Filadelfia into a model of i kind for the whole of Denmark. The administrative talent hop of him developed most successfully, and his scientific bent l to the issuance of several important contributions to psychiat by his assistants. In 1928 Schou founded the first sanatoriu of its kind in Denmark for nervous or borderline mental cas Dianalund Nervesanatorium. Meanwhile, at the Filadelfia C ony he founded a special department for patients with epilep guiding its evolution so that it ultimately came to be a m or less independent unit under a medical officer of its own. was the "nervesanatorium" type of institution such as Dia lund that appealed most strongly to Schou, and he was tirel in his efforts to create a similar institution in Jutland. His p health did not prevent his enormous output of literary wo both scientific and popular. Even after his retirement in 1951, because of ill health, his literary activities continued. Among his later works, published in 1945, were his studies of the physiology of the manic depressive psychoses. His popular works often reflected his religious convictions, which showed no special preference for any one particular version of the Christian creed.

SWEDEN

Prevention of Tuberculosis in Schools.—A motion, addressed in 1952 to the Swedish Parliament, draws attention to an anomalous state of affairs with regard to the prevention of infection of schoolchildren by their teachers. The inmates in "day-homes" are carefully shielded by the law in this respect. Anyone employed in such institutions, even when the employment is of a temporary character, must be able to present a certificate that his or her lungs have been radiologically examined. Such workers are also kept under continuous supervision with the possibility of tuberculosis always in mind. A much less satisfactory state of affairs exists with regard to older children attending school. School medical officers are expected to take the necessary measures for preventing infectious diseases among teachers and other school personnel, and schoolchildren are kept under constant medical supervision throughout their scholastic careers; but legislation does not provide for the systematic medical control of the school staff by radiological examinations.

Between 1944 and 1946 as many as 65 cases of tuberculosis occurred among schoolteachers. In 1943 a manual training teacher infected eight boys between the ages of 12 and 14, and in 1945 a substitute teacher in less than three months infected another teacher and 16 scholars. After giving further evidence of school infections, the authors of this motion recommend that throughout their careers teachers should be obliged to undergo periodic radiological examinations at least every other year and preferably every year, with even more frequent examinations when special conditions call for them.

Barbiturate Poisoning.—At the Southern Hospital (Södersjukhuset) in Stockholm, Dr. C. M. Ideström and Dr. G. von Reis have undertaken an analysis of the 350 cases of barbiturate poisoning admitted during the period 1946-1950. There was a remarkable rise in the number of such cases for so short a period, from 42 admitted in 1946 to 120 in 1950. There was little change during the same period in the ratio of severe to light cases, about 50% of the patients being unconscious on admission. The reasons for the attempted poisonings were different for men and women, the most common reason for women being marital conflicts and love affairs, while depression was the most common reason for men. Men were outnumbered by women in the ratio of 134 to 216. While the age distribution for men was fairly even between 20 and 60 years, most of the women were of child-bearing age, between 20 and 40 years. The death rate was 5.1% (18 deaths). As many as 14 of these 18 deaths were due to poisoning with barbiturates with a prolonged action. A useful aid to diagnosis was the spectrophotometric method for demonstrating barbiturates in the serum reported on in 1948 by Goldbaum and subsequently modified by Helldorff, Ideström, and von Reis in 1949.

Is Pharmacy to Be Nationalized?—A committee appointed to investigate the possibilities of state control of the sale of drugs in Sweden has issued a report with recommendations, which have been responded to by lively protests from several quarters. These recommendations have included far reaching standardizations of drugs, extensive inspection and control of the pharmaceutical industry, economies of administration with quite a considerable reduction of the number of employees, and an annual saving of millions of Swedish crowns. It is calculated by the committee that, had a state organization of pharmacy been in operation in 1949, an economy of some 10 million crowns could have been effected in this year. In criticism of the present system of private enterprise it is argued by the committee that it has little or no inducement to prevent the excessive consumption or misuse of drugs. It is also intimated that the cost of certain drugs is at present excessive. A scheme is proposed for the centralization of the dispensing of drugs figured in physicians' prescriptions.

In memoranda issued early in 1952, the Swedish Medical Association, the Swedish Ministry of Health, and the Central Committee of the Swedish Pharmaceutical Association have drawn attention to the many faults found in this committee report. The proposed standardization of drugs is regarded as too radical from the medical point of view to be satisfactory. Considerable progress has already been made and is still proceeding with the standardization of drugs under the present system. As for the alleged excessive consumption and misuse of drugs, it is intimated that this is largely a problem of public health and education of the public. As for the complaint that the cost of drugs is too high, it should be noted that many of the newest and most costly drugs are just those drugs that by their effectiveness are greatly reducing the duration and thereby the cost of treatment. A comparison of the cost of drugs in Sweden and various other countries is much in favor of the former. The Swedish Medical Association has some suggestions to make with regard to the revision of certain features of the present system. Among other things it suggests that pharmacists should no longer be under an obligation to sell homeopathic drugs whose distribution to the public should be free. It is also recommended that the teaching of pharmacology should be deferred to a later stage in the medical curriculum than is the case at present. Such teaching should then include information on the economy of drugs. It is also proposed that the "Swedish Pharmaconomia" should be issued free of charge to the medical profession at short intervals.

TURKEY

Chloroma of the Eye.—Dr. Nuri Fehmi Ayberk, director of Istanbul-Haidar Pasha General Hospital and chief of the department of ophthalmology, presented a case of chloroma before the Turkish Ophthalmologic Society. Thirty-five days prior to admission, the patient, a boy, aged 8, had been ill with a fever for eight days. He had a severe headache, and gradually exophthalmos developed. After a week the temperature became normal, but exophthalmos, blurred vision, and general weakness remained. The family's and patient's histories were negative. He was pale and anemic, 140 cm. in height and 28 kg. in weight; both eyes had the same degree of exophthalmos, the eye movements were limited and irreducible, and there was no diplopia. Fundus examination revealed a colorless pupil, narrow arteries, no hemorrhage, vision 8/10, normal eye pressure, and a free field of vision. The patient had lymph nodules under the chin, under both ears, and in the groins, and none under the armpits; the spleen and liver were slightly enlarged. The red blood cell count was 1,300,000, the white blood cell count 172,000, and the hemoglobin value was 20%. The differential study of the white blood cells showed 75% myeloblasts, 13 adult eosinophils, 8 transitional mononuclears, 3.75 large mononuclears, 2.25 normoblasts, 0.25 myelocytes, 0.75 myelocyte eosinophils, 0.25 macroblasts, 0.25 erythroblasts, 0.25 lymphocytes, 0.25 histocytes, 0.25 plasmocytes, and 0.50 basophil normoblasts. Wassermann, Kahn, Weinberg's, and Casoni's tests were negative, and the Takata-Ara test was 5 to 8 positive. The rate of sedimentation after half an hour was 12 mm., after 1 hour 40 mm., after 2 hours 125 mm., and after 24 hours 175 mm. X-ray examination revealed no lesions in bones or sella turcica, head, and face bones. The right lung showed hilitis. The patient was given penicillin, streptomycin, urethan, nitrogen, and blood transfusion; the temperature decreased, and there was a slight improvement. The patient died after six weeks. Necroscopy revealed that chloroma had caused metastasis in the brain, orbits of the eyes, lungs, testicles, and lymph nodules. In the United States leukemia has been treated successfully with aminopterin (4-aminopteroylglutamic acid), but this new drug has not entered Turkey yet. Only about 150 cases of chloroma have been reported in world medical literature. The first three cases of chloroma in Turkey were reported by Dr. Shükrü Hazim Tiner, Prof. Muzaffer Güçhan, and Prof. Naci Bengisu.

CORRESPONDENCE

CARCINOMA IN SITU

To the Editor:—Since the introduction of cytodiagnosis, carcinoma in situ has become recognized as a neoplasm of surprising frequency. Since the lesion is often found in cervical tissues that appear normal, one of the significant problems has been to secure biopsy confirmation of these lesions following initial detection with cytology. The absence of a target lesion for biopsy has indicated the need for a "ring biopsy" if histological study is to be accurate. Considerable mystery surrounds this so-called embryo cancer, since numerous reports have appeared in the literature indicating apparent spontaneous regression, especially during or following pregnancy.

In an effort to secure a comprehensive expression of authoritative medical opinion concerning its character, the Dade County Cancer Institute recently prepared a questionnaire on carcinoma in situ that was mailed to leading authorities in the fields of gynecology, pathology, and cytology. Replies were received from members of the American Gynecological Society, the South Atlantic Association of Obstetricians and Gynecologists, the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, and from many cytologists and pathologists whose names have appeared prominently in the scientific literature dealing with carcinoma in situ. A total of 160 opinions are represented by the report.

A summation of the results of the questionnaire was presented at a recent two day conference on carcinoma in situ conducted by the Cancer Cytology Center, Dade County Cancer Institute. Participating in this program were various authorities in this field, including Dr. F. Bayard Carter of Duke University; Dr. Edgar R. Pund, Medical College of Georgia; Dr. John E. Dunn of the Field Investigation Section, Cancer Control Division, National Cancer Institute; Dr. Joseph K. Cline of the University of Alabama, Department of Cancer Research; Dr. Lyndon E. Lee, Director of Cancer Control in Puerto Rico; and Lieut. John T. Rogers, U. S. Naval Hospital, St. Albans, N. Y., in addition to the writers of this letter.

The following conclusions, based on the questionnaire on carcinoma in situ, came out of the conference.

What Is Agreed.—There is general agreement that: 1. Cancer in situ is stage 0 cervical cancer (international classification). 2. Cancer in situ is a preinvasive stage of genuine cervical carcinoma. 3. Routine cytological study is the detection method of choice, to be confirmed later by biopsy. 4. The biopsy method of choice in common use at present is either the mutiple punch or the "ring biopsy" technique. Most replies agreed that single biopsies or random biopsies were inadequate for confirmation, since there was no "target" lesion. 5. Repeated positive results of cytological tests with repeated negative results of biopsy do not rule out carcinoma. More adequate histological studies are indicated under these conditions. 6. Total hysterectomy is adequate therapy and is the treatment of choice in most clinics. A significant group, including many of those representing university teaching centers, favored treatment depending on age, emphasizing more conservative therapy (ring biopsy and electroconization or amputation of the cervix) in the reproductive age group. 7. Claims of spontaneous regression after biopsy may be fallacious. It was the general opinion that biopsy, to be adequate in this "preclinical" stage of neoplasm, may frequently extirpate the entire lesion or in other cases be followed by sloughing of the residual anaplastic tissues. Out of 141 observers, 138 stated they could not eliminate the possibility that biopsy might have removed the entire lesion. Therefore, adequate biopsy invalidates study of the behavior of carcinoma in situ. 8. There is no evidence of metastasis to lymph nodes from carcinoma in situ (when invasion has been definitely ruled out by adequate histological study).

What Is Controversial.—Controversy exists regarding: 1. Spontaneous regression. Most investigators have never observed spontaneous regression in their personal experiences, but 31 believe that it may occur. Fifteen observers reported regression in one or two cases, and six had observed it in three or more cases. 2. Tissue diagnosis of carcinoma in situ during pregnancy is equivocal; 50 would accept it, 64 would not, 34 were uncertain, and 16 preferred to confirm after delivery. 3. In reply to the question "Should in situ cancer be studied by frequently repeated (serial) cytology, surgery withheld?" 70 answered yes, in order to determine behavior and prove or disprove regression; 76 were not in favor; 8 were agreeable to such a course of action during pregnancy; 2 were uncertain; and 4 believed that such cases should be followed with further cytological studies and biopsy.

The nature of cervical carcinoma in situ is receiving critical scrutiny by the medical profession at the present time. This report provides a cross section of authoritative opinions concerning what factors are agreed on and those that remain controversial. Much further clinical research remains to be conducted before the true character of this provocative growth entity will be revealed.

In our opinion, the "surface biopsy" cell scraping provides the simplest, most accurate, and least expensive method for detection of cancer in situ or preclinical invasive cancer. In practice, all positive cytological diagnoses should be confirmed by adequate biopsy before treatment. Apparently, it will be necessary to perform periodic cytological studies for long periods on selected patients with carcinoma in situ to determine the true frequency of spontaneous regression and of progression to invasive cancer.

TICKS FOR STUDY OF TICK PARALYSIS

To the Editor:—I would be very grateful if you would inform your readers that I am anxious to study ticks removed from tick paralysis patients. However, I must have live ticks.

Tick paralysis may not be the result of an infectious agent. The rarity of paralysis following the engorgement of the tick suggests that the ticks responsible must be exceptional and capable of introducing a very potent neurotoxin. I should gladly pay all expenses concerned and suggest that living ticks, even though damaged by removal, be sent by air mail. The ticks should be placed in an airtight, clean, 1 oz. ointment tin, in which a disc of filter paper moistened with one drop of water is placed. The tin containing the ticks should be enclosed in the ordinary mailing tube used for sending fragile materials and sent to me at the address below.

EMERGENCY MEDICAL CALL SERVICES

To the Editor:—During the meeting of the American Medical Association in June, 1951, the House of Delegates adopted a resolution which requested all national specialty boards to facilitate general participation of specialists in emergency medical call services. These boards were asked to assure diplomates and potential diplomates that participation in such a community activity would not jeopardize specialty ratings. This resolution was adopted in response to a report of the Council on Medical Education and Hospitals of the American Medical Association and was approved by the Advisory Board for Medical Specialties on Feb. 10, 1952. The American Board of Proctology approves of this plan and wishes all of its diplomates and potential diplomates to know that their "specialty ratings" will not be jeopardized by participation in this worthy community activity.

SKIN SCRAPINGS IN LEPROSY

To the Editor:—The clinical note in The Journal, Jan. 5, page 44, by Dr. R. K. Maddock, entitled: "Skin Scrapings in Leprosy; Positive Results by the Wayson Technique in Eighty-Four Supposedly Arrested Cases," is, I fear, likely to cause some confusion in the literature. Leprosy workers who see the title will wish to learn of this supposedly improved technique of obtaining material for bacteriological smears. Actually it is the long-established and widely-used "scraped-incision" method, with nothing new except the insistence that the cut be made through the full thickness of the skin; and the advantage of that, if any, is offset by the facts that, apparently, the incision is scraped only once and only one lesion or lesion-site is examined.

Dr. Maddock referred to the technique he described as the "snip" method. That method, however, long used in certain quarters, involves removal of a shallow piece of the skin by curved-on-flat scissors. The raw surface of the bit removed is then rubbed on the slide or scraped with a scalpel to obtain pulp. This technique has long since been abandoned.

The scraped-incision method was introduced by me in the official leprosy examining committee in Manila when I became chairman in 1917-1918, to replace the previously used puncture method by which the main element obtained was blood, exuded or expressed. In examining smears of that material much time was wasted, and, undoubtedly, not a few cases were erroneously reported as negative. The new method has been described repeatedly, first in an article entitled "A Plea for the Early Recognition of Leprosy, with Notes on Diagnosis and Methods," by H. W. Wade and C. B. Lara (*J. Philippine Islands M. A.* 4:132-140, 1924) and most recently by me—because of practices observed during a world tour of leprosy institutions—in a detailed and illustrated article, "The Bacteriological Examination in Leprosy" (*Leprosy Review* 6:54-60, 1935). The latter article was quoted by R. G. Cochrane in his "Practical Textbook of Leprosy" (New York, Oxford University Press, 1947, pp. 68-69), photographs being used to illustrate certain points, including the depth of the incision.

The more important features of the technique, as stated in the first description are (*a*) making an actual cut, "deep into the skin," with a sharp-pointed, keen-edged instrument, a small (short-bladed) scalpel being preferred, although a razor blade or other instrument might be used, and (*b*) getting tissue juice and pulp by scraping the wall of the incision, measures being taken by compression and otherwise to avoid or minimize dilution with blood. This method cannot properly be dismissed as one obtaining material "only from the superficial layers" of the skin, although that would apply to the real snip method. Emphasis was given to the (usual) necessity of making multiple smears. In practice four to six or more are usually made from different sites, including the nasal mucosa on both sides.

That the cut should be "through the full thickness of the skin" is, in my opinion, neither necessary nor desirable. Nor is a single scrape of the blade always sufficient, because, in many instances, in both the lesions of patients with the macular cases coming for diagnosis and in thoroughly resolved lesion-areas of candidates for parole, the tissue is relatively firm and tough, and repeated scraping is required to obtain any material amount of pulp.

Few leprosy institutions could afford to use a new slide for every examination, and there is no need of it whatever if elementary care is exercised in cleansing used slides. Dr. Maddock does not say whether the razor blade, once used, is discarded, but presumably it is. At Carville, where I have watched that implement being used and have tried it myself, a new one is used for each smear. In few places could that be done, because of the expense, especially if multiple smears were made at each examination as they should be. Personally, I do not like that instrument, for it is not so easily controlled as is a suitable short scalpel, and the straight edge is not so well suited as a bellied one for obtaining pulp from the cut surface. It could not, of course, be used for the nasal mucosa.

The experience related by Dr. Maddock is paralleled in a way by that of the late Dr. E. V. Pineda, who for several years was my first assistant in the laboratory here when I was in the government service, and who in 1927 or 1928 left to take charge of the leprosy department of the San Lazaro Hospital in Manila. Two or three years later he found himself in difficulties with his patients and otherwise, it being held that he was not so successful in treatment as his predecessor had been. The latter, who supposedly had been using our standard method in making bacteriological examinations but actually had not, was discharging about 100 patients a year as having negative tests. Dr. Pineda, using the method of examination I had introduced at Culion—properly taken smears from multiple sites—was able to discharge under the regulations only about 25 a year.

PRECAUTIONS IN AUTOPSY AND EMBALMING PROCEDURES FOLLOWING THE ADMINISTRATION OF RADIOISOTOPES

To the Editor:—As administration of radioisotope therapy is becoming widespread, problems arise concerning the handling of postmortem tissues, which, because of antemortem high dosages of certain radioisotopes, may emit radioactivity for some time after death. This notice is designed to disseminate recommendations regarding precautions to be taken in the handling of radioactive tissues during postmortem examination or in embalming procedures.

An up-to-date list of all patients who have received radioisotopes should be maintained in the record office of hospitals. This information should be supplied by the radioisotope laboratory. Names of all deceased persons should be checked against this list by the record office personnel. If the deceased has ever received isotopes, the person in charge of the radioisotope laboratory should be promptly notified.

If the deceased has received a therapeutic isotope dose within two months, the radioactivity survey officer should monitor the body before autopsy or release to a mortician. If an autopsy is to be performed, the record office should inform the pathologist who is to perform the autopsy that radioisotopes have been given. The pathologist should secure from the radioactivity survey officer a report of the amount of radioactivity, and copies should be attached to the autopsy protocol and the clinical chart.

The precautions to be taken will depend on the level of radioactivity found by the radioactivity survey officer. In cases in which the level is less than one-half milliroentgen per hour (mr/hr.), no special precautions are necessary at any time. In cases in which the level is from ½ to 6 mr/hr., the only precaution necessary in handling the body would be the wearing of rubber gloves, which should be washed with soap and water before they are removed from the hands. When the level is over 6 mr/hr. further precautions are necessary in order that the maximum permissible exposure of 0.3 r per week shall not be exceeded. The additional precautions in such cases should be (1) the wearing of a lead apron and a dosimeter; (2) thorough cleansing with soap and water or detergent of tables and other surfaces on which blood or other body fluids have been spilled; and (3) the avoidance of eating and smoking while wearing the rubber gloves.

In all cases in which the level of radioactivity is over ½ mr, every effort should be made to confine body fluids that are removed during the course of the postmortem procedures to special vessels, to pour them directly into the drain, and to flush copiously with water. In cases in which it is desired that organs or body fluids be retained for further study, they should be kept in special containers and suitably labeled. As the radioactivity decreases rather rapidly, these materials could be retained until their level of radioactivity has fallen below the danger level as determined by radioactivity survey; otherwise, the precautions as noted herein should be carried out.

The mortician should be given instructions similar to those for the pathologist, the nature of which will depend on the degree of radioactivity remaining at the time of delivery of the body to the mortician. The precautions herein outlined were approved by the Division of Biology and Medicine of the United States Atomic Energy Commission.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Permanence of Cinnamon Sensitivity.—The claimant sought a compensation award for permanent disability resulting from his sensitivity to cinnamon. From a denial of such award the claimant appealed to the district court of appeals, first district, division 1, California.

The claimant had worked as a baker since 1922, during which time he handled cinnamon without harmful results. In November, 1948, he was employed by Masonic Homes as a pastry baker. The following February a rash developed on his hands; it became so acute that he quit work on March 10, 1949. The commission determined that he had contracted a disabling dermatitis, which was caused by sensitivity to cinnamon and gave him temporary total compensation. The condition disappeared in April, and he went to work as a baker for another employer. After three days the condition reappeared, and a few days later he was forced to quit. After a short period of rest the condition disappeared. Twice later he went to work for other employers, and after extremely short periods of employment he again broke out with dermatitis due to his sensitivity to and contact with cinnamon. Each time he received total compensation, and each time his dermatitis cleared on cessation of contact with cinnamon and reappeared on subsequent exposure. He then filed his petition for a permanent disability rating. At the hearing before the commissioner the claimant submitted the reports of five physicians, one of whom was his personal physician. All agreed substantially that at the present time he is sensitive to cinnamon and that exposure to it produces dermatitis. None of the physicians other than his own reported on the permanency of this sensitivity. The only medical evidence in the record is the following report of his personal physician: "Because this skin test is still positive to cinnamon, the patient would still be unable to work as a baker without having a recurrence of his skin eruption as long as he contacts cinnamon. This skin sensitivity to cinnamon will probably remain for an indefinite period of time, but it is impossible to know how long such a sensitivity will remain." On the basis of this evidence the claimant contended on appeal that the commissioner erred in finding that the claimant suffered no permanent disability.

After pointing out that whether the injury was permanent at a particular time was purely a question of fact and that the burden of proof was on the claimant to show that his sensitivity to cinnamon was permanent, the court of appeals said that it was a fact that on four different occasions since 1949, when exposed to cinnamon, dermatitis developed, and all the physicians agreed that the claimant is now sensitive to cinnamon, and exposure to it at present will result in dermatitis. These facts alone, continued the court, do not establish that such condition will continue for the balance of his life or meet the test of permanent disability. A disability is generally regarded as permanent when further change, for better or worse, is not to be reasonably anticipated under usual medical standards. It may be that no further treatment is possible or that the only treatment suggested is so problematical of success that the employee's refusal to undergo it is warranted. In such an event, it is permanent within the meaning of the act. In practical legal results, the healing period is over, and a permanent aftermath of disability exists. Ordinarily, the term permanent, when applied to a personal injury, means "lasting during the future life of the injured party." The evidence on which the claimant relies, said the court, is the statement of his personal physician that the "sensitivity to cinnamon will probably remain for an indefinite period of time but it is impossible to know how long such a sensitivity will remain." This is not a prognosis that it will remain all his life or will be permanent. The most that can be said of the statement is that it is susceptible of two reasonable inferences, one that it might continue for his lifetime, the other that it might not so continue. The commission adopted the second inference. The physician's statement in no wise compels the adoption of the first inference. Certainly the statement of the physician that it is impossible to know how long the sensitivity will continue is not sufficient to compel the conclusion that it is a permanent condition. Accordingly, the court of appeals affirmed the denial of an award by the compensation commissioner. *Sweeney v. Industrial Accident Commission, 236 P. (2d) 651 (California 1951).*

Medical Practice Acts: Revocation of License for Income Tax Evasion.—The defendant Raab had engaged in the duly licensed practice of medicine in Ohio for several years when he was convicted of income tax evasion under the federal statutes and served a sentence of 18 months in a federal penitentiary. Subsequent to the serving of that sentence, the state medical board of Ohio revoked Raab's license to practice medicine on the ground that he had been guilty of a felony, that being a ground for such revocation under the medical practice act. On appeal to the court of common pleas, the action of the state medical board was reversed, so the board appealed to the Supreme Court of Ohio.

The controlling question, said the Supreme Court, is whether conviction of violation of a federal statute that carries the penalty of imprisonment in a federal penitentiary constitutes the practitioner "guilty of felony" within the meaning of the medical practice act and is thus a valid ground for revocation of his license to practice medicine. The term "felony" is not defined in the medical practice act but is defined in the Ohio general code, which provides: "Offenses which may be punished by death, or by imprisonment in the penitentiary, are felonies. . . ." It was argued on behalf of Raab that "felony" as used in the general code included only a violation of the criminal statutes of Ohio and that the criminal charge must be based on the Ohio statutes. In support of this position it was claimed that the legislature evidenced intent to confine the term "felony" to violations of Ohio statutes by failing to specifically state in either the medical practice act or the general code that violation of any statute, other than a statute of Ohio, could constitute a felony. On the other hand, the state medical board contended that the term "felony" as used in the general code included a violation of any federal statute that is punishable by imprisonment in a federal penitentiary.

In the case now under consideration, said the court, the crime consisted of a violation of a law of the United States. Citizens and residents of Ohio, as they go about their daily work or pursue their professions, are subject to the laws of the United States as well as the laws of Ohio. They are protected by both and must pay the penalty for violation of either. The operation of the federal courts in Ohio is necessary for the good of Ohio citizens. The enforcement of federal statutes in Ohio is as necessary as the enforcement of Ohio statutes. No one would deny that every Ohio citizen is amenable to the federal income tax laws. We, therefore, consider it reasonable to conclude, said the Supreme Court, that the General Assembly of Ohio had in mind this dual obligation of Ohio citizens when it enacted its general code. We are of the opinion that the term "felony," as used in that section, includes a violation of a federal as well as an Ohio criminal statute, the penalty for which violation is imprisonment in either a federal or the state penitentiary. Conviction of a violation of a federal statute punishable by imprisonment in a federal penitentiary satisfies the requirement of the general code. Accordingly, the judgment of the trial court was reversed and the order of the state medical board revoking Raab's license to practice medicine was affirmed. *In re Raab, State Medical Board of Ohio v. Raab, 101 N. E. (2d) 294 (Ohio 1951).*

Skin Resistance in Absence of Sweat Glands.—A 43-year-old woman and her 10-year-old daughter who had the rare anhidrotic type of hereditary ectodermal dysplasia were studied with regard to their sweating. Electrical skin resistance studies revealed areas of high resistance over the entire body except the axillas, palms, and soles. On the face and upper chest the resistance was high but relatively lower than over the remainder of the body surface. Chemical tests for sweat and biopsies confirmed the absence of sweating in the areas demarcated by the electrical skin resistance studies. Galvanic skin responses were absent from nonsweating palmar areas, and were present, but very weak, in sweating palmar areas. These findings support the concept that electrical skin resistance is inversely related to sweat gland activity, rather than to vasomotor activity or other changes accompanying sympathetic nervous system activity. The electrical resistance of the skin in the areas where sweat glands are congenitally absent is as high as that observed in denervated or sympathectomized areas of the body in normal persons. In areas where sweat glands are present, the electrical resistance is dramatically lower, and is inversely proportional to environmental temperature and consequent sweat gland activity.

Pre-Lupus-Erythematosus (L. E.) Cell.—In six of seven patients with acute disseminated lupus erythematosus, the L. E. phenomenon, i. e., the presence of L. E. cells and/or rosette formation, was demonstrated on admission examination. In the seventh patient this finding was not revealed on first examination despite a characteristic clinical picture of acute disseminated lupus erythematosus, which responded dramatically to treatment with cortisone. A pronounced clinical relapse after discontinuation of this drug brought the patient back to the hospital six weeks later, and this time typical L. E. cells and rosette formation were observed. In addition the following changes in the polymorphonuclear cells were seen, which were interpreted as stages in the development of the L. E. cell: (1) pyknosis of one or more nuclear lobes, (2) pyknosis of all nuclear lobes and rounding of one or more lobes with preservation of intact interlobar filaments, (3) disappearance of interlobar filaments leaving cells containing one to five round homogenous masses of nuclear material but with normal cytoplasm and granules (the pre-L. E. cell), (4) partial extrusion of round nuclear masses from the cells, (5) presence of free nuclear material outside cells, and (6) phagocytosis of nuclear material by other polymorphonuclears to form L. E. cells. The pre-L. E. cell is the distinctive stage in this process in which the destroyed fragments of nuclear origin are still within their own cell boundaries. Recognition of the pre-L. E. cell may help in the early diagnosis of disseminated lupus erythematosus.

Intracranial Hemorrhage and Aneurysms.—Dekaban and McEachern selected 143 cases from the records of the Montreal Neurological Institute for analysis of the relation of spontaneous subarachnoid hemorrhage, intracerebral hemorrhage, and intracranial aneurysm. These cases were observed from 1938 to 1948. The criteria for selection were as follows: 1. The condition had to be proved by lumbar puncture, arteriogram, operation or autopsy. 2. The hemorrhage must have occurred within four days prior to admission. 3. The hemorrhage must not have been due to trauma. There were 30 cases of ruptured aneurysm, 8 cases of nonruptured intracranial aneurysm, 13 cases of abnormal arteriovenous communication, 1 case of subarachnoid hemorrhage with proved rupture of anatomically normal artery, 56 cases of subarachnoid hemorrhage of undetermined cause, and 35 cases of primary intracerebral hemorrhage. The authors stress that blood in the subarachnoid space, in addition to raising the intracranial pressure, acts as an irritant, causing general systemic and local meningeal reactions. The latter, in some cases, are severe, with as many as 4,000 white blood cells per cubic millimeter of cerebrospinal fluid. Aseptic meningitis, or even constitutional fever, may be suspected wrongly in the mild cases unless lumbar puncture is carried out. The meninges show cellular infiltration and phagocytosis in the acute stage, followed later by patchy fibrosis. This distribution may explain the infrequent occurrence of hydrocephalus in surviving patients. Ruptured aneurysm was found to be responsible for the subarachnoid hemorrhage in nearly all cases in which autopsy was performed. Twenty-six of 30 ruptured aneurysms were of the congenital, berry type; the remaining 4 were fusiform and of arteriosclerotic origin. Because of the frequent occurrence of multiple and bi-

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

lateral aneurysms, the necessity of bilateral angiography is stressed. The majority of patients with spontaneous subarachnoid hemorrhage recover without surgical treatment; in some patients the risk of repeated bleeding may be abolished by intracranial clipping and excision of an aneurysm. The possibility of blood dyscrasia and an abnormal bleeding tendency should be kept in mind in all cases of subarachnoid hemorrhage, and appropriate treatment should be carried out with rutin, ascorbic acid, and vitamin K.

Injection Schedules for Early Syphilis Treatment.—Of 146 patients with darkfield-positive secondary syphilis 60 were given 2,400,000 units of procaine penicillin G in peanut oil with 2% aluminum monostearate in a single administration of 600,000 units at each of four sites, while 86 patients were given 2,400,000 units of the same penicillin preparation in two administrations of 1,200,000 units, 96 hours apart. After 12 to 15 months there were 88.2% successes, 3.6% reinfections, and 8.2% failures in the group receiving one injection, and 89.5% successes, 2.5% reinfections, and 8% failures in the group receiving two injections. Surface spirochetes and syphilitic lesions showed a response similar to that obtained with aqueous penicillin or trivalent arsenicals. No serious reactions were noted. Comparisons of penicillin blood levels during the one and two injection schedules revealed a much higher average peak concentration as well as a slightly greater area under the curve for the one injection schedule. No penicillin activity was observed in samples of cerebrospinal fluid drawn from patients during a 24 hour period following a single injection. Eleven patients from the one injection group and 11 patients in the two injection group became pregnant after treatment and were not retreated. Eight babies were born alive in each group. All of the 16 infants who were born alive were clinically, serologically, and roentgenologically negative for syphilis 1 to 14 months after birth. Three fetal deaths occurred in each of the two groups. The clinical evidence suggests that the one and two injection schedules were equally effective in treatment of early syphilis. On one of two other schedules aqueous crystalline penicillin G was injected intramuscularly every three hours in doses totalling 2,400,000 units over seven and a half days, and on the other 600,000 units of penicillin in peanut oil and beeswax were injected daily for eight days in total doses of 4,800,000 units. Comparison of all four methods revealed that the one injection schedule is as effective as the others. Its main advantage is that treatment, exclusive of follow-up, can be accomplished in one visit to the clinic.

Chloramphenicol in Treatment of Venereal Diseases.—Chloamphenicol (chloromycetin®) was given intramuscularly in a single dose of 1 gm. to 51 patients with gonorrheal urethritis. Of the 51 patients, 36 returned for at least one post-treatment examination, and 31 of these were cured. If the two patients who admitted exposure after treatment are considered reinfections rather than failures, the cure rate is 92%. The authors feel that chloramphenicol is probably as effective as penicillin. Seven Negro patients with granuloma inguinale were treated with chloramphenicol intramuscularly in doses of 1 to 2 gm. daily for 9 to 15 days, with total doses of 10 to 18 gm. In all seven patients the lesions healed rapidly. In three patients there was noted an extraordinarily rapid return of pigment in the lesions. Final evaluation of treatment of granuloma inguinale with chloramphenicol must await a larger series of patients and longer follow-up periods.

Chloramphenicol and Penicillin in Urethritis.—Of 313 male patients with acute gonorrheal urethritis, 192 were given a single intramuscular injection of 900,000 units of procaine penicillin G in oil with 2% aluminum monostearate, and 121 patients received a single oral dose of 3 gm. of chloramphenicol (chloromycetin®). Penicillin proved to be curative in 165 patients who could be followed up to the 23d post-treatment day, and chloramphenicol proved curative in 103 patients who were followed for the same post-treatment period. There were no untoward reactions to the penicillin treatment. The single dose of 3 gm. of chloramphenicol was well tolerated; mild side-effects were bitter taste persisting for two to six hours, noted by 50% of the patients, and a mild transitory diarrhea, noted by 5%. Both penicillin and chloramphenicol in single doses in the amounts used by the authors are effective enough in treatment of acute male gonorrheal urethritis so that measures to insure the return of patients who lapse during the post-treatment follow-up period can be eliminated with no appreciable loss of efficiency in the gonorrhea control program. Epidemiological control efforts should stress the bringing of sexual contacts of newly diagnosed cases to medical supervision to eliminate potential new foci of infection as rapidly as possible. The single dosages used may be sufficient to abort syphilitic infection acquired at the same time as the gonorrhea. However, until such time as further data are available on this point, routine serologic tests for syphilis should be done on all patients treated for gonorrhea, both at the time of diagnosis and three to six months after treatment.

Anal Irritation Following Use of Antibiotics.—An epidemic of influenza presented an opportunity to observe certain proctologic sequelae in 21 patients who had been treated with aureomycin or similar antibiotics. These effects became manifest from four weeks to eight weeks after administration of the drug, so that the relationship frequently was unrecognized. A variety of ointments and other therapeutic measures had been used with little or no relief. The major symptom was itching and burning about the anus, which at first was intermittent but later became continuous. Defecation aggravated the distress. The perianal skin was a dusky red, with scattered rosy follicles and many erosions. Scales, crusts and excoriations from scratching were present in some patients. The process often involved the anal canal. The crypts were sometimes reddened, and in several patients the papillae were cherry-red. Some patients had a low-grade proctitis. The cause of this anorectal disorder is not definitely known, but there has been speculation on possible changes in the intestinal flora due to selective suppression of the normal bacteria by the antibiotic, with consequent changes in the pH of the feces or chemical constituents of cholinogenic or steroid origin. Interference with vitamin B complex absorption has been suggested as a possible cause. The following treatment was found helpful: The perianal skin was shaved, then sprayed with a 2% solution of tetracaine (pontocaine®). Tincture of benzoin was applied and allowed to dry. Zinc oxide (Lassar's) paste was then spread thinly over the area. This procedure was repeated twice weekly until the lesions cleared. While local anesthetic ointments may give temporary relief, they often tend to aggravate the irritation or cause violent local reactions.

•Analysis of 240 Cases of Cancer of Larynx, with Respect to Terminal Phases and Death. P. D. Latella.—p. 266.

Acoustic Trauma in Children.—The histories of three children referred by a school nurse to a hearing test center during the past year indicate that more attention should be given to the effect of loud noises on the hearing acuity of children. In all three children, permanent hearing defects were produced by inadvertent exposures to cap pistols or fire crackers. The deafness was of the nerve type, and was similar to that encountered among military personnel exposed to gunfire. The detection of these cases of hearing loss was made possible by carefully testing each subject in a quiet room with frequencies of 500, 2,000, 4,000 and 8,000 vibrations per second, at 15 decibels and utilizing principles of audiometry. Physical and otological examination of all three patients revealed that the membrana tympani and middle ears were normal, and there was no evidence of adenoid hypertrophy in the nasopharynx. While these cases are too few to draw any definite conclusions, it seems obvious that the possibility of acoustic trauma in children deserves more attention. The hearing defects resulting from acoustic trauma in these patients are probably not progressive.

Terminal Phases of Cancer of Larynx.—In order to determine the cause of death and terminal condition of patients with cancer of the larynx, Latella reviewed the records of 240 patients, of whom 117 had died and the remainder were in the terminal phases. He found that the cause of death and terminal phases of these patients are the same as of the patients who have cancer elsewhere in the body. Because the growth primarily involves the upper airway, one might conclude that laryngeal occlusion would be a usual cause of death, but this does not occur when tracheotomy is available. Hemorrhage as the cause of death occurred in only 16% of the patients, which is not as high as might be expected with a cancerous growth that can produce so much destruction and ulceration of such vascular areas as the larynx, the root of the tongue, and the neck. The laryngectomized patients were spared the foul-smelling, painful, ulcerating necrotic larynx so often seen in patients who were treated ineffectively with radiation. However, once neck metastases become progressive in a laryngectomized patient, the subsequent course is little different than in the nonoperated case. If the secondary neck metastasis has received ineffective radiation, the terminal phase is severer than if irradiation is not given. Bronchopneumonia is secondary to blocking of the tracheobronchial tree by accumulated secretions, vomitus, or blood. These patients have no terminal rise in temperature as with primary infections; they apparently drown in their own secretions. Only two patients out of 116 died of cardiac failure. Metastases to distant organs and involvement of heart, spleen, liver, and kidneys were infrequent. Malignant cachexia appeared as nutrition failed and pain, sleeplessness, and anxiety appeared, but it was not produced by toxins or poisons emitted by the growing tumor. Conscientious scientific nursing is of great importance. Knowledge of the final stages of laryngeal cancer will enable the physician to carry out a plan of treatment that will make the last days of these patients more bearable.

Cortisone in Shoulder Hand Syndrome.—The 71-year-old woman whose case is reported had a healed posterior myocardial infarct and diabetes mellitus. She complained of fatigability, exhaustion on walking, insomnia, and nocturia, recurring episodes of substernal distress, and tightness in the chest. An attack of left-sided hemiplegia largely subsided, but some weeks later she experienced an ache in her left shoulder, with limitation of motion because of increased pain. This became rapidly worse, and in about 7 to 10 days the hand and wrist were swollen, and the skin had a dusky cyanotic appearance. Movement of fingers, hand, and wrist became very painful. There was no evidence of rheumatoid arthritis. Treatment consisted of such physiotherapeutic procedures as paraffin baths, infrared ray therapy, and passive exercise. When these proved ineffective, she was given several nerve blocks plus local infiltration of trigger points, but relief was transient. Then she was given 100 mg. of cortisone daily by mouth. Within 48 hours improvement began. The pain subsided sufficiently so that administration of all narcotics was discontinued, and comfort was achieved with five grains (0.3 gm.) of acetylsalicylic acid given every three to four hours. After one week the swelling of her fingers, hand, and wrist subsided. The range of motion of the shoulder was increased without pain. The appetite was increased, and the mental depression and fatigue disappeared. When her blood sugar became elevated and glycosuria appeared, increased doses of insulin reestablished control. After 10 days of cortisone therapy, using 100 mg. daily, the dose was gradually reduced and then discontinued. The author recommends cortisone in the management of the shoulder hand syndrome.

Intra-Arterial Injection of Histamine in Peripheral Arterial Disease.—This paper reports the results obtained with intra-arterial injections of histamine in a small group of men with intermittent claudication, whose average age was 64 years. They had been under observation for several months, during which time Buerger's exercises, oral doses of priscoline® (2-benzyl-2-imidazoline hydrochloride), reduction in smoking, moderate doses of alcohol, foot hygiene and reflex heat had been used with little effect. The patients were taken to a constant temperature room and their skin temperature response in the lower extremities to immersion of the arms in hot water was measured. If the temperature in the affected leg did not rise significantly, a posterior tibial nerve block was performed and the temperature was again measured. Several patients were given a paravertebral block or spinal anesthetic as a further check. The histamine injections were given by means of the ordinary intravenous apparatus, plus a hand bulb to raise the pressure in the bottle, and 3 mg. of histamine diphosphate in 500 cc. of isotonic solution of sodium chloride were introduced into the femoral artery in about one-half hour. The usual schedule was two injections per week for the first three weeks, then one injection per week until the tolerance for walking appeared to be stabilized. Injections were then discontinued, and the patient's walking tolerance was checked at monthly intervals. If regression was noted, weekly injections were reinstituted. The walking tolerance was tested by means of a motor-driven continuous belt-type of treadmill. Five of seven patients treated by the intra-arterial injection of histamine diphosphate obtained favorable results, one fair, and one poor results. Improvement was usually evident by the sixth injection. The following changes occurred during the arterial infusion of histamine: increase in heart rate, stroke volume, cardiac output, skin temperature and oxygen saturation in the femoral vein, and decrease in blood pressure. These physiological changes are similar to those seen in association with arteriovenous shunts, and it is suggested that the beneficial effects of intra-arterial histamine may be due to acute arteriovenous shunting and subsequent improvement in the collateral arterial circulation.

Bishydroxycoumarin in Acute Myocardial Infarction.—Many physicians find it difficult to decide whether or not a patient sustaining a mild episode of acute myocardial infarction should be treated with anticoagulant drugs. The committee for the evaluation of anticoagulants in treatment of coronary occlusion with myocardial infarction of the American Heart Association has recommended the employment of such therapy in patients with this disease unless contraindications to anticoagulant therapy exist. However, an analysis of the mortality and incidence of thromboembolism in 1,047 cases of acute myocardial infarction treated conservatively shows no justification for the routine employment of bishydroxycoumarin (dicumarol®) in this disease. The death rate in 489 "good risk" cases in which anticoagulants were not given was only 3.1%, and the incidence of thromboembolism in the same group was only 0.8%. The mortality preventable with bishydroxycoumarin would have been, at most, only 1.0% in these selected cases. Since such small benefit is more than likely to be nullified or even overbalanced by complications induced by bishydroxycoumarin, the authors feel that anticoagulant therapy should be reserved for the more serious cases of acute myocardial infarction, in which the frequency of thromboembolism justifies the risk entailed in its use.

Thyroid Crisis After Radioactive Iodine Therapy.—Surgical and diagnostic procedures, digitalis intoxication, infections, and psychic shock have been considered capable of precipitating thyroid crisis in patients with thyrotoxicosis. More recently it has been observed that treatment of severe thyrotoxicosis with radioactive iodine may be followed by thyroid crisis. The authors present the case of a man who had thyrotoxicosis with decompensated thyrotoxic heart disease. The patient was treated with maintenance doses of digitalis, bed rest, and phenobarbital. He was given subcutaneous injections of meralluride (mercuhydrin®) solution, which resulted in excellent diuresis. Later he was given a therapeutic dose of 5 mc. of I^{131}. Being restless and impatient, he refused to remain in the hospital. Seven days after I^{131} therapy, he appeared nervous, sweaty, and moderately tachypneic, and had pitting ankle edema. The heart rate was 150 and irregular. He was given 10 drops of strong iodine solution (Lugol's solution) three times daily and 1 cc. of meralluride injection subcutaneously. He was instructed to stay in bed and return to the clinic in one week. The following day he was violently ill with vomiting and diarrhea. Approximately 30 hours later he was brought to the hospital in an irrational state, and died two hours later. The high grade of thyrotoxicosis and the velocity of its development with thyrocardiac complications might have led to thyroid crisis under any therapeutic regimen; however, its occurrence following radioactive iodine therapy suggests that this therapy acted as a factor. The authors recommend daily observation during the critical two week period following I^{131} therapy, when a dangerous exacerbation of toxicity might occur. In selected patients with marked toxicity and limited cardiac reserve, preliminary control with propylthiouracil may be indicated before radioactive therapy is given.

Cervical Smears in Detection of Carcinoma of Uterine Cervix.—Cervical smears are an important means of detecting carcinoma of the cervix, which ranks second to carcinoma of the breast as a cause of death from malignant diseases in women. More than 10,000 smears have been obtained almost routinely in the obstetrics and gynecology section of the Mayo clinic since August, 1950. Records were reviewed of 92 of these patients who proved to have carcinoma of the cervix, although at the time of examination lesions suggesting its presence were not seen. Of these patients, 73 had cervical carcinoma in situ, and their average age was 42.1 years; 11 patients had early invasive carcinoma, and their average age was 47.8 years. Of them 81 were married, 4 widowed, 6 divorced, and one single; 12 had never been pregnant, 4 had had pregnancies resulting in abortion, and 76 had had at least one full-term pregnancy. Only 17 sought medical aid because of gynecologic problems, and in 11 only was malignant growth suspected, whereas in 17 the cervix seemed to be normal. Leukoplakia, believed to be a precancerous lesion, was found in eight patients only. The appearance of the cervix justified biopsy in 49, whereas only a smear was taken in 38 at the time of the first examination. When the patient has an obvious carcinoma or positive and equivocal smears biopsy should be done before treatment is undertaken. Many times, however, a single smear was more efficacious than random biopsy. In detection of carcinoma of the uterine fundus smears were not helpful. It appeared that patients whose smears are positive for carcinoma of the cervix do not have characteristic symptoms or physical signs, and carcinoma in situ and invasive carcinoma of the cervix may be asymptomatic and/or clinically undetectable. Annual or biannual smear screening of apparently normal women is a good preventive measure.

Lipid Metabolism in Atherosclerosis.—Results of recent studies reported in the literature indicate that the various lipid and lipoprotein components of serum are transported normally in a physicochemical state of equilibrium that maintains lipid material in a finely dispersed stable "emulsion." It is believed that any deviation in normal lipid metabolism great enough to unbalance this mechanism results in the aggregation of abnormal colloidal lipid-bearing particles, which are susceptible to deposition in the arterial intima. At least three indications of such a metabolic defect have been related recently to the etiology of atherosclerosis: (1) elevation of the serum cholesterol-phospholipid ratio, (2) sustained chylomicronemia (the presence in human serum of relatively large and numerous fat particles determined by the dark field microscope), and (3) certain abnormal serum lipoproteins in the form of giant molecules. The etiology of the faulty mechanism that produces these changes is obscure at present. However, some hormonal deficiency or imbalance is suggested by the close association of degenerative vascular disease with certain alterations of endocrine function, and by increasing evidence that lipid metabolism is influenced by the action of various hormones. Thus it is possible that atherosclerosis may be shown ultimately to be a metabolic disease initiated by abnormalities in lipid metabolism that result from endocrine dysfunctions. Under these conditions, an excessive fat intake by a person with a preexisting metabolic deficiency might be important in determining his susceptibility to atherosclerosis. In this connection it has been demonstrated that certain atherosclerotic patients benefit from dietary restriction of fats. This concept of the role of metabolism does not exclude other factors in the pathogenesis of atherosclerosis.

Angiocardiography in Complete Transposition of the Great Vessels.—The angiocardiographic findings in 13 patients with proved complete transposition of the great vessels are described. They are classified according to the presence of associated anomalies, such as interatrial or interventricular septal defects, a patent ductus arteriosus, or a combination of these defects. The procedure is evaluated according to its ability to establish a diagnosis of transposition of the great vessels and to reveal the presence and size of the concomitant anomalies. It was found that the angiocardiographic findings were sufficient to make the diagnosis of complete transposition of the great vessels in 10 of the 13 cases. The diagnosis had been suspected, however, from routine clinical and roentgenographic findings. In three cases in which the diagnosis was not suspected, angiocardiography did not establish the diagnosis. In each instance bizarre features made the diagnosis more difficult. The presence and size of a significant associated interatrial defect can be determined with a fair degree of reliability by angiocardiography. If the defect is so large that further enlargement by surgery is not indicated, the authors believe that it will always be demonstrated by a technically satisfactory angiocardiogram. Concomitant interventricular defects rarely were directly demonstrated. Occasionally their presence could be inferred from associated findings. Angiocardiography did not demonstrate a patent ductus arteriosus in four cases in which the ductus proved to be over 3 mm. in diameter. No deaths resulted from angiocardiography either in the 13 cases or in an additional group of 38 patients in whom a transposition of the great vessels was thought to be present. Even though most of the patients were severely incapacitated, they tolerated the procedure well, with only a transient period of discomfort. There was an immediate high concentration of the contrast substance in the aorta and presumably in the coronary arteries. The difficulties in differentiating complete transposition from a complete transposition of the aorta with a levoposition of the pulmonary artery are discussed. Other limitations and shortcomings of the procedure are considered.

Cancerigenicity of Nickel in Rats.—In view of the growing importance of metal cancerigenesis, experimental studies were initiated dealing with the following metals or their compounds: arsenic, chromium, chromite ore, nickel, uranium, beryllium, and asbestos. This paper reports results obtained in 70 rats to which pure metallic nickel powder suspended in lanolin was administered by three different parenteral routes: into the femur, pleural cavity, and nasal cavity. Cancerous reactions were observed in 30% of the animals that died from 7 to 16 months after the start of the experiment. Six of the neoplasms were apparently osteogenic sarcomas, one originated from connective tissue at the site of injection, one from the epithelial lining of an osteomyelitis fistula, and two seemed to have developed from abdominal lymph nodes. The evidence obtained strongly suggests that finely dispersed metallic nickel may elicit cancerous reactions. The minimal latent period was about six months. The importance of these observations lies in the fact that reports from some English nickel ore refineries indicated an excessive frequency of cancer of the lung, nasal cavity and nasal sinuses among workers engaged in operations involving exposure to nickel carbonyl. No similar observations have been recorded from countries where the Mond process of nickel ore refining is employed. While some investigators favored the view that exposure to sulfuric acid fumes containing arsenic generated during the refining process was responsible for these respiratory cancers, this view has been largely abandoned in recent years. Circumstantial evidence incriminates exposure to nickel carbonyl vapors.

Herpes Zoster of Cranial Nerves.—With the exception of herpes zoster ophthalmicus, herpes zoster of other cranial nerves is rarely diagnosed, although it occurs often. The basic lesion of herpes zoster is probably an inflammatory process in the dorsal root or cranial sensory nerve, caused by a neurotrophic and epidermotrophic virus. The cutaneous or mucosal vesicle is thought to result from peripheral migration of the virus from the ganglionic focus to cutaneous and/or mucosal epithelial cells. A virus has been shown to be present in the vesicles. The authors discuss the manifestations of herpes facialis (gasserian ganglion), herpes oticus (geniculate ganglion), herpes auditorius (vestibular and cochlear ganglia), herpes pharyngis (glossopharyngeal ganglia), herpes laryngis (vagal ganglia), and herpes occipitocollaris (cervical ganglia). It is common for herpes of cranial nerves to be manifested by only part of the usual symptoms. For example, in the vagus syndrome there may only be pain and vesicles in the hypopharyngeal region, with no involvement of the ear, motor manifestations, or other possible complications. There are also combinations of involvement of multiple nerves, such as herpes facialis with ocular paralysis or facial paralysis, or geniculate and auditory ganglia involvement, or a vagoglossopharyngeal syndrome. In the event of the development of pain and vesicles in a zoster zone of a sensory nerve, it is important to search carefully for possible motor involvement of the fibers of the same nerve or of a neighboring nerve. An attack of herpes zoster does not confer permanent immunity. The disease is self-limited, lasting three to six weeks. Motor paralysis, if present, may last longer, and in elderly and debilitated patients a troublesome, painful, postherpetic neuritis may persist for months. There is no specific therapeutic agent for herpes zoster. Aureomycin or chloramphenicol in large initial doses (4 gm. daily) should be given in selected cases to combat secondary infections and ophthalmic complications. Local treatment should be directed towards combating secondary infections by the use of medicated powders or ointments. Attempt should be made to control pain with such analgesics as the salicylates, with codein or meperidine (demerol®) in severe cases. Caution is necessary in the use of opiates, particularly in cases with persistent postherpetic neuralgia.

Cor Pulmonale Resulting from Chest Deformities.—Severe and possibly also moderate chest deformities have a harmful effect on the thoracic viscera. Deformities such as kyphoscoliosis, scoliosis, and kyphosis may affect the lungs, causing atelectasis as a result of lack of space, compensatory dilatation and emphysema, and frequent attacks of bronchitis. The heart is frequently displaced upwards to the side opposite the scoliosis, and this displacement is often accompanied by bending and twisting of the aorta and great vessels, especially in cases of right-sided kyphoscoliosis and scoliosis. The changes accompanying right-sided kyphoscoliosis cause compression and concavity of the left chest, which in turn produce a horizontal position of the heart. Hypertension in the pulmonary circulation caused by the pathological pulmonary changes associated with kyphoscoliosis results in hypertrophy and dilatation of the right side of the heart. The author's series, chosen from persons awarded invalidity pensions on account of spinal deformity by the Danish Invalidity Court between 1935 and 1944, included 41 living patients and 62 who had died. Grade 3 deformity was present in most cases. Signs of cor pulmonale were found in 20 of the 41 patients still living. Electrocardiograms were made in all 41 cases; right cardiac strain appeared in 15 and left cardiac strain in 8. Dyspnea is usually the earliest symptom; it may be present for years without interfering with working capacity, but when it is increased by minor exertion, heart failure is impending. The patients with cor pulmonale showed greater debility than the others, and orthopnea with or without cyanosis was found in 15. Study of the death certificates and inquiry from attending physicians showed that 39 of the deceased patients had had signs of cor pulmonale; of these, 37 died in heart failure. Causes of death next in frequency were pneumonia and, according to the certificates, "heart disease" and "myocardial degeneration." The depressant effect of morphine on the respiration is particularly dangerous to patients with spinal deformities who are in pulmonocardiac failure; one patient in this series died following injection of 1 cc. of morphine. Another death followed administration of a local anesthetic.

Results Obtained in Treatment of Acute Appendicitis. R. R. Swinnen.—p. 53.

Use of Küntscher's Intramedullary Pin.—Kütscher's intramedullary pin was used in 541 fractures treated at the surgical clinic of the University of Utrecht and at a hospital in Nijmegen. Most of the patients observed at the latter hospital had war injuries and were treated without penicillin, whereas most of those treated in Utrecht were admitted after the war, when penicillin and other antibiotics were available. About 50% of the total were treated without antibiotics. Küntscher's method consists of introducing a stainless steel pin, U-shaped in cross section, into the medullary cavity through a small incision well away from the site of the fracture. Failure following the use of Küntscher's medullary pin is almost always due to technical errors or imperfections. Good results can be expected only when these imperfections are avoided. The method is superior to others in that it makes possible stable fixation of the fracture and complete functional restoration. The method is indicated in all cases of transverse diaphyseal fracture of the long bones. Other indications depend on the skill and experience of the operating surgeon. Since the "open" and the "closed" method at present offer an equal risk of infection, the "open" method is to be preferred, because it is technically less difficult and safer. Indications for use of this method will increase with further simplification and introduction of various special types of pins. The method should be used only by those who are experienced in its use and have at their disposal all necessary equipment.

Strangulation of Penis.—The most frequent causes of strangulation of the penis are revenge, onanism, and superstition. Strangulation of the penis is followed within the first 24 hours by acute edema, stagnation of urine, and frequently by fulminant gangrene, which can be prevented by prompt removal of the strangulating body. Cases of tolerance for nine months before appearance of gangrene have been reported. The authors report two new cases in a child and an onanistic man 73 years old. The victims were seen 3 and 15 days, respectively, following the strangulation. The case in the old man is unique in the literature. The metallic cylinder introduced weighed 155 gm. It was 8.5 cm. long, with a lumen 2.5 cm. in diameter and walls 0.5 cm. thick. Amputation under general anesthesia was necessary.

*Diagnosis and Treatment of Bronchopneumonia Due to Whooping Cough. Beckers.—p. 377.

Bronchopneumonia Due to Pertussis.—Beckers stresses that in diagnosis of bronchopneumonia due to pertussis two forms should be differentiated: (1) the pneumowhooping cough of Julien-Marie, which is hematologically characterized by the presence of many leukocytes and lymphocytes; (2) bronchopneumonia of the mixed infection type, with an increase in neutrophils but a less decisive increase in leukocytes. The treatment of these two forms differs: in the so-called pneumowhooping cough, the author recommends administration of a specific antibiotic such as terramycin, aureomycin or streptomycin, inasmuch as there may be a difference in sensitivity of some strains against these specific antibiotics. In the treatment of bronchopneumonia due to mixed infection it is essential to administer besides one of these antibiotics also penicillin, which has previously been the drug of choice in treatment of pneumococci and streptococci, chief causes of mixed infections.

Bladder Tumors Following Exposure to Dyes.—The occurrence of bladder tumors in workers in the dyestuffs industry was observed by Rehn in Germany as early as 1895 and by the third decade of this century exposure to beta naphthylamine and to benzidine had been accepted as a cause of bladder tumors by many European observers. American investigators, however, are less certain of the carcinogenicity of benzidine, and stress that it cannot be accepted as such until it is known that benzidine workers without exposure to beta naphthylamine have developed tumors of the bladder. This paper reviews 66 cases of bladder tumors in workers engaged in the manufacture of dyes. Thirty of the 66 patients had been exposed only to benzidine and never to beta naphthylamine, and for this reason benzidine is considered as dangerous a carcinogen as beta naphthylamine. In 15 patients the tumors are attributed to beta naphthylamine alone and in others to mixed exposures. For those entering the industry under 30 years of age the average age of onset of tumor was 42 and of death was 44; of those between 30 and 40 the average age of onset was 51 and of death 54; and in those over 40 the average age of onset was 58 and of death 66. According to the registrar general's figures for 1947 the average age of death of 1,417 males in England and Wales who died of neoplasms of the bladder, urethra, and ureter was 67.5 years. Men under the age of 30 should not be employed in the manufacture or handling of substances known or suspected to be bladder carcinogens and, when possible, healthy men over 40 should be employed on these processes. Methods of prevention are discussed, and it is pointed out that a different method of manufacture for beta naphthylamine has been introduced.

Splenic Puncture.—Splenic aspiration was performed in 43 patients with different diseases of the blood associated with enlargement of the spleen. The cellular pattern of the aspirated material was studied under oil immersion. Evidences of myeloid metaplasia were observed in patients with polycythemia vera and chronic granulocytic leukemia, and in one patient with cirrhosis of the liver. The association of a fibrotic or sclerotic bone marrow with extensive myeloid metaplasia of the spleen is an absolute contraindication to splenectomy, since the spleen in these cases represents the major hematopoietic tissue. The increased number of erythroblasts found in some of the patients with chronic lymphatic leukemia, acquired hemolytic anemia, and cirrhosis of the liver is probably indicative of small ectopic foci of erythropoiesis. Their presence in association with a cellular or hypercellular marrow does not necessarily contraindicate splenectomy, and the recommendation for splenectomy in these cases should be based only on the fundamental disease and on the presence of associated hemolytic anemia. Splenic puncture is useful in the diagnosis of atypical or cryptic types of aleukemic leukemia and leukosarcoma when the marrow picture may not be completely diagnostic or may even be normal. This is particularly true in primary lymphosarcoma and in reticulum cell sarcoma of the spleen in which splenomegaly may be the only abnormal finding. In congestive splenomegaly due to various causes such as cirrhosis of the liver, corroborative evidence in favor of the diagnosis may often be provided.

Corticotropin and Cortisone in Rheumatoid Arthritis.—A course of corticotropin (ACTH), consisting of 12 injections of 25 mg. intramuscularly every six hours, was given to 17 patients with rheumatoid arthritis. After a rest period of at least four days a similar course of cortisone was given, using an oral dose of 50 mg. of aqueous suspension every six hours. The clinical and eosinopenic responses of the patients to these courses were studied. Four patients responded fully to both drugs, four gave no response with either drug, four responded fully to cortisone but only partially or not at all to corticotropin, while one responded fully to corticotropin and only partially to cortisone. The remaining patients gave only partial responses to either or both drugs. The authors' observations suggest that with cortisone and corticotropin great differences in responsiveness may commonly be encountered in patients with rheumatoid arthritis, and the individual patient's responsiveness should be considered before any treatment with these drugs is begun. The single dose test with 50 mg. of cortisone orally and with a single intramuscular injection of 25 mg. of corticotropin may give a useful indication of this, though the three day test would be more reliable. The occurrence of withdrawal deterioration in three patients in whom the drug had had no apparent effect suggests that the differing response of individual patients to administered cortisone and corticotropin may be partly a reflection of the level of endogenous production. If the administered dose of hormone greatly exceeds endogenous production, it causes some degree of hypercorticism, with eosinopenia and suppression of the inflammatory reaction, resulting in a clinical response; but, if the administered dose is less than the amount produced endogenously, the pituitary-adrenocortical system merely adjusts itself to a lower level of production and the net result is no change, though there may be a temporary withdrawal deterioration while endogenous production is being resumed.

*Reduction in Blood Pressure by Hexamethonium Bromide to Prevent Surgical Bleeding. P. Wilflingseder.—p. 619.

Hexamethonium Bromide to Prevent Surgical Bleeding.—Wilflingseder reviews observations on more than 50 operations carried out at the University of Innsbruck with drug-induced blood pressure reduction. Extensive operations on face and neck were greatly facilitated by the use of hexamethonium bromide. Transplantation of large skin flaps is largely dependent on whether the formation of a hematoma can be prevented, and this is possible by means of blood pressure reduction with hexamethonium bromide. Fenestration operations, antrotomy, and operations on the neck are also facilitated by blood pressure reduction. In operations for hernia of the nucleus pulposus blood pressure reduction is helpful, provided the patient can be put in proper position, with head and upper body lowered. Thoracic surgery was likewise facilitated by the use of hexamethonium. In intra-abdominal and proctologic operations the method does not seem indicated, because putting the patient into a position that will drive the blood away from the surgical field is difficult or impossible, but at the Innsbruck clinic the method was tried in urologic operations such as prostatectomy and electroresection, so far with favorable results. From 20 to 50 mg. of hexamethonium bromide is administered intravenously as soon as regular respiration has set in following induction of anesthesia. Then the surgical field is elevated and up to 200 mg. more is given or the surgical field is elevated further until the surgical field is free of blood. If muscular relaxation is desirable for intubation or operation, decamethonium should be given rather than curare, in order to avoid antagonism of the hexamethonium. Generally from three to five minutes are required until pressure has been reduced to 65 to 55 mm. Hg. If this low pressure cannot be reached, even values of 90 to 80 mm. Hg will be helpful. As a rule, surgery should not last more than two hours, but the surgical posture must be maintained for a few hours after operation to avoid postoperative hemorrhage. The method is contraindicated in children, and in patients whose general condition is poor, who are subject to anginal attacks or cerebral thrombosis, or who have chronic pulmonary disorders. The physiology of the method and all possible risks are not yet fully explained.

Renal Infarction and Hypertension.—In 38 patients between the ages of 17 and 63 operated on for various renal disturbances, a true aberrant renal vessel, i. e., an artery supplying the parenchyma of the kidney or a vein of the parenchyma, was either sectioned or ligated. Permanent hypertension developed in 7 (19.4%) of the 38 patients. As a rule pulsating, aberrant vessels should not be sectioned and the intervention should be limited to nephropexy, ureterolysis, or transplantation of the ureter. Despite favorable results of a clamping test, ischemia of a large area of the kidney may result from sectioning of an aberrant vessel. Excision of the ischemic area should then be performed to prevent hypertension. In cases of considerable permanent hypertension, nephrectomy is the method of choice. Experience showed that the younger the patients and the shorter the duration of the hypertension the better the chances for the pressure to be restored to normal. Nephrectomy must be performed before irreversible changes in the vessels of the other kidney occur that will maintain the hypertension. In one of the authors' patients, as early as within three months of the onset of the hypertension arteriosclerotic changes were microscopically demonstrated in the portions of the kidney not involved in the infarction. In cases in which hypertension has continued for some time, it seems advisable to combine nephrectomy with lumbotransdiaphragmatic sympathectomy. Since malignant hypertension may result from partial renal infarction, blood pressure measurements should be taken for prolonged periods in cases in which ligature of aberrant renal vessels could not be avoided. The authors believe that the occurrence of hypertension depends on a hereditary predisposition to hypertension, with an abnormal vascular reaction.

New Concept of Myocardosis.—In evaluating cardiac disturbances in his patients the physician may be aided by a new concept of myocardosis suggested by Wuhrmann. According to this Swiss worker, myocardosis may be considered a syndrome in patients with cardiac disturbances associated with changes of the blood proteins (dysproteinemia). The latter changes may very likely be the cause of the cardiac disturbances. This new concept will be useful in all cases in which the dysproteinemia can be easily demonstrated by combined simple methods, such as determination of total protein content of the blood, Takata test, cadmium sulfate test, Weltmann's serum test, thymol turbidity test, and blood sedimentation rate, and in which no other cause of the cardiac disturbances can be found. Myocardosis may frequently be associated with disease due to malnutrition, but is usually masked by dystonia.

*Possibilities and Limits of Methods of Removing Obstruction of Common Bile Duct by Administering Chemicals or Pharmacodynamic Substances. J. Sénèque, M. Roux and C. Chatelin.—p. 340.

Use of Chemical and Pharmacodynamic Substances in Obstruction of Common Bile Duct.—Pribram's method of treatment for residual calculi combined with intravenous administration of pharmacodynamic substances following cholecystectomy, cholecystostomy, or choledochotomy was used by the authors in nine patients. Two or three times a day, 3 or 4 cc. of a mixture of 8 parts of ether and 2 parts of alcohol were instilled through an indwelling tube in the common bile duct. This was followed by instillation of 5 to 10 cc. of tepid olive oil. In the morning and in the evening the patients in addition were given slow intravenous injections of aminophylline or of sodium dehydrocholate. Excellent results were obtained in eight of the nine patients, while one patient was a therapeutic failure. These results suggest that postoperative medical treatment of obstruction of the common bile duct is indicated if the presence of small calculi has not been recognized during surgical intervention performed under radiomanometric control. In all cases with moderate dilatation of the biliary passages and slightly increased pressure values, the calculi may be removed as a rule by instillations of olive oil alone, or only by injections of aminophylline, sodium dehydrocholate, or even atropine. Such treatment may be likewise effective in cases in which, because of the general condition of the patient, a simple cholecystostomy was done and calculi deliberately were not removed. Besides, if small calculi have been detected closely adhering to the wall of the common bile duct because of concrete biliary sediment, simple drainage of the common bile duct may be deliberately carried out in the presence of insignificant distention of the bile duct and pressure values below 20, and secondary treatment according to Pribram's technique then may be considered. The only disadvantage of this type of treatment consists in the long duration that occasionally may be required, but it is not associated with any risk. The duration of the treatment can be shortened if the calculi are free and the papilla patent. It is emphasized that the treatment should be given outside of the digestive periods, and aspiration of several cubic centimeters of bile from the bile ducts should always precede instillation of the drugs.

Is the Eosinophil Test Specific? A. Hitzelberger, W. Ruppel and L. Weissbecker.—p. 470.

Liver Changes Resulting from Treatment with Thiosemicarbazone.—The damaging effects of the thiosemicarbazones on the liver were studied with the aid of 124 puncture biopsies carried out on 86 patients who were receiving these drugs in the treatment of tuberculosis. In a number of patients, the liver, which had already been impaired by the tuberculous toxin, sustained added damage, which became evident particularly in increased peripheral fatty lobular degeneration and in an increase in periportal round cell infiltrations, in those who were treated with "tebethion" (*p*-acetylaminobenzaldehyde-thiosemicarbazone). Comparisons between certain functional tests of the liver and the puncture biopsies indicate that the functional tests are not sensitive enough to detect mild parenchymal liver lesions. Only a third of the functional tests indicated any pathological structural changes in the tuberculous patients. Fatty degeneration and focal lesions such as tubercles were not revealed by the chemical functional tests. Impaired feeling of well-being on the part of the patient, loss of appetite, and gastrointestinal disturbances are better indicators of the severity of the hepatic lesions than the functional tests, because, with increasing severity of liver damage, the intolerance for the chemotherapeutic substances increases.

Action of Corticotropin on Blood and Bone Marrow.—Blood and bone marrow changes were studied in 12 healthy men after a single injection of 50 mg. of corticotropin and in a woman who had received a total of 1,200 mg. of corticotropin for chronic polyarthritis. It was found that the decided decrease in blood eosinophils was not accompanied by an equal reduction of bone marrow eosinophils. On the contrary, there was an increase, which during prolonged corticotropin therapy became considerable and involved chiefly immature forms. In a patient who had high blood and bone marrow eosinophilia because of Löffler's eosinophilic pulmonary infiltrate, administration of 125 mg. in 24 hours did not cause a reduction in the immature eosinophils. The sharp decrease of eosinophils in the blood under the influence of glucocorticoids is explained on the basis of one or several of the following factors: destruction of cells in the peripheral blood or in certain organs; temporary retention of the cells in certain circulatory regions (disturbance in distribution); and prevention of maturation or of release of cells in the bone marrow.

*Late Prognostic Findings in 140 Patients Following Acute Myocardial Infarction. P. Trivella.—p. 586.
*Atypical Forms of Generalized Carcinosis. E. Cacciapuoti.—p. 597.

Prognosis of Myocardial Infarction.—A follow-up was made of 140 patients 3 months to 15 years after an acute attack of myocardial infarction. At the time of the attack 12 patients were less than 40 years old, 47 were between 40 and 49, 42 between 50 and 59, and 39 were more than 60 years old. Of these patients 52% were living in good cardiocirculatory condition after two years, 37.7% after three years, and 18.8% after six years. Angina had appeared in 25 (17.1%), and heart decompensation in 14 (11%). Prognosis of myocardial infarction is favorable in young persons who, as a rule, are healthy at time of the attack, while older persons may have hypertension and angina. In these the infarct is generally asymptomatic, and may be attributed to endocardial factors, whereas in young persons it may occur because of lipid concentration or a tendency to increased blood coagulation. Of these patients 74 had infarction of the anterior wall, 57 of the posterior wall. In two the infarction could not be localized and in seven it did not involve the entire thickness of the ventricle wall. The site of the infarct is not as important as its size. Preexisting hypertension and angina make the prognosis difficult if they are associated with fibrosis and cerebral arteriosclerosis. When the anatomic condition of the heart is the same at the time of the attack, heart decompensation is likely to develop in the patient with hypertension, while in the patient with angina a recurrent infarct is more probable. The shorter the period of time between the two attacks the less the probability of survival. In seven of the nine patients who died the second attack had occurred within one year. Thus a myocardial infarction may be followed by decompensation, angina pectoris, or restoration of good function of the myocardium.

Atypical Generalized Carcinosis.—Two atypical cases of generalized carcinosis are reported. A few days after giving birth to a child, a 41-year-old woman had a temperature elevation and symptoms that suggested puerperal sepsis, which, however, was not confirmed by gynecological examination. Results of serum and blood tests were normal, but roentgen examination revealed small miliary nodules in the lungs of metastatic nature. A latent microscopic neoplasm of the uterus that became active at time of pregnancy was considered. Swelling of the left inguinal lymph nodes occurred, and biopsy revealed epithelial carcinoma. Had the swelling not appeared a correct diagnosis would have been impossible, since autopsy was not permitted. The second patient was a 38-year-old single woman from a family in which five of eight members, including the mother, had died of neoplastic disease. The tumor always appeared when the persons were between 35 and 40 years old. First symptoms in this patient were abdominal effusion, followed later by pleural effusion in the right side, intermittent temperature elevation, sweating, and little involvement of the general condition. Polyserositis of tuberculous nature was considered and at first seemed to be supported by the fact that the pleural effusion receded almost completely, to reappear only toward the end of the disease. Suddenly the symptoms became aggravated, edema of the legs became severe, and abdominal edema regressed only slightly after tapping. The change of fibrinous serum to hemorrhagic serum, the presence of palpable masses in the abdomen, and swelling of the lymph nodes in the axillary region suggested carcinoma. Biopsy of the swollen lymph nodes revealed metastasis. The hypothesis is advanced that the neoplasm was latent and was stimulated by tuberculous disease. In both patients the course was unusual and an early correct diagnosis was not possible.

Osteoid Osteoma. G. Bosman and H. N. Hadders.—p. 865.
*Isolation of Herpes Simplex Virus from Brain of a Patient with Acute Encephalitis. H. A. E. van Tongeren and J. G. Y. de Jong.—p. 871.
Commotio Cerebri. A. Verjaal.—p. 877.

Herpes Simplex Virus in Brain of Patient with Acute Encephalitis.—The four-year-old boy whose history is presented had been ill with headache, vomiting, elevation of temperature, and apathy for four days before he was hospitalized. On the sixth day after onset, the boy lapsed into coma and had convulsions, tremors, a varying degree of spasticity of the legs, and disturbed reflexes. There were also signs of gastrointestinal disturbance. Papilledema with hemorrhages of the fundus oculi were seen shortly before death. No labial herpes or any other form of herpes simplex infection was observed on the skin or mucous membranes. Necropsy corroborated the diagnosis of encephalitis. Virus was isolated from the brain with the aid of mouse passages. Cross immunization tests carried out between the freshly isolated virus strain and an established strain of herpes simplex showed them to be immunologically identical. The etiological connection between herpes simplex virus and meningoencephalitis had been demonstrated by Levaditi and Harvier in 1920 and subsequently by others, but the total number of cases in which such a relationship has been proved is small.

*Cause of Death in Diabetes Mellitus. F. Heintzelmann.—p. 560.
Status Asthmaticus Treated with Ether Anesthesia. O. Storm.—p. 568.
Thrombocytopenia in Diseases of Liver: Case of Cirrhosis of Liver with Severe Thrombocytopenia and Esophageal Varices. G. Thymann. —p. 571.

Cause of Death in Diabetes Mellitus.—Heintzelmann analyzes the causes of 2,260 deaths of diabetics in Denmark in 1947-1949. In most cases death was due to degenerative heart disorders. This cause of death predominates mainly in the age group of 45 to 64, but is an important cause among men in the age group from 15 to 44, in which death is also often caused by renal diseases, which is more common among men than among women, and by tuberculosis, and in a number of cases by the diabetes itself (diabetic coma). The last-named is almost exclusively the cause of death among diabetic children. In diabetics in the age group over 65 death is most frequently due to senile disorders (cardiac disease, cerebral hemorrhage, and senility). The relatively rare occurrence of cancer as the cause of death in diabetics is stressed. Tuberculosis is the cause of death in diabetics somewhat oftener than in the total population, heart disease and arteriosclerosis are the cause much oftener, and death from renal disease is relatively frequent among diabetics. Among the oldest diabetics death from pyelonephritis is more frequent in men than in women.

BOOK REVIEWS

Cellular Changes with Age. By Warren Andrew, Ph.D., M.D., Professor of Anatomy and Chairman of Department, George Washington University School of Medicine, Washington, D. C. Publication number 127, American Lecture Series, monograph in American Lectures in Anatomy, edited by Otto F. Kampmeier, M.D., Ph.D., Professor of Anatomy and Head of Department, University of Illinois College of Medicine, Chicago. Cloth. $2.50. Pp. 74, with 25 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1952.

This is a brief but comprehensive statement of the anatomic aging changes in living cells. It discusses what is meant by aging of cells in general and specifically in cells of plants, protozoa, and other invertebrates, arthropods, lower vertebrates, and man. It discusses in detail nervous, muscular, skeletal, glandular, fibrous, connective, and surface epithelial tissues and blood in man. Everyone interested in these tissues in health or disease will get valuable and stimulating information. The author suggests answers to some current clinical problems and raises still more questions.

With a broad medical background, Dr. Andrew presents facts primarily as an anatomist and a zoologist. He makes his point that what happens to the cell happens to the man. Studies of aging cells reveal the nature of aging in the man. He points out the great diversity in cells and cell aging processes in man. Some age quickly, breed their kind, and die (blood cells). Some serve best after ceasing to be cells (epithelium); some cells never divide or multiply and never are replaced. Some cells in lower animals live a few hours; in plants, hundreds or thousands of years. The several common varieties of anatomic changes in aging are described, including the variations in mitotic and nuclear changes, accumulations of inert matter, vacuolizations, desiccation, atrophy, degeneration, rejuvenation, and generation. He discusses chemical changes in various parts of the cell and intercellular substances. The works of the leaders in cytology and aging, Lansing, Kountz, Korenchevsky, and Calkins, are cited, and the author's own extensive researches in this field are presented. He notes the significant differences of chronological, physiological, and pathological aging in cells. He stresses the fact that the reason persons and their organs age at different rates and in different ways is due to the aging process in the cells. The book is of much value to medical science and service.

Trompa de Falopio, esterilidad de causa tubaria y asuntos conexos. Por Eduardo Bunster M., médico-jefe de la sección ginecologica del Hospital "El Salvador," Santiago de Chile. Tesis para optar al título de Profesor extraordinario de ginecología en la Universidad de Chile. Cloth. Pp. 549, with 315 illustrations. Guillermo Kraft Limitada, Reconquista 319-27, Buenos Aires, 1951.

This book is intended for physicians interested in gynecology and particularly in sterility. The author, in a compact volume, makes a complete study of the fallopian vestibule and tubes, discussing history, anatomy, histology, and physiology. The physiological aspect is extensively treated, and the author substantiates the opinion that the so-called physiological impermeability of the tubes during the premenstrual stage is erroneous.

There is an orderly study of the different procedures that are used to demonstrate the permeability of the tubes, including hydrointubation, which is seldom mentioned in the English literature. The author modifies the original procedure by the addition of antibiotics which, in his opinion, will make the procedure safer and, at the same time, in some instances assist in treating tubal obstruction.

The surgical treatment of sterility is extensively discussed, and the different procedures are analyzed, taking into account their advantages and disadvantages.

The book is written in Spanish; the subjects are discussed concisely but effectively. This volume, divided into 14 chapters, contains an extensive bibliography.

Surgical Forum: Proceedings of the Forum Sessions, Thirty-Seventh Clinical Congress of the American College of Surgeons, San Francisco, California, November, 1951. Surgical Forum Committee: Owen H. Wangensteen, M.D., et al. Cloth. $10. Pp. 667, with 290 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1952.

The forum on fundamental surgical problems was established in 1941, as a permanent feature of the Clinical Congresses of the American College of Surgeons. It was created expressly to give an opportunity to the younger men engaged in research on surgical problems to present their work before the older members of the profession. The publication of this type of literature has two advantages. It gives the younger men an opportunity to present their research, and it stimulates the older men preoccupied with practical clinical work. The 1952 volume covers most of the physiological problems in connection with modern operative procedures. These reflect definitely a shift from purely mechanical aspects of surgery to the more intricate chemical and physiological problems involved. This attractively published volume deals with many problems in the field of surgery. These brief and important papers should be of great interest to the researchers in the surgical field as well as to the older surgeons engaged in clinical work.

Il cancro. Di Mario Musella. Biblioteca moderna Mondadori CCLXIV. Boards. 250 lire. Pp. 156. Off. graf. veronesi dell'editore Arnoldo Mondadori, Verona, 1951.

This book, written by a well-informed layman, is to be read by educated laymen. Mr. Musella is well known in Italy as a "scientific reporter" and has published other scientific monographs for the general public. In this small volume, the author tries to explain simply but accurately what the modern trends are in cancer research, diagnosis, and treatment. In his rapid review, he touches such varied fields as the interpretation of statistics on cancer morbidity and mortality, the importance of constitutional or inherited predisposing factors, the influence of environment, the role played by the different hormones and by enzyme systems, nutritional factors, and the most recent views on the use of enzyme antagonists. He discusses many of the important "early signs" and gives proper emphasis to the enormous importance of early diagnosis, diagnosis at a time at which cancer is still a local disease. Cancers of the different systems and organs are discussed separately in a manner that should be easy to understand for the average educated person. In other chapters, for example, those dealing with hormones, chemotherapy, and chemistry of nutrition, the discussion is probably above the level of the general public. There are some unavoidable controversial statements, but, as a whole, this volume is well worth reading for one who understands the Italian language. The preface to the book is written by Prof. Hans R. Schinz, director of the radium therapy department of the University of Zurich, Switzerland.

Neurosurgery: An Historical Sketch. By Gilbert Horrax, M.D., Sc.D., Chief of Neurosurgical Service, The Lahey Clinic. Publication number 117, American Lecture Series, monograph in American Lectures in Surgery. Edited by Michael E. De Bakey, M.D., Professor of Surgery and Chairman of Department of Surgery, Baylor University College of Medicine, Houston, Texas, and R. Glen Spurling, M.D. Clinical Professor of Surgery, University of Louisville, Louisville, Kentucky. Neurosurgical Division, editor: Barnes Woodhall, M.D., Professor of Neurosurgery, Duke University, Durham, North Carolina. Cloth. $3.75. Pp. 135, with 41 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, 1952.

This is a brief and enjoyable summary of the development of neurological surgery. It has been written by one of the most able of America's neurological surgeons. Dr. Horrax has been an active participant for more than half of the 66 years that constitute the modern period of this specialty. He has written, therefore, with a background of personal knowledge of his subject and of personal acquaintanceship with practically every man

---

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

who has been responsible for its modern development. In addition to the modern period, Dr. Horrax has dealt briefly with the earlier periods, including the prehistoric era. He stresses the development of neurological surgery on the firm foundations of a thorough knowledge of the nervous system and its diseases and a mastery of sound surgical principles and operative technique. Dr. Horrax has written with the affection of one who has enthusiastically devoted his entire life to his subject.

Manual de radiología clínica. Por el Dr. Juan José Quezada R., profesor de radiología clínica y de fisioterapía en la Escuela nacional de medicina. Cloth. $8. Pp. 254, with 230 illustrations. Impreso por la editorial E.C.L.A.L., Constitución 18, Tacubaya, *México, D.F., 1951.*

This manual partially fills a need for books of this type, particularly in the field of radiology. The majority of the reference books in this field are written in English, German, or French. This résumé on radiology is concise but practical and helpful to the busy practitioner who wants a quick glance at radiological technique or diagnosis. It should also prove helpful to the intern studying radiology and the technician.

Almost every one of the radiological techniques discussed is preceded by a small anatomic description of the part of the body involved. There are numerous graphs and reproductions of radiographs; this makes the understanding of the manual easier and more interesting. The quality of the reproductions is unusually good. There is a bibliography, and an alphabetical index.

The Management of Bronchial Asthma: A Guide to Treatment. By Herbert G. J. Herxheimer, M.D., L.R.C.P.Ed., L.R.C.S.Ed., Research Assistant, University College Hospital Medical School, London. Cloth. $3.45. Pp. 107, with 16 illustrations. Butterworth & Co., Ltd., 4-6 Bell Yard, Temple Bar, London, W.C.2, 1952.

The author attempts, with much success, to guide the inexperienced through the confusion caused by the many methods used in the treatment of bronchial asthma. He points out why one drug will help in certain cases and fail in others and gives detailed information regarding the use of epinephrine, ephedrine, aminophylline, and iodides. He thinks highly of inhalations of isopropylarterenol (isuprel®) hydrochloride, but the average American physician probably prefers inhalations of 1:100 epinephrine. Much space is given to vital capacity tests but none to those breathing tests based on forced breathing over a period of 20 to 30 seconds (the so-called voluntary ventilation capacity). The drugs to be used are tested by vital capacities before and after use. In some cases, the offending allergen is inhaled and any resultant asthma is relieved by inhalation of isopropylarterenol or epinephrine. These inhalation tests are dangerous, as severe attacks of asthma can result.

His discussion on the treatment of psychosomatic factors in asthma is good, especially his statement that "One of the main tasks of the physician must be to strengthen the confidence of the patient," and his note that the patient "should be told that there are good prospects of his improvement, but that it will take time for the correct method of treatment and the individual dosage to be found. This cautious prognosis is usually received well; it prevents disappointment if progress is slow at the beginning."

This volume is small; hence, much is omitted. There is nothing on preventive treatment, which is especially important for children, and no mention of therapy in a hospital. Discussion of the technique of hyposensitization is largely omitted, and the author seems to have little confidence in it; this is in opposition to the experience of most American allergists, for whom the best results in treating bronchial asthma come from carefully observing details regarding avoidance of allergens and hyposensitization against those that act by inhalation. Skin tests are apparently not too useful to the author, and, on page 91, he advises against skin tests "if the history shows definite evidence of polyvalent allergy of the bronchi"; however, it may be questioned why the skin tests, which may give valuable information and which offer no danger if carried out with due precautions, should not be done. Another statement seems wrong: "An examination of the blood for eosinophils is usually not necessary." A minor criticism might be his recommendation of high dosages of drugs, e. g., ephedrine. Despite these objections, there is much in the book that is valuable, especially his ideas on the cause of asthma and his drug therapy.

The Hair and Scalp: A Clinical Study (with a Chapter on Hirsuties). By Agnes Savill, M. A., M.D., F.R.C.P.I., *Consulting Physician to Fitzroy* Square Skin Hospital, London. Fourth edition. Cloth. $5.50. Pp. 316, with 60 illustrations. William Wood & Company (division of Williams & Wilkins Company), Mount Royal and Guilford Aves., Baltimore 2; [printed in Great Britain by Butler & Tanner, Ltd., Frome and London], 1952.

Some of the material in this edition has been reviewed and rewritten, and a few additions have been made. These additions include material on the influence of vitamins and endocrine glands on the condition of the hair and a section on the cold permanent wave. The book is written in an informal, readable style and is by no means a didactic reference work. Unfortunately, a considerable portion of the text consists of comments and case reports based on limited scientific facts, such as a four page discussion of the somewhat antiquated practice of singeing. The volume is completely indexed, and a limited number of references to the recent literature are cited. The book provides a readily accessible source of information of value to the student and to the general practitioner. It cannot be considered as a postgraduate course for the expert.

The Pathology of Diabetes Mellitus. By Shields Warren, M.D., Sc.D., Director of Division of Biology and Medicine, U. S. Atomic Energy Commission, Boston, and Philip M. LeCompte, M.D. Third edition. Cloth. $7.50. Pp. 336, with 115 illustrations. Lea & Febiger, 600 S. Washington *Sq., Philadelphia 6, 1952.*

This edition contains new and revised material on experimental diabetes, diabetes and cancer, diabetes as it affects the kidneys, and on the etiology and pathogenesis of diabetes. A noteworthy addition is the detailed study of 50 autopsies on infants of diabetic mothers. This volume is almost 100 pages longer than the previous edition and contains a good deal of new illustrative material.

The authors have aimed at a complete study of the pathology of diabetes mellitus, based on the analysis of data from more than 800 autopsies of definitely diagnosed cases. Among the subjects covered are diabetes mellitus and the pancreas, pathological evidences of abnormal fat metabolism, the pathology of acidosis and coma, vascular disease in diabetes, the pathology of diabetes in children, pathology of insulin-resistant cases, hyperinsulinism and the pathological effects of insulin, infants of diabetic mothers, cancer and diabetes, experimental diabetes, and medicolegal aspects of diabetes.

There can be no doubt as to the competency of the authors and the adequacy of their treatment of the pathological aspects of the subject. Their pathophysiological considerations are somewhat less adequate, partly because the intricacies of the latter field are undoubtedly less familiar to the authors, trained in another discipline, and partly because they have relied heavily on advice from the Joslin school of diabetes, which does not always correspond with other, equally authoritative views on the subject. With these reservations, however, the pathophysiologic sections serve their purpose in attempting to relate altered structure to abnormal function, and they outline and give references to the important observations that warrant further reading of the original sources. This volume can hardly be recommended as essential for the library of every general practitioner, but it is an excellent reference book and should be owned by every physician who claims a special interest in or knowledge of diabetes.

A Symposium on Essential Hypertension: An Epidemiologic Approach to the Elucidation of its Natural History in Man. Commonwealth of Massachusetts [Recess Commission on Hypertension]. Cloth. $3.95. Pp. 373, with illustrations. Wright & Potter Printing Company, Legislative Printers, 32 Derne St., Boston, 1951.

This book contains reports and discussions that took place at a symposium held Feb. 1 through 3, 1951. It makes available to the student and the clinician interested in hypertension a good summary of the knowledge of the 24 authorities who wrote chapters and of others who participated. Although the epidemiological approach is emphasized, the authors have also covered the problems of etiology, diagnosis, classification, and treatment. The informal questions and answers aid interpretation. The symposium is well worth reading by those interested in this field of study.

STREPTOMYCIN AND DEAFNESS

To the Editor:—*A patient, aged 60, suddenly lost his hearing, while under treatment with streptomycin. What treatment do you suggest to restore his hearing?* *M.D., Michigan.*

Answer.—Neurotoxic effects occurring after the administration of streptomycin or dihydrostreptomycin are not uncommon. Individual sensitivity to both drugs varies greatly. In general, dihydrostreptomycin has a more profound effect on the auditory mechanism than does streptomycin. Streptomycin damages the vestibular apparatus early, while hearing is affected late; in contrast, dihydrostreptomycin causes severe deafness early, while the vestibular function is affected late. In many instances the hearing loss is progressive even after the discontinuance of medication. The prognosis is guarded and distinctly unfavorable in patients having a pronounced hearing loss. There is currently no treatment for this condition.

ELECTRIC SHOCK AND TUBERCULOSIS

To the Editor:—*A man while on a pole came in contact with a 6,600 volt line wire with his left forearm when his right thigh was in contact with the ground wire. He was able to climb down the pole to the ground. He received electrical burns of the left forearm and right thigh. He strained his back in breaking contact with the wire. A routine roentgenogram of the dorsal vertebral column taken the day after injury showed evidence of some lesion in the right upper lung lobe, and roentgenograms of the lung indicated that this lesion was a fibrotic type of tuberculosis. One month later the sputum was found positive for tubercle bacilli. There is a history of blood spitting two and one-half months before injury and of an attack of pneumonia two and one-half years previously. Could the injury described be responsible for activating the tuberculous process present in the lungs?*

Albert H. Winters, M.D., Pittsburgh.

Answer.—High voltage current is destructive of pulmonary tissue in proportion to the amount of current passing through the cells. The higher the voltage, the greater is the destruction. In this case the voltage was high, and no doubt the amperage also was great. It is problematic, however, whether much current went through the lungs at all since a slight contact against the heart would completely disorganize the cardiac rhythm and result in death. Currents of that nature usually zig-zag their way from point of entry through the tissues to the point of exit. The terrific shock and toxicity resulting, however, would in itself be enough to cause an exacerbation of a tuberculous lesion. It seems probable that the patient had latent tuberculosis at the time of the shock, but the shock contributed to or was the direct cause of the exacerbation.

CUSHING'S SYNDROME

To the Editor:—*In* The Journal (148:1166 [March 29] 1952) *an answer is given to a query regarding the treatment of Cushing's disease, which I think is acceptable and logical. With the experience that we have had, however, and the presence of mental disturbance in this patient, I would strongly urge a more radical approach as soon as possible, particularly in view of the fact that the excretion of 17-ketosteroids has attained a level of 29 mg. per 24 hours. In our clinic with proper preparation, I should advise that bilateral adrenal exploration be carried out and, if no tumor is found, one adrenal removed and a very appreciable portion of the second, also.*

The hormone therapy before and after adrenalectomy is of paramount importance. The need for urgency rests on the mental disturbance, which can become permanent if the Cushing's syndrome is not relieved completely in the immediate future. X-ray treatment, in our experience, helps in a very small percentage of cases, and the response, of course, is slow. Without mental symptoms, it is certainly justifiable to proceed serially with the less radical procedures.

George W. Thorn
Peter Bent Brigham Hospital
Boston.

URETHRAL STRICTURE FOLLOWING PROSTATECTOMY

To the Editor:—*I think the strictures Dr. Heins is asking about in the query on urethral stricture following prostatectomy (J. A. M. A., March 29, 1952, page 1167) are the ones that occur mostly in the pendulous urethra. They are probably due to trauma from an electrotome sheath that is inadequately lubricated or to injury to the mucosa produced by tension of the urethra about the sheath, which prevents circulation in the mucosa during the period of the transurethral resection. It is necessary to withdraw the sheath and lubricate it frequently if it tends to be tight in the urethra and does not move back and forth easily. Careful calibration of the urethra should be done before a transurethral resection so as to be sure that there are no places tight enough to fit the electrotome sheath too tightly. If I find a urethra too tight for the no. 28 French sheath, I prefer to use the no. 26 French sheath rather than divulse the constricted area with sounds. The no. 26 French instrument is adequate except for large prostates. These I do not remove transurethrally.*

Montague L. Boyd, M.D.,
563 Capitol Ave., S. W.
Atlanta, Ga.

IODIDES AND TUBERCULOSIS

To the Editor:—*Concerning the query on iodides and tuberculosis* (J. A. M. A. **147**:1091 [Nov. 10] 1951), *considerable damage may result in allowing the answer to stand as published. First, the question of unsuspected tuberculosis of the lung rests in the efficiency of the examining physician, who should, in the light of current education and knowledge, be able not only to suspect but to recognize tuberculous disease if it is present. It would appear to be negligence not to recognize it. Three to four decades ago, before x-ray films were a common or routine procedure in chest examinations, physicians ceased using potassium iodide in 2-grain dosage to increase the sputum and produce a sputum positive for tubercle bacilli. My book, "Clinical Tuberculosis," contains the following statement:*

"Iodine has been used in the form of its alkaline salts, the sodium or potassium, or as the tincture or Lugol's solution which contains these salts in addition to iodine. The use of the alkaline iodine salts in the exudative or caseous pneumonic lesions causes an increase in the blood supply in and about the site of the tuberculous disease. This increases the secretions in this area and tends to break down and carry necrotic tissue from the area of tuberculous disease into the bronchial tract. It thus allows a 'spilling over' of tuberculous infection into uninvolved tissue. It is this action of the iodide salts which for many years, as a diagnostic procedure, was used to produce sputum containing tubercle bacilli, where a questionable tuberculosis existed. This procedure is to be condemned and never employed. Extension of tuberculous disease and hemoptysis have been encountered in many instances following its use. Employing iodine in tuberculosis for a number of years, [I] have used a solution of iodine, in glycerine and alcohol, as below:

Iodine resublimed	*90.0*
Alcohol 95%	*400.0*
Glycerine	*500.0*

Allow to stand for two weeks

This is without the addition of the iodide salts. No deleterious results have been seen from this solution, even in exudative cases where it has been used to treat, or as a diagnostic aid in associated thyrotoxicosis. Iodine is used in pleurisy, especially with effusion, and in some instances of chronic fibroid or the scirrhous type of pulmonary disease, which frequently have associated asthmatic manifestations. The average dose of 10 minims of the above solution may be given in milk three times daily and increased, if necessary, or if symptoms of iodism appear, to as high as 30 to 60 minims three times daily in a glass of milk, preferably after meals."

MEDICAL PROBLEMS CREATED BY A NATIONAL BLOOD PROGRAM

CHAIRMAN'S ADDRESS

Carl V. Moore, M.D., St. Louis

The development of effective transfusion services is one of the major medical accomplishments of the past three decades. During this time, methods have been developed for storing blood; techniques have been greatly improved; additional blood groups of clinical importance have been recognized so that determination of compatibility can be more specific; and plasma has been dried and fractionated. These technical and scientific advances made possible the formation and development of blood banks. Physicians were quick to use the blood as it became more readily available, because mortality was thereby lowered both in civilian and in military practice. This experience stimulated an even more rapid growth of organized transfusion services, both in hospitals and on a community basis. There are now several state-wide transfusion programs, and that of the American Red Cross extends throughout many communities of the nation as a whole. A similar expansion has occurred in many other countries.

The extent and effect of this growth have not been generally appreciated. The second survey on blood banks made by the American Medical Association indicated that, in 1950, hospital blood banks procured more than 1,600,000 pints of blood, Red Cross Regional Centers obtained almost 500,000, and nonhospital blood banks collected nearly 400,000 units.[1] In addition, the survey estimated that roughly 500,000 pints of blood were obtained for immediate transfusion without prior storage. The total is about three million units of blood per year for the United States. Even this high figure, however, needs to be revised upward because of the change since the Korean conflict began. From July, 1951, through April, 1952, the American Red Cross obtained 2,986,600 pints for both civilian and military purposes, while independent banks cooperating in the national blood program obtained an additional 453,000 for military purposes.[2] These figures average slightly more than four million units per year. If it is assumed that hospital and nonhospital blood banks have continued their collections unchanged, then the amount of blood that will be obtained from the American people during the year 1951-1952 will be from six to seven million pints.

This is a record of which medicine, the blood banks, the military establishment, and the persons who give their blood can very rightly be proud. With the phenomenal growth of transfusion services, however, have come two problems: 1. The ready availability of blood has led to its increasing use, without adequate realization of the hazards involved, when no clear indication for transfusion exists. 2. The repeated donation of blood, particularly by women, constitutes a severe drain on iron reserves, so that hypochromic anemia more readily develops. Serious attention should be directed to the desirability of providing iron supplements to women donors in amounts sufficient to replace the iron lost.

UNNECESSARY USE OF BLOOD TRANSFUSIONS

Whenever a blood bank is established in a hospital or in a community, the number of transfusions given often increases several fold. The Red Cross has found that, after a regional center is organized, the amount of blood required by the community is always much greater than had originally been estimated by the physicians and hospitals in that community. The experience in the blood bank that serves the Washington University Group of Hospitals is illustrative (fig. 1). The first full year of operation for this bank was in 1943, when 2,700 transfusions were given; currently almost 8,000 transfusions are given per year. Because the number of hospital beds has increased, and the average stay of patients in the hospital has become shorter, the data in fig. 1 have been charted as transfusions per bed and transfusions per 100 hospital admissions. It is evident that the increase is striking in each instance. The number of transfusions per bed has increased nearly 2.5 times, per admission or per number of patient days nearly two times. Many factors

are unquestionably responsible for this rise. Patients who could have profited from blood *probably* were not given transfusions or did not receive as many, when it was less readily available. The character of surgery has changed to include more thoracic and cardiac operations and a more radical approach to the surgical treatment of abdominal carcinoma. In some instances, however, unnecessary transfusions are being given.[3]

It is almost impossible to determine what percentage of transfusions can be classified as unnecessary. There are numerous instances, however, in almost every hospital in which patients are "prepared" for operation by being given one or two transfusions, even though their nutritional status is satisfactory, their red blood cell levels are above 3,500,000 cells, and their hemoglobin values are above 10.5 gm. Similarly a transfusion is often begun immediately prior to what promises to be an uncomplicated surgical procedure, even though the nutritional and hematological status is good. Women after delivery are occasionally given transfusions before their release from a hospital in order to hasten the return of hemoglobin values to normal, even when only very mild degrees of anemia are present. On medical services, transfusions are also given to patients with only slight decreases of red cells, presumably to speed convalescence or in the vague hope that a sense of fatigue will be relieved. Interns and residents are asked to transfuse blood for its "tonic" effect. There is no need to cite specific cases as examples. Almost every active practitioner can supply illustrations from the hospitals of his own affiliation. Objection to my criticisms may be made because of honest difference of opinion as to the indications for transfusion. Physicians who give blood under these circumstances, however, must be cognizant of the risks involved, and must be prepared to justify the risk.

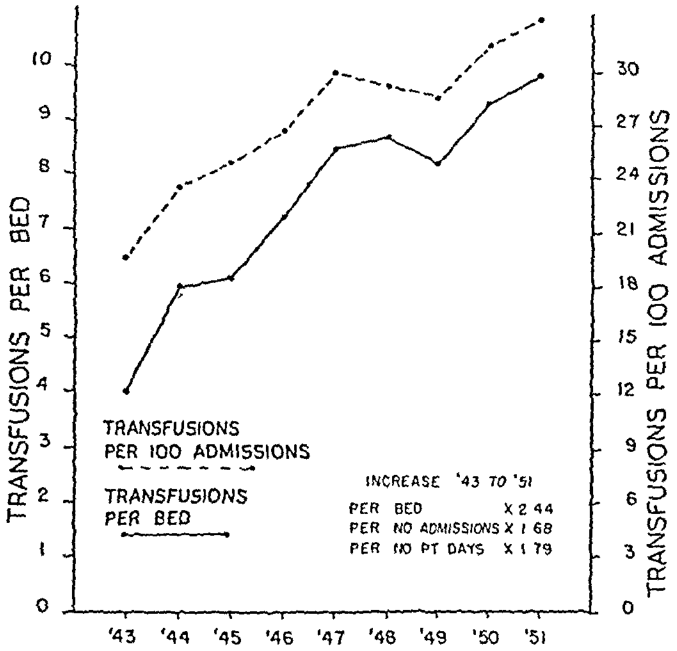

Fig. 1.—Increase in transfusions given in the Washington University Hospitals, including Barnes, St. Louis Maternity, and McMillan Hospitals, after the blood bank was established.

Sufficient emphasis has not been given to the fact that the mortality rate from transfusions probably varies from 1 in 1,000 to about 1 in 3,000.[4] These figures probably represent minimum rates, because they were accumulated in hospitals where one or more physicians have been particularly interested in transfusion services, and have carefully supervised techniques. The reasons for transfusion deaths are many; they include human error, severe hemolytic reactions because the patient has previously been sensitized to one of the rare blood groups, circulatory overload, contamination of the blood, and serum hepatitis. The factor of error is particularly difficult to overcome completely. A blood bank refrigerator, not equipped with a constant recording thermometer, may go off during the night because of power failure. Power is restored, but not until after the blood has become warm. The blood is recooled and the hemolysis that occurs when the red cells are brought to body temperature at the time of transfusion may not be detected unless a sample is centrifuged. Severe hemolytic reactions may therefore result. Not infrequently, patients with very similar names but with different blood types may be in the hospital at the same time; I know of at least one instance when incompatible blood was given because an intern confused the identity of patients under these circumstances. Errors in labeling of bottles or pilot tubes in typing or crossmatching continue to occur. There seems to be an irreducible minimum human error that the most constant vigilance is not able to avoid. Transfusion reactions in the operating room are apt to be particularly severe because the usual early signs are masked by the anesthesia. It is only rarely that one sees a physician or a house officer so aware of the dangers of producing circulatory overload with pulmonary edema that he checks the venous pressure regularly during transfusions to old or severely anemic patients. The reasons for fatal transfusion reactions are too numerous to be discussed in greater detail here; they have been reviewed by numerous authors.[5] The important thing to emphasize is the mortality figure itself. If one accepts the mortality rate of one death in 3,000 transfusions, then for the approximately 3,000,000 transfusions given in this country per year, there must be about 1,000 deaths. The claim has been made that the mortality rate from transfusions approaches that of appendicitis or of ether anesthesia.[3]

Unquestionably, transfusions save many times this number of patients. The risk, when clear indication for transfusion exists, is minimal compared to the risk of not using blood. Some of the deaths, however, certainly occur among patients who do not need transfusions. The best way to avoid such accidents is to discourage the practice of giving blood unnecessarily. A blood transfusion should not be regarded as a tonic.

Of related importance is the fact that the incidence of serum hepatitis from whole blood transfusions is estimated to be from 0.5 to 0.8%.[6] The mortality rate from this cause alone may be as high as 1 for every 6,000 whole blood transfusions.[3] Other factors that make this complication a very serious one are the long illness, the possibility of residual hepatic damage, and the probability of increasing the number of carriers of the serum hepatitis virus.

SUPPLYING IRON SUPPLEMENT TO WOMEN DONORS

The second problem focuses attention on the donor rather than the recipient, and is concerned with the advisability of supplying iron supplements to women donors. The effect of blood donations on iron balance becomes evident from the following considerations. Each 500 cc. of blood with a hemoglobin level of 15 gm. per 100 cc. contains approximately 250 mg. of iron. If this loss is spread evenly throughout one whole year, it is equivalent to an average daily loss of 0.68 mg. of iron. With three donations, the average daily loss would be 2.08 mg., and with five donations, 3.4 mg. (fig. 2). These figures may at first not seem very high, but recent studies on the absorption of food iron have indicated that probably not more than 10%, and certainly less than 20%, of food iron is absorbed.[7] The amount of food iron that would have to be ingested per day in order to compensate for the loss in donated blood, then, even if it is assumed that absorption is 20% complete, would have to be 3.4 mg., 10.2 mg., and 17 mg. for one, three, and five donations, respectively. These requirements, furthermore, must be added to those normally needed to maintain iron balance. There is reason to believe that a dietary intake of 12 mg. of food iron per day maintains the normal woman during her sexually active life in iron equilibrium, but provides only a small margin of safety.[7] Women, therefore, would need 12 mg. of food iron per day plus the additional requirement produced by blood donation.

That many women find it difficult to meet these added demands is indicated, first, by the fact that slightly more than 12% must be refused when they report the first time to give blood because their hemoglobin level is below the minimal standard of 12.3 to 12.5 gm.[8]; and, second, by the fact that the rejection rate because of low hemoglobin values rises with repeated donations. There admittedly are a few women, who, for some unknown reason, are able to give blood regularly and repeatedly without difficulty, but they certainly are the exceptions. The desirability of replacing the iron lost in blood donations by giving iron supplements to women donors was recognized during World War II. Four of the Red Cross centers, those in New York City, Detroit, St. Louis, and Columbus, provided iron supplements to women donors during the last year of the plasma procurement program. The effect of this replacement on the hemoglobin levels of these women has never been analyzed in detail, but there was a definite impression that rejection rates among women giving repeated donations became less. About nine months ago, a similar program was begun at the Red Cross Regional Centers in Columbus and in St. Louis. The medical societies in these two cities approved the plan to supply women donors with iron tablets, since replacement rather than therapy was involved. Iron is never given to a donor until after her hemoglobin level has been found to be acceptable and she has donated blood. It is important to emphasize that, if her hemoglobin value is low, she is referred to her physician for diagnosis and therapy. The donors themselves have accepted the program well, have not been frightened by it, and have reported very few gastrointestinal symptoms from the iron.

NUMBER OF DONATIONS	Fe LOSS AV./DAY	INCREASE IN FOOD Fe REQUIREMENT	
		IF 10% FOOD Fe ABSORBED	IF 20% FOOD Fe ABSORBED
1 PER YEAR	.68 mg.	6.8 mg.	3.4 mg
3 PER YEAR	2.04 mg.	20.4 mg	10.2 mg
5 PER YEAR	3.40 mg.	34 0 mg	17.0 mg.

Fig. 2.—The effect of donation of blood on iron loss and requirement in women. If the hemoglobin level is 15 gm. per 100 cc., 500 cc. of blood contains approximately 250 mg. of iron.

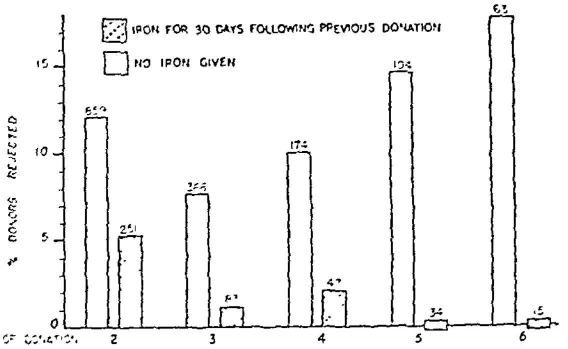

Fig. 3.—Chart showing the effect of iron replacement on rejection rate due to low hemoglobin values in 1,110 women. The number at the top of each column represents the total number of donors on which the observations were made, i. e., of 859 women donors who had not taken iron and who reported for a second donation, 12% were rejected because of low hemoglobin. The dotted columns for donations 5 and 6 are charted as far below as above the base line to indicate that there were no rejections in this small group of women

Each woman donor is given an envelope containing 100 tablets, each of which contains approximately 0.3 gm. of a simple ferrous salt. The following statement is printed on the envelope:

> A normal healthy adult can donate a pint of blood with the assurance that his health will not be injured. This involves, however, the replacement of (1) fluids, (2) proteins, and (3) iron, which is used to regenerate the hemoglobin. The average diet is usually quite adequate to maintain balance in these three relationships. An additional supplement of iron, however, will frequently accelerate the replacement of hemoglobin and red cells.
>
> For those donors who care to act upon this information, inorganic iron in amounts calculated to replace that in donated red cells is available in this sample.
>
> Take one tablet before breakfast the first day, one before each of two meals the second day, and one before each meal daily thereafter.

Note: Keep these tablets in a safe place where small children may not mistake them for candy.

The caution about keeping the tablets out of the reach of small children was added because severe toxic reactions have occurred in children who have taken large amounts of iron.[9] It is difficult to obtain exact information about the effectiveness of the supplements, since only a small percentage of Red Cross donors report regularly for repeat donations. The effect on those who fail to return is unknown. Data analysed by Dr. Claire Ramsey for the St. Louis Regional Red Cross Center indicate that the refusal rate among those who do return is dramatically decreased when iron is taken. This information is charted in fig. 3. Except for the unexplained decrease in the rejection rate of third time donors, the percentage of women whose hemoglobin level was below 12.4 gm. increased steadily as the number of donations increased. When iron supplements were provided, however, this trend was reversed, and the rejection rate was strikingly reduced. The results are preliminary but show exactly what one would expect. By administering iron one prevents the development of iron deficiency anemia and thereby very effectively performs a service of preventive medicine. At the same time a continuing supply of acceptable donors is assured.

SUMMARY

Medicine has every right to be proud of the excellent transfusion services that have been developed in this country and in many areas of the world. From research now in progress there is reason to believe that transfusion programs will continue to grow and to become more effective. The greater use and availability of blood have unquestionably led to very significant decreases in mortality rates, in both military and civilian medicine. With this greater use and availability of blood have come two new problems: 1. Transfusions are given when there is no clear indication for their use. However, the risk of serious, even fatal, transfusion reactions is great enough to contraindicate this practice, and it should be vigorously discouraged. 2. Blood donation is a severe drain on the iron reserves of women donors. Iron supplements should be given in amounts sufficient to replace the loss.

ENZYME DEBRIDEMENT OF INDOLENT INFECTED CUTANEOUS ULCERS

John F. Madden, M.D.
and
Harold G. Ravits, M.D., St. Paul

Within the past few years there have been many reports [1] on the enzymatic débridement of fibrinopurulent exudates in empyema, hemothorax, miscellaneous chronic ulcerative lesions, and local infections, such as osteomyelitis and sinusitis. The present study was undertaken to evaluate the efficacy of the lysing enzymes, trypsin, streptodornase, and streptokinase, in the treatment of various indolent infected cutaneous ulcerations. The majority of the ulcerations treated with these substances were of the varicose stasis type, although decubitus, traumatic, arteriosclerotic, and other types of cutaneous ulcers were included in this series.

Streptokinase and streptodornase ("varidase") are used together, although their physiological action is somewhat different. Purified crystalline trypsin (tryptar®) was sometimes used on a patient who was also given streptokinase-streptodornase or on alternating patients. Tillett and his associates [2] showed that hemolytic streptococci produce a fibrin-lysing substance known as streptokinase that acts as a catalytic agent. The fibrin-lysing system is activated by streptokinase, which causes liquefaction of fibrin. Streptokinase also inhibits the change of fibrinogen to fibrin. This product is abundantly excreted into the culture medium and is readily obtainable from broth cultures of hemolytic streptococci in bacteria-free filtrates. Streptokinase has maximal activity at pH 7.3 to 7.6; at pH 5.0, it is inactivated, and at pH 9.0 or higher it is irreversibly inactivated.

These investigators also demonstrated that the bacteria secrete or excrete a second enzyme, streptodornase. This substance acts on desoxyribose nucleoprotein, which is found in purulent and pleural exudates; streptodornase with fibrin accounts for the coagulum and coarse sediment of such material. Streptodornase (desoxyribonuclease) can catalyze the breakdown of desoxyribonucleoprotein and desoxyribonucleic acid. Miller [3] found that it acts only on the extracellular nucleoprotein or on nuclei in degenerating cells but does not attack the nuclei or nucleoprotein of living cells. The action of streptodornase is one of depolymerization by which the long-chained chemical structure of the nucleoprotein is severed at many points. Coincident with this molecular rupture, the inspissated quality of the purulent material is transformed into a thin solution. Streptokinase and

streptodornase cannot digest mucin, collagen, or fibrous tissue, and the presence of large amounts of such substances will seriously interfere with effective enzymatic débridement of fibrinous and purulent exudates. In many cases a combination of enzymatic and mechanical débridement is of value.

Purified crystalline trypsin is a proteolytic enzyme derived from mammalian pancreas. It digests fibrin clots and dead tissue. The products of trypsin action are peptides and some individual amino acids. Trypsin digests the slimy and viscid coating of desoxyribose nucleoprotein of the purulent exudate and then attacks dead tissue in the lesion. The exudate becomes thin and serous, and fresh viable leukocytes appear that help increase the phagocytosis of bacteria. Bacteria rapidly decrease in number and may disappear completely. Trypsin is not bactericidal, and the disappearance of bacteria seems to be caused by a strengthening of the humoral elements of defense and a clearing of debris. By clearing the wound of debris and slough, trypsin denies a medium to the bacteria. Trypsin activity is optimal within a pH range of 6.8 to 7.5. Roettig[4] and his associates stated that it will lyse only dead tissue and will not attack a living cell. On surface lesions the pH of the surface should be tested, and if it is extremely alkaline or moderately acid, trypsin in a solution of Sorensen's reagent should be used as a wet dressing. At temperatures lower than body temperature trypsin is rapidly inactivated; therefore, external heat should be applied to the wet dressing. When allowed to stand in solution at room temperature, trypsin is said to lose 75% of its activity in three hours, and, therefore, continuous effectiveness should not be expected unless the dressings are changed every three or four hours. The activity of trypsin may be stopped by irrigating the treated area with sodium bicarbonate solution.

Twenty-seven patients with cutaneous ulcers were treated in this series. Sixteen of the group had varicose stasis ulcers, four traumatic ulcers, and four decubitus ulcers. One patient was hypertensive; one had a chemical burn; and one had dry gangrene of the toes. The object of the treatment with the enzymes was to remove the adherent fibrinopurulent exudate from the ulcer surface initially in order to proceed with further healing therapies. After a few trial cases it was felt that it would be best to discontinue the enzymatic treatment as soon as the ulcer surface was clean. Continuation of the medication beyond this stage did not enhance the complete healing of the ulcers.

Both streptokinase-streptodornase and purified crystalline trypsin were used in the forms of wet compresses and powders applied to the ulcers. Streptokinase-streptodornase was used in ointment form on three patients. As is shown in the accompanying table the majority of patients were treated with enzymatic wet compresses. When used as a wet compress, 100,000 units of streptokinase and 25,000 units of streptodornase were dissolved in 20 cc. of isotonic sodium chloride solution. This wet pack was applied directly to the ulcer. Moisture was maintained by applying a large isotonic sodium chloride solution compress over the enzyme-medicated pack, which was changed every 12 hours. In three cases streptokinase-streptodornase was used in a water soluble jelly (lubafax®) adjusted to a pH of 7.5. This ointment was used exclusively in two of the patients and alternately with the wet compresses in the other patient. In four other patients, streptokinase-streptodornase powder was sprinkled on the ulcer. The powder was applied to the ulcer every six hours, and an isotonic sodium chloride solution pack was applied over the powder. The powder and the wet pack forms of treatment seemed to be equally effective, although the powder form of treatment was simpler.

Purified crystalline trypsin was also used by direct application of the dry powder to the surface of the ulcer and also as a wet dressing and by infiltration of purified crystalline trypsin solution made by dissolving 250 mg. in 25 cc. of Sorensen's reagent. Purified crystalline trypsin solution had to be freshly prepared every three hours because of loss of potency. Antibiotic therapy, either locally or systemically, was utilized in several patients to prevent spread of infection. In deep decubitus ulcers in which there was a firmly adherent eschar, the débridement was aided by surgical and mechanical removal.

The stasis and traumatic ulcerations of the legs responded most rapidly and dramatically to enzymatic débridement of the purulent exudate on the surface. The results were obtained in 2 to 14 days, the average time for treatment being 6.5 days. Several ulcerations had resisted treatment with many other medications, including wet compresses and antibiotics, and in these cases the responses were significantly impressive.

The decubitus ulcerations were the slowest to respond, and all required the aid of surgical débridement, but at the end of the treatment period the ulcerations were clean, with healthy red granulations in evidence. One patient (case 24), who had extensive and multiple decubitus ulcers, failed to respond to treatment, but this patient had been chronically ill and severely debilitated. She required supplemental feedings and blood transfusions. In another patient (case 7), who had a long-standing history of recurrent stasis ulcers on the lower legs and feet, a surrounding cellulitis developed following treatment with streptokinase-streptodornase packs. Later, purified crystalline trypsin powder was used but only intermittently as it caused pain. The purulent exudate cleared after 10 days' treatment. The patient (case 26) with arteriosclerotic dry gangrene of the toes showed no change following treatment with streptokinase-streptodornase wet compresses for 10 days and streptokinase-streptodornase in ointment form for 5 days.

In one patient (case 10) with large stasis ulcerations on both lower legs we simultaneously compared the two enzymes. After five days the leg ulcerations treated with purified crystalline trypsin seemed much cleaner than those on the opposite leg, which were treated with streptokinase-streptodornase. The powder form of the two enzymes was used with the application of isotonic sodium chloride solution compresses.

Bacteriological studies made on this group of patients revealed only the usual variety of bacterial flora found on cutaneous lesions. No adverse reactions from treatment were noted other than pain on application of the purified crystalline trypsin powder in a few patients. In one patient, a mild cellulitis developed during treatment with streptokinase-streptodornase (see table on next page).

26	M	68	Dry gangrene	Toes, left foot, 3d, 4th, and 5th; right foot, 5th	"Varidase" packs (10 days) Ointment (5 days)	15	Not done	No change after 3 weeks
27	M	28	Chemical burn	Lower leg, 4 × 4 cm.	Tryptar® packs	10	Not done	Cleaned up and healed, slough separated in 5 days

CONCLUSIONS

In this series of patients treated with the enzymes streptokinase and streptodornase ("varidase") and purified crystalline trypsin (tryptar®) favorable results were obtained in 23 of the 27 cases. Eleven patients treated with purified crystalline trypsin responded favorably and two unfavorably. Thirteen patients treated with streptokinase-streptodornase responded favorably and four patients unfavorably. It must be emphasized that the specific action of the enzymes is directed against the necrotic fibrinopurulent exudate seen on the surface of the ulcerations. By their catalytic and enzymatic properties it is now possible to bring about lysis and digestion of fibrin and desoxyribose nucleoprotein when these enzymes are brought into contact with fibrin, pus, and dead tissue. Thus, not only is the pus and debris eliminated, but the formation of healthy granulation tissue is facilitated. It is felt that streptokinase-streptodornase and purified crystalline trypsin should be considered as an adjunct in the treatment of indolent infected cutaneous ulcers. These applications are a valuable aid in removing debris from necrotic lesions that require further competent surgical and medical management.

VIRAL AND BACILLARY DYSENTERY

A DUAL EPIDEMIC

Hobart A. Reimann, M.D., Beirut, Lebanon

Mild, infectious, gastrointestinal disorders, according to many observers, are more numerous and widespread than any other enteric disease, especially in late summer and autumn. Epidemics of nausea, vomiting, and diarrhea, each of several weeks' duration among medical students, nurses, and hospital personnel were studied in 1943 and 1944.[1] The distribution and clinical behavior of the disease suggested filtrable agents to be the cause,[2] and a similar disease was transmitted to volunteers by inhaled [1b] and ingested [3] filtrates of stools obtained from patients. There appear to be at least two similar etiological entities, one febrile and the other not.[3a] Many subsequent outbreaks were reported, with a probable viral cause in mind.[4]

Several inadequate descriptive terms are given to the disease as can be noted in the appended references. The term viral dysentery was proposed to imply bowel trouble caused by one or more filtrable agents. Adoption of the term would favor an orderly nosologic separation of enteric infections caused by viral, bacterial, fungal, or protozoal agents in keeping with parallel etiological classification of other system diseases.

Viral dysentery is in certain respects like the common cold. It is seasonal, contagious, sporadic, and occurs in epidemics. As a rule, it is mild, brief, afebrile, and bedrest is seldom necessary. It seems to be spread by contact or by air-borne particles, not by food or water, and bacteria are not implicated; however, overt signs and symptoms are usually absent. Most victims do not mention diarrhea willingly, and medical aid is seldom sought. Thus, epidemics may be unnoticed, except in closely observed groups or unless special effort is made to detect them.

In mid-September, 1951, a nurse was admitted to the Jefferson Hospital six hours after the onset of severe headache, anorexia, nausea, fever, colic, and diarrhea. The next day, 4 nurses with similar complaints sought treatment, and, on the third day, 7 more; in a week, there were 27 patients. In contrast to viral dysentery, in which patients are seldom sick enough to need special care, the large number of relatively severe cases occurring over several days, limited to nurses, suggested some other cause and led to investigation of the epidemic.

EPIDEMIOLOGY

Inquiry was made on Sept. 20, in the classroom of 320 medical students who lived and ate in various places. About 20% had or had had mild, brief, diarrheal disease over the same period. All were ambulatory. Several students and nurses reported similar disease in members of their families who lived at a distance. For example, a nurse visited her rural home on Sept. 14. On Sept. 16, she awakened with colic and diarrhea and later vomited. On Sept. 17, she returned to the hospital. She was ill en route and was admitted to the hospital with a temperature of 102 F and rhinorrhea. On Sept. 18, at her home,

---

Dr. Reimann is now Visiting Professor of Medicine, American University.

Dr. John R. Griffith of the Jefferson Medical College and Hospital, Philadelphia, aided in the clinical and epidemiological studies.

her mother became ill with rhinorrhea and complained of aches followed by colic, nausea, and diarrhea for three days. On Sept. 21, her father became similarly ill. In another instance, a student who lived at home had diarrhea, sore throat, and chills for five days. His wife had sore throat the next day followed by three days of abdominalgia, anorexia, and diarrhea. Small epidemics were current in other hospitals in the city and its environs and in the practices of interrogated physicians, especially among children. The diverse, widely-scattered groups involved ruled out a common food or water supply as the source of infection. No obvious epidemics of minor disease of the respiratory tract were present.

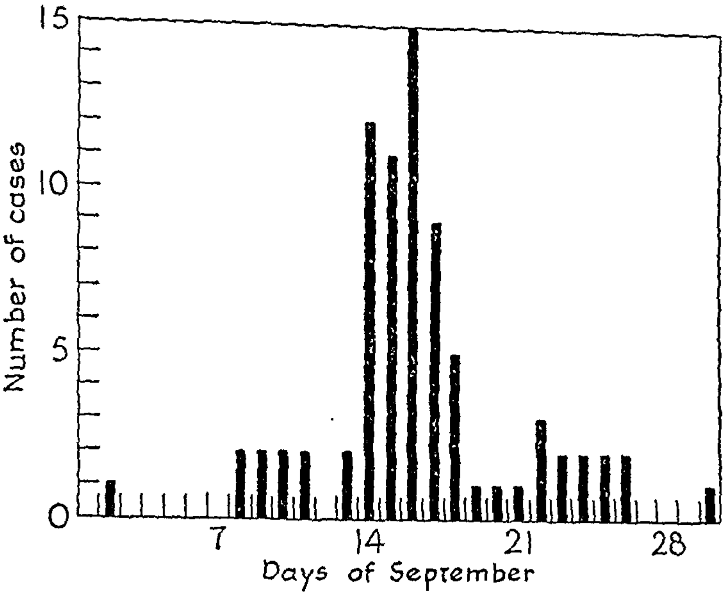

Chart 1.—Days of onset of disease in 78 patients with acute enteritis. All victims were ambulatory except between Sept. 13 and 19, when 27 patients with severer cases were admitted to the hospital; Shigella sonnei was isolated from 12.

On inquiry, it was learned that the first case in the group studied occurred on Sept. 2. Between Sept. 7 and 13, two new ambulatory cases occurred daily, until the admission of 27 nurses to the hospital between Sept. 13 and 19, aroused attention. The date of onset of illness in 79 patients during September is shown in chart 1. Thereafter, between one and three patients with mild cases appeared daily until Sept. 26, and sporadic cases occurred in October. Seventy-five patients were observed, including nurses, students, and other personnel. Many cases, no doubt, were undetected. Except for the "peaking" in the curve of incidence caused by the sudden increment of relatively severe cases, the course of the epidemic resembled the ones referred to previously.[1a]

Of 211 nurses, 54, or 25%, were ill. Half of this group needed care in bed, and they and several other hospital personnel who dined in the same room accounted for the peak of the curve between Sept. 13 and 19. This large proportion of incapacitated patients is not characteristic of viral dysentery, with which only the exceptional victim seeks bedrest. Evidently, the outbreak among nurses was caused by a severe form of viral dysentery, by another enteric infection, or by a combination of the two.

Specimens of stools of 27 nurses confined to bed were cultured routinely in the hospital laboratory, but only colon bacilli, staphylococci, and streptococci were found. On special study, shigellae were isolated from the stools of 12 of 17 patients who took sick between Sept. 14 and 17. After this discovery, it was obvious that the sharply limited outbreak was one of bacillary dysentery. It was unlikely, however, that Shigella colitis accounted for the many mild cases in our group and scattered throughout the city and its suburbs. Cultures of stools, made with an improved technique in the hospital laboratory, of all succeeding patients until Sept. 26, failed to reveal additional cases of Shigella infection. Shigellae were not recovered from stool samples obtained by rectal swabs from 50 nurses who had not been ill or from 146 employees who handled food in the hospital. It seemed, therefore, that a dual epidemic had occurred, composed of widespread viral dysentery with a slowly rising incidence and decline over a month or more and a superimposed sharply defined outbreak of bacillary dysentery lasting about a week and limited to nurses (chart 1).

CULTURAL STUDIES

Stool specimens from 17 patients were cultured by Dr. Kenneth Goodner, who isolated Shigella from 7. Subcultures were sent for identification to the Dysentery Registry in New York City under the direction of Dr. Joseph Felsen and Dr. A. J. Weil. The seven strains acidified a sucrose and lactose medium in a week and were classified as S. sonnei. They grew richly on all mediums, and five decomposed urea in three to five days.

Attempts to transmit viral dysentery experimentally to volunteer students by the inhalation or ingestion of fecal filtrates as described in previous experiments [1b] were not made because of the now known hazard of poliomyelitis, viral hepatitis, or Coxsackie disease. Instead, samples of feces, preserved frozen in carbon dioxide, from the same 17 patients were tested by Dr. Joseph Smadel and Dr. Ross L. Gauld at the Army Medical Center. Intraperitoneal or intracerebral injection of 10% suspensions of the supernatant fluid of centrifugated stools failed to cause significant disease in guinea pigs or in suckling and adult mice. Culture of the stools on McConkey's medium revealed S. sonnei S and R from 11 of the 17 samples. Because of the apparent dual nature of the epidemic, studies were made separately of patients from whom

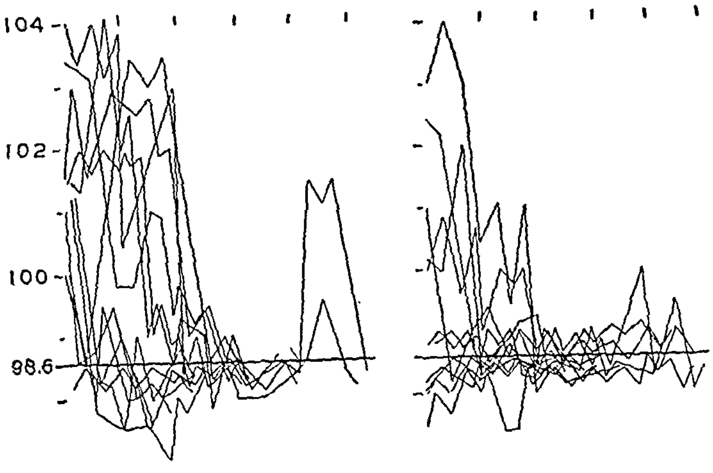

Chart 2.—Superimposed temperature curves of 22 patients ill between Sept. 13 and 19. Left, curves of patients with bacillary dysentery. Right, curves of patients from whose stools Shigella was not isolated.

Shigella was obtained to see whether clinical differences from viral dysentery other than degree of severity could be detected.

BACILLARY DYSENTERY

The disease began between Sept. 14 and 17, in 12 patients from whom S. sonnei was cultured. The initial symptoms were colic, and/or diarrhea in seven, headache in two, nausea in one, vomiting in one, and malaise and a chill in one. During the course of the disease, all patients had diarrhea; colic occurred in 10, nausea in 8, and vomiting in 8. Two had a shaking chill, and six experienced chilliness or chills. A temperature of 100 F or over occurred at the onset or during the course of the disease in 10 patients and lasted two or three days (chart 2). Two had a recurrence. Leukocytosis of 18,000 occurred in only one person. There were from 4 to 20 watery bowel movements a day. Mucus and pus were not observed, but in only one or two patients streaks of blood were present at times. Leukocyte counts roughly estimated in smears of stools stained by Wright's method were between 0 and 70 cells per oil-immersion field. Four patients had rhinitis or pharyngitis. The duration of symptoms averaged four days; in two patients, diarrhea lasted 9 days and in one, 14 days. Nine patients were classified as "severely" ill for a day or two, and three had mild attacks. The word severe is used only in relation to the majority of cases of mild disease in ambulatory patients. Severe bacillary dysentery as described in textbooks, with prolonged fever, prostration, blood, pus, and mucus in the stools, and sequelae did not occur. A composite record of the fever curves of 11 patients is illustrated in chart 2. Streptomycin, aureomycin, chloramphenicol, or terramycin were given to one or two patients each. The short duration of the acute stage in all patients did not allow critical evaluation of antibiotic therapy. Several cases are cited as examples of the degrees of severity encountered.

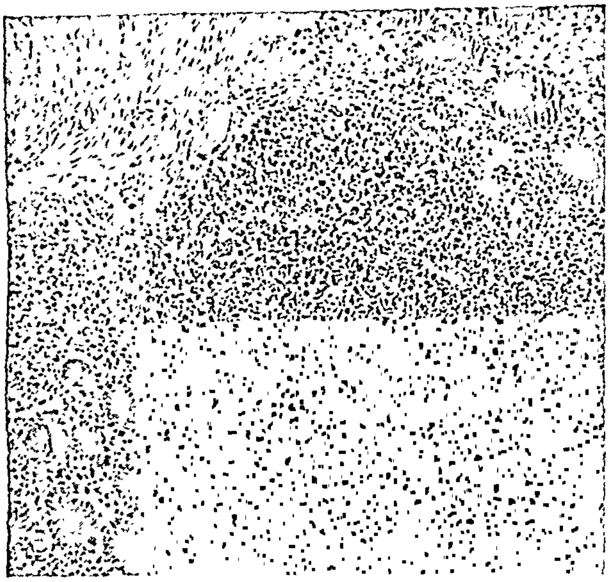

Fig. 1 (patient B. D.).—Mild inflammatory reaction, with edema, congestion, superficial focal areas of hemorrhage, and infiltration of plasma cells and polymorphonuclear cells of the rectal mucosa in a patient with bacillary dysentery. The epithelium was eroded in a few areas. Some of the crypts contained leukocytes. A hyperplastic lymph node in the mucosa is shown (× 88.55).

REPORT OF CASES

Severe Disease.—B. D. noticed nasal obstruction, rhinorrhea, sore throat, and cough between Sept. 9 and 17. On Sept. 15, she had sudden colic, nausea, and six watery stools. The next day she vomited, felt chilly, and had diarrhea, but she continued to work. She became so ill that she entered the hospital on Sept. 17, with a temperature of 100 F. She appeared ill, had nasal obstruction, rhinorrhea, and an injected edematous pharynx. The leukocyte count was 7,000. The number of leukocytes in a sample of stool was estimated as 70 per microscopic field. During the next three days, her fever rose to 103 F. Seven to 13 watery stools a day required two intravenous infusions of 1,000 cc. of isotonic solution of sodium chloride and 5% glucose for rehydration. The leukocyte count was 12,000. On the fifth day, her temperature again rose to 102 F, and rehydration was necessary. Terramycin was given between Sept. 21 and 25, without obvious effect; diarrhea persisted for 14 days.

Sigmoidoscopy performed on Sept. 19, revealed perianal inflammation and moderate inflammation up to the limit of vision, 17 cm. The mucosa was dusky and erythematous, with moderate edema. There were numerous small petechiae but no ulcers. Biopsy revealed inflamed rectal mucosa (fig. 1).

A. S. had a headache on Sept. 14; this was soon followed by three diarrheal stools and colic, nausea, and vomiting. On admission to the hospital on Sept. 15, she had a temperature of 101.5 F that rose to 104 F but lasted only a day; her pulse rate was 120 to 140 per minute. Diarrhea persisted; she vomited four times and was dehydrated. The leukocyte count was 7,000. About 60 leukocytes per microscopic field were present in a sample of stool. An intravenous infusion of 1,000 cc. was given. On Sept. 16, her temperature became almost normal, but dehydration from diarrhea again required intravenous infusion. Recovery occurred after nine days. Sigmoidoscopy on Sept. 20 revealed proctitis with diffuse granularity, erythema, and many submucosal hemorrhages. The mucosa bled easily. Biopsy showed moderately severe inflammation (fig. 2).

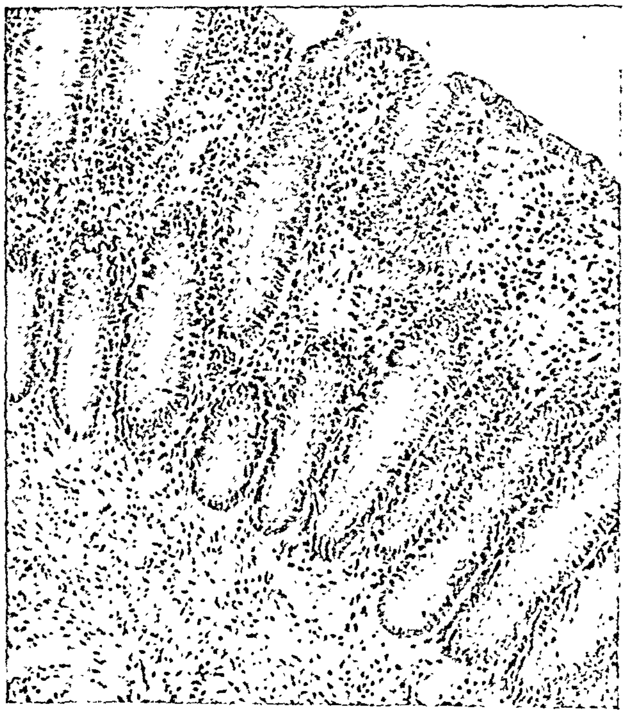

Fig. 2 (patient A. S.).—Moderate inflammatory response of the rectal mucosa as seen in a patient with bacillary dysentery. The supportive tissue is edematous and shows punctate hemorrhages, polymorphonuclear leukocytic invasion, engorged capillaries, and an occasional hyperplastic lymph follicle In many areas the surface was denuded of epithelium (× 100).

Mild Disease.—E. S. had sudden abdominal pain, colic, and diarrhea on Sept. 16. She suffered from nausea and had four watery stools during the night. She was admitted to the hospital on Sept. 17, with a temperature of 101 F and a pulse rate of 120 per minute. She vomited once. Her abdomen was tender, and peristalsis was audible. She had seven watery stools on Sept. 18, and two on Sept. 19. About five leukocytes were seen in a microscopic field of stained stool. The illness lasted three days.

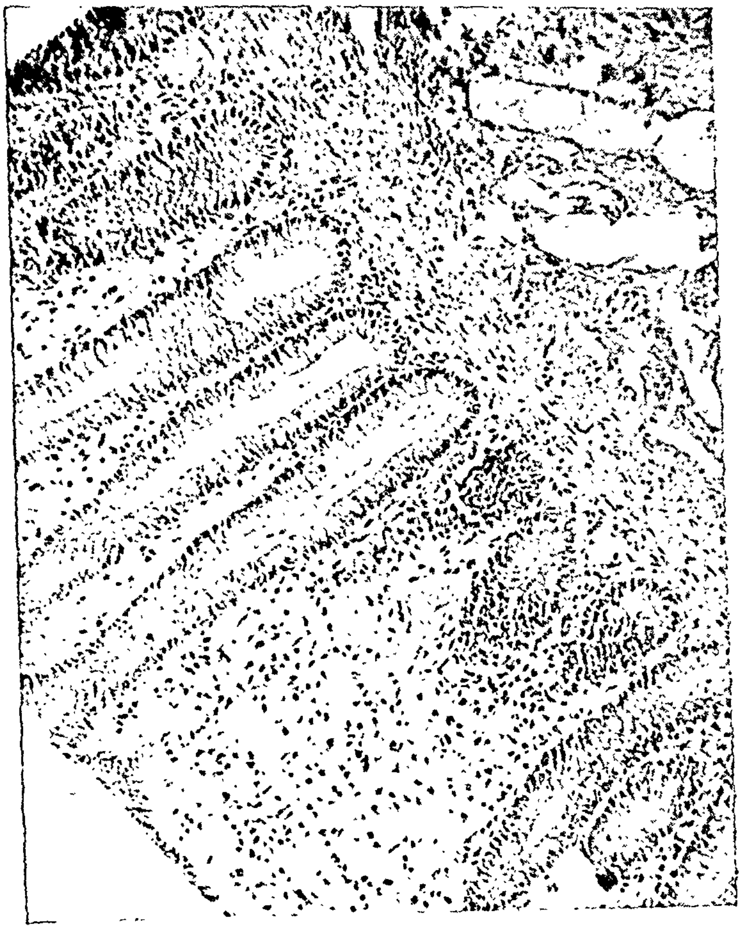

Fig. 3 (patient I. I.).—Shigella was not found in this patient with dysentery that was probably viral in origin. A mild, inflammatory reaction of the rectal mucosa with much edema, engorgement of vessels, punctate hemorrhages, and a diffuse infiltration of plasma cells and polymorphonuclear cells can be seen (× 100).

VIRAL DYSENTERY

The onset of disease in 11 patients from whose stools Shigella was not cultivated occurred between Sept. 14 and 20. For comparison with those of proved bacillary dysentery they are grouped tentatively as cases of viral dysentery (chart 2). Shigella, of course, may have been operative but undetected in some. Variation in grades of severity characterize both diseases and renders clinical diagnosis impossible in individual cases. The clinical characteristics of the cases grouped here were similar to those described for the severe form of viral dysentery [1a]; the temperature did not exceed 99 F in six patients; it reached 104 F in only one and lasted more than two days in only two patients, in contrast to those from whom Shigella was isolated (chart 2). All the patients had diarrhea; colic was noted in nine, nausea in seven, vomiting in seven, and shaking chill in six, chilliness in five, and a temperature over 99 F in five. Leukocytosis of 12,000 and 13,000 occurred in two. Eight had rhinitis and/or pharyngitis. Diarrhea lasted from 3 days in two patients to 12 days in one. The disease in patients ill before and after the middle of September was like that described as viral dysentery by many observers and need not be repeated in detail. All were ambulatory. Nasal obstruction, rhinorrhea, sore throat, or cough were noted in 26% of the patients.

REPORT OF CASES

Severe Disease.—I. I., on Sept. 16, suddenly noted colic, which was shortly followed by a liquid stool and abdominal pain. She suffered from anorexia and passed five watery stools. The next day, she had anorexia, intermittent colic, and six watery stools; during the night, 12 stools were passed. She vomited but kept working. A shaking chill occurred on Sept. 18, with a temperature of 101 F, giddiness, and weakness. She was sent to bed with a temperature of 102 F and a pulse rate of 120 per minute and was given two infusions for rehydration. The nasal and pharyngeal mucosa were injected. She was giddy and had hyperperistalsis and abdominal tenderness. Diarrhea persisted for two days, necessitating four more intravenous infusions. She recovered on the fifth day.

Sigmoidoscopy on the fourth day revealed irregularly distributed areas of inflammation and moderate edema of the mucosa. There were many submucosal ecchymoses. Biopsy showed inflammation, congestion, and edema of the mucosa (fig. 3).

Mild Disease.—S. D. had a sore throat on Sept. 17. The next morning she had sudden colic and one loose stool. Thereafter, she had anorexia and 16 watery bowel movements in 24 hours, but she continued to work. On the third day, there were eight stools, nausea, vomiting, weakness, and general aching but no fever. She was sent to bed on Sept. 20. The nasal and pharyngeal mucosae were injected. The leukocyte count was 6,000. She vomited, but the diarrhea ceased, and she returned to duty. Sigmoidoscopy revealed the rectal mucosa to be slightly reddened, and biopsy showed mild inflammation (fig. 4).

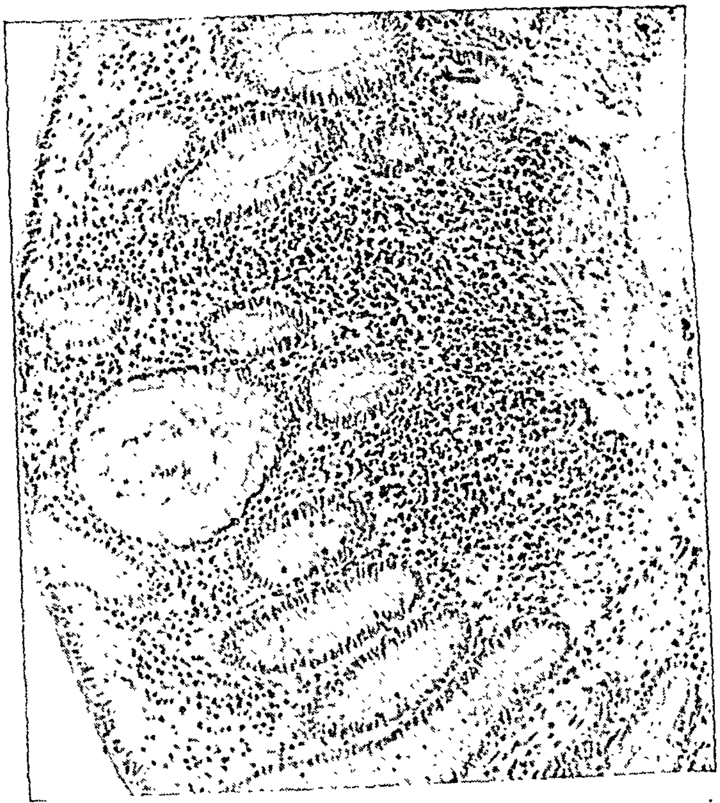

Fig. 4 (patient S. D.).—Inflammation of the rectal mucosa as seen in a patient with mild dysentery, probably viral. The epithelium is hyperplastic in areas. Distended glands are separated by edema of the supportive tissue. Infiltration of tissue with plasma cells and an occasional polymorphonuclear cell can be seen. There is engorgement of blood vessels in mucosa and submucosa (× 100).

COMMENT

According to the observations described, viral dysentery again appeared to be rampant in autumn, but, in the group studied, the sudden peaking over five days, as shown in chart 1, was caused by the coincidence of a small epidemic of bacillary dysentery. Similar circumstances were observed in three epidemics described by English physicians.[5] Another extensive epidemic of diarrheal disease, which lasted over a month in a city in Kansas, in 1942, was regarded as water-borne bacillary dysentery because Shigella was isolated from a few patients;[6] however, a similar mild disease prevalent in nearby communities was called "intestinal influenza."

In the outbreak described, shigellae probably were spread by an undetected carrier who, over a short period, contaminated food served in the nurses' dining room. Probably all nurses who partook of the food ingested an inoculum, but only a few became ill, and Shigella was recovered from 12. Viral dysentery apparently was present among the nurses and may have predisposed some of those who had it to superinfection with Shigella. Otherwise, Shigella may not have been invasive. Other mild enteric disturbances induced by catharsis or by avitaminosis[7] are known to predispose to cholera and to bacillary dysentery. In the healthy volunteers, of Shaughnessy's experiments,[8] large inoculums of Shigella often failed to cause dysentery, and, in many instances, caused only mild, brief diarrhea within 24 hours. There is reason to suppose, therefore, that intestinal disturbance caused by viral dysentery, at times, may render persons susceptible to shigellosis in a manner in which minor viral infections of the respiratory tract predispose to bacterial pneumonias. That such is not always the case is indicated by information furnished by Dr. William W. Frye. A characteristic, large epidemic of presumed viral dysentery affected military personnel and prisoners of war on a Korean island in the summer of 1951. Bacillary dysentery was common in Korea at the time, but it was not detected among the victims of viral dysentery.

The frequency of nasopharyngitis in patients with viral dysentery, as noted in the epidemics of 1943, 1944,[1a] the present one, and by Bradley,[9] Enders,[2] and Beadenkopf[10] is confusing. Many observers make no mention of it or note its absence. The respiratory tract was suggested as a possible portal of entry,[1a] and, in experiments, mild diarrheal disease seemed to be transmitted to volunteers by the inhalation of nebulized, filtered oropharyngeal secretions from patients.[1b] It is not clear, at present, whether nasopharyngitis is an integral part of viral dysentery. If nasopharyngitis represents a separate infection, three diseases were concurrent in the present epidemic. Influenza, colds, and viral dysentery apparently concurred in an epidemic in Los Angeles in 1947.[11] Further uncertainty is added by the occurrence of the opposite circumstance, namely, the presence of gastrointestinal disorders in about 10% of patients with minor infections of the respiratory tract.[12]

Differentiation between viral and bacillary dysentery obviously is difficult. Epidemiologically, "peaking" is unusual for viral dysentery, but it may occur,[13] and bacillary dysentery may appear in low-grade, prolonged epidemics. In this study it is not likely that Shigella was implicated in the many cases scattered throughout the city and its environs during the autumn. Except by the isolation of Shigella, it was impossible, in individual cases, to differentiate the two diseases. The severe form of bacillary dysentery, often portrayed as "typical" in textbook descriptions was not seen, and the symptoms in most cases[14] were the same as those of viral dysentery. However, as suggested by the clinical description and illustrated in chart 2, Shigella was apt to cause severer disease with higher fever, as was also noted by Martin and Wilson.[4d]

The pathological changes in the rectal mucosa are not specific. The mild inflammatory response observed in viral dysentery is indistinguishable from that in mild bacillary dysentery and is the same in Salmonella infection.[15] Yet a predominance of plasma cells or lymphocytes may be more suggestive of a viral than of a bacterial infection. The mild inflammation may not reflect changes possibly present higher in the intestinal tract. They are similar, however, to those in the small intestine in fatal cases described by Britten.[4i] Evidence of inflammation in the intestine may be caused partly by the irritation of hyperperistalsis and in the pharynx by vomiting.

As illustrated by the experience described, diagnosis depends on the accuracy of bacteriological procedure. Bacillary dysentery would not have been diagnosed had dependence rested on the first negative reports from the general laboratory. Shigella was detected only after samples of stools were submitted to experts. Until the cause of viral dysentery is discovered and etiological diagnosis is made possible, differentiation rests on the nature of the epidemic and on the predominance of mild cases suggesting a viral cause on one hand and on the greater number of severer cases and the isolation of Shigella on the other.

SUMMARY

As in previous years, an outbreak of viral dysentery occurred in the early autumn among hospital personnel, students, and the community at large and lasted over a month. A short epidemic of Shigella sonnei colitis limited to nurses was superimposed. Viral dysentery may render patients susceptible to enteric bacillary infections, as viral infections of the respiratory tract predispose to bacterial pneumonia. Differentiation between viral and bacillary dysentery rests on the nature of the epidemic, the greater severity of shigellosis, and the isolation of Shigella.

A CLINICAL GUIDE TO PROGNOSIS IN STRESS DISEASES

Beatrice B. Berle, M.D., Ruth H. Pinsky, M.A., Stewart Wolf, M.D.
and
Harold G. Wolff, M.D., New York

A guide to prognosis in stress diseases has been devised on the basis of experience in the treatment of 739 patients in the Medicine A clinic of the New York Hospital. Its validity has been tested in three selected groups of patients with essential hypertension, migraine, and asthma. An earlier report of the experience of this clinic [1] emphasized a description of the general methods of treatment used, an appraisal of the effectiveness of each, and an estimation of the important prognostic factors. In the present report a more systematic appraisal of prognosis is offered in the form of a score sheet on which a patient can be rated after the first three or four visits to the physician.

Most of the patients were seen at approximately weekly intervals during the first month of attendance at the clinic and at biweekly or monthly intervals thereafter. The average number of visits per patient was 15; the average duration of treatment was nine months. Among these patients 90 had essential hypertension, 62 irritable colon, 67 bronchial asthma, 54 headache due to sustained muscle contraction, 52 migraine, 35 peptic ulcer syndrome, 25 urticaria, 21 vasomotor rhinitis, and 18 ulcerative colitis.

The first step in construction of the scale was to summarize the data in each case under 49 main headings as follows:

Age
Admission information (sex, marital status, and employment)
Race, nationality
Religion
Doctors in charge
System review
Past medical history
Diagnostic headings
Family (general information)
Spouse
Children
Whether contraception used and what type
Childhood
School attendance
School adjustment
Mother
Father
Family values
Siblings
Employment
Employment adjustment
Sex, childhood
Sex, adult
Housing
Character attitude
Character behavior
Estimate of previous life experience
Stress situation in past
Previous treatment
Life situation precipitating present illness
Estimate of information
Duration of illness
Intensity of illness
Patient's attitude toward illness on admission
Patient's attitude toward illness during treatment
Patient's attitude toward treatment on admission
Patient's attitude toward treatment during course of treatment
Course
Mood during course
Therapy by physician
Therapy by social workers
Reasons for leaving clinic
Result on leaving clinic
Appraisal of those still in clinic
Follow-up first year
Follow-up second year
Number of visits
Number of months
Clinic financial rating

These 49 headings were subdivided into 852 items that pertained to the life experience and personal attributes of the patients. The selection of these items was based on the general experience of the entire group of 18 clinic physicians and on their particular experience with the patients of Medicine A clinic over the period of three years. The appropriate item under each heading was checked by the physician in a manner suitable for analysis with an IBM machine.

Independent of the construction of the prognostic scale, an appraisal of the clinical status of each of the 739 patients was made by his physician at yearly intervals or on the patient's discharge or departure from the clinic. The rating was based on changes in signs and symptoms and changes in the way in which the patient saw himself in relation to his life problems and how he handled and reacted to them. Evidence of change in such basic attitudes was adduced from observation of the patient's responses to new situations of significance similar to those that had earlier been associated with symptoms.

On the basis of these clinical appraisals the patients were classified into three groups: 1. Unimproved; these patients displayed no change in either symptoms or attitudes. 2. Moderately or symptomatically improved; these patients displayed a lessening or absence of symptoms without change in basic attitudes. 3. Basically improved; these patients not only were symptomatically improved but displayed a change for the better in their way of dealing with problem situations. The 739 patients fell into the three groups as follows: unimproved, 249, or 34%; symptomatic improvement, 311, or 42%; and basic improvement, 179, or 24%.

These clinical progress appraisals were entered on IBM cards together with the data on life experience and personal attributes as noted above. The various categories, unimproved, symptomatically improved, and basically improved, were then analyzed by the IBM sorting machine so that we might determine which of the coded items were most prevalent in each. Whenever there was a correlation between one of these items and the percentage of patients that fell into the improved groups, the item was selected as possibly significant. The number of items was reduced until those that appeared to be the most significant remained. The prognostic scale was made up of these remaining items, which were weighted in a more or less arbitrary way. It was not possible to evaluate statistically the significance of the various correlations, in view of the extreme variability in numbers and often the very small numerical differences. In addition to the items selected from the code, certain others of presumed significance were arbitrarily added and suitably weighted on the basis of the general clinical impression of the physicians involved.

Groupings were made under three main headings: (1) objective data relating to such items as the patient's age, social status and past medical history (20 points); (2) factors concerning the patient's family and interpersonal

---

relationships obtained from verbatim statements made by the patient (30 points); and (3) evaluations of the patient's past performance, personality structure, and attitude toward his illness, made by the physician (40 points). Table 1 shows the prognosis scale form, with an example of how one patient was scored.

Certain items commonly considered of prognostic importance did not show a positive relationship with clinical appraisals. These items included the sex of the patient, position of the child in the family, bottle or breast feeding, nail biting, night terrors and enuresis in childhood, and the number of visits to the clinic-or the frequency or interval between visits. The following factors were used in making up the prognostic scale.

TABLE 1.—*Prognostic Scoring of a Patient in the Group Studied*

Objective Data	Maximum Score	Actual Score	Comment
Age, up to 40 yr.	2	2	Age 34
Not divorced or separated	2	2	Married
Third generation American, white, gentile	2	2	American family both sides several generations; gentile
High school education complete	2	2	
Both parents living at home until patient was 12 yr. old	4	4	Father died when patient was 18; mother still alive
No surgical treatment for symptoms	2	0	Caldwell-Luc operation in past
No previous formal psychiatric care	2	2	
Steady employment	2	2	Employed 15 yr. same company
Duration of present illness less than 5 yr.	2	0	Onset of asthma 14 yr. previously
Total	20	16	
Previous health good	1	1	Well until onset of asthma
Some religious education	1	1	Family members of parish (religion no source of conflict)
Emotional support from both parents	4	2	Father and mother "fine people"; mother hypercritical, lives with patient
Congenial siblings	2	1	Brother "more successful"; many tastes in common
Emotional support from spouse	2	2	Wife most understanding and helpful
Sexual compatibility with spouse	2	2	
No serious sexual problem	3	2	One extramarital affair with conflict
Spouse adequate economic provider *	2	..	Not applicable
Children not rejected	2	2	Adopted child after death of own son
No housing problem	2	2	Five-room apartment
Occupational satisfaction	2	2	Proud of his work
Congenial working conditions	2	1	Difficulties with boss and fellow workers
Moderately adequate salary	2	2	Able to meet rent and food costs and furnish home
Goal	3	3	Hope of regaining health and buying home
Total (females) (males)	30 28	23	

Objective Data	Maximum Score	Actual Score	Comment
Evidence from past performance: Not exaggerated sensitivity to traumatic situation Good interpersonal relationships (including sexual) Evidence that the activities, achievements, and other life experiences have afforded satisfaction	10	5	Adoption of child after death of first Immature handling of sexual problem, mother, and fellow workers Job satisfaction
Evidence from personality structure: Moderate flexibility Minimal and short-lived hostility Capacity to face and solve personal problems Active participation in the give and take of daily affairs Moderate orderliness and reliability Good judgment and evidence of adequate discrimination regarding human values and goals	10	5	Stubborn Nurtures small hurts Inability to face or resolve dependency; hostility conflict Reliable in meeting financial responsibilities Reasonable life ambition
Prevailing attitudes of the patient toward illness and his problems at time of admission to clinic: Recognition of failure of present patterns of adjustment and willingness to adopt others Willingness to consider possibility that life stress, attitudes, and feeling states are relevant to the illness Confidence in physician, hospital, and its methods Capacity and willingness to assume responsibility in treatment	10	6	Desperate Willing to try anything This hospital last resort Capacity to assume responsibility for treatment doubtful
Extent to which a specific aspect of the life situation was a factor in precipitating the patient's illness: Extent to which this specific feature is modifiable with regard to the involved person, other persons, and circumstances	10	5	No specific life situation apparently related to onset of illness; wife, child, and job considered assets; mother considered a liability
Total	40	21	

* Scored only for female patients.

OBJECTIVE DATA

The following objective data were rated two points each, except where otherwise indicated.

Age, up to Forty Years.—Patients in their forties and fifties (185) were the ones who showed the least evidence of improvement. The greatest degree of change was found among those from 14 to 40 years of age (537). Those in their sixties (12) and seventies (6) were too few to permit evaluation of them as a group, although great improvement was observed in some.

Not Divorced or Separated.—Only 5% of the 739 patients were either divorced or separated. However, in these two groups (divorced and separated) the percentage of no improvement was 47 and 40, respectively.

Third Generation American, White, Gentile.—The obviously increased adjustment problems of subjects who are not of the dominant group in our society prompted the assignment of two points to third generation American, white, gentile, although the preponderance of patients meeting these criteria among the improved group was slight.

High School Education Completed.—There was a slight preponderance of those with completed high school education among the improved group.

Both Parents Living at Home Until Patient Was Twelve Years Old (Four Points).—Twenty per cent of the patients had suffered the loss of one parent at an early age. In these patients the degree of improvement was much less than for the group as a whole.

No Surgical Treatment for Symptoms.—There were 120 patients among the 739 who had never had any surgery; the incidence of improvement among these was much higher than among the 117 who had had one or more operations for the symptoms under consideration.

No Previous Formal Psychiatric Care.—The proportion of improved patients was less among the 44 who had had previous psychiatric care than among the group as a whole.

Steady Employment.—There were 412 patients who were old enough to have been employed for several years and from whom adequate past employment histories could be obtained. The proportion of improved patients among the 280 who had been steadily employed was greater than that among the 132 who changed jobs frequently.

Duration of Present Illness Less Than Five Years.—There were 154 patients in whom symptoms referable to the present illness were of less than one year's duration on admission to the clinic; 75% of these were in the improved group. Of the 224 patients whose illness had lasted more than one year but less than five years, 69% were improved. In the 361 whose illness had lasted more than five years, only 63% were improved.

DATA DEPENDENT ON PATIENT'S INTERPRETATION

The following criteria distinguished those patients who showed the greatest improvement. The categories reflect the patient's own interpretation of his background and experience.

Previous Health Good (One Point).—Those who had had the usual childhood illnesses but no serious diseases or traumatic accidents were among those who showed most improvement.

Some Religious Education (One Point).—Among the improved, those patients who had had some religious education appeared in greater numbers. Fewer of those with a "strict" religious background (attendance at parochial schools) and family stress on religious observation or with no religious education and no family adherence to religious custom were found among the improved group.

Emotional Support from Both Parents (Four Points).—By emotional support from both parents was understood loving care of the child combined with predictable and consistent discipline in keeping with prevailing cultural patterns.

Congenial Siblings (Two Points).—This implied fondness among brothers and sisters, with competition for parental affection and recognition at a minimum.

Emotional Support from Spouse (Two Points).—Credit was given for evidence that the spouse customarily endorsed the patient in public and private and for evidence of mutual interdependence with a minimum of belittling criticism.

Sexual Compatibility with Spouse (Two Points).—Credit depended on an expression of satisfaction by the patient in his intimate sexual relations with his or her spouse.

No Serious Sexual Problem (Three Points).—Serious sexual problems were defined as deviations from the accepted form of sexual behavior in the form of homosexual relations or unusual sexual appetites when they were sources of anxiety and guilt.

Spouse Adequate Economic Provider (Two Points).—This item was included only for the female married patient on the basis of her evaluation of her husband's effectiveness as a provider.

Children Not Rejected (Two Points).—Evidence of rejection included both overt and implicit expression of hostility on the part of patients toward their children.

No Housing Problem (Two Points).—In evaluation of the patient's housing situation, the yardstick was not the standard of housing authorities or the physician, but the patient's own appraisal of his home surroundings. Living in a substandard tenement in a poor neighborhood, if not indicated by the patient as being a source of conflict or disturbance, was not considered a housing problem.

Occupational Satisfaction, Congenial Working Conditions, Moderately Adequate Salary (Two Points Each).—The exact nature of the work done, hours of work, salary obtained, and attitude toward fellow workers and superiors provided evidence of the patient's attitude toward his work. Satisfaction and pride in terms of individual needs were stressed. Scoring is intended to reflect the patient's attitudes toward various aspects of his working life. The score was not based on Department of Labor standards or on the physician's appraisal of the job and salary.

DATA DEPENDENT ON PHYSICIAN'S INTERPRETATION

Many individual attributes were appraised by the physician and found relevant to the patient's course in the clinic. These separate items have been classified into four main groups: (1) past performance, (2) personality structure, (3) attitude toward the present illness, and (4) potential modifiability of the current situation. Each group is weighted 10 points.

Past Performance.—In the evaluation of the patient's reaction to stress, the manner in which adversity had been met in the past was taken into account. The capacity for entering into and maintaining warm interpersonal relations and achieving a sexual adjustment was credited under the category of past performance. Also included was an estimate of the degree to which the patient had been able to derive satisfaction from the vocations and avocations of everyday life.

Personality Structure.—This was evaluated through an analysis of the balance of drives and characteristic behavior as revealed by a review of the life history as a whole and through a discussion of ordinary incidents in daily life. Evidence was sought to illustrate the patient's degree of flexibility and capacity to adapt to change. Indications of extreme hostility, overt or unexpressed, were considered of poor prognostic significance, especially if there were instances of asocial behavior.

A favorable interpretation was placed on indications of resourcefulness and stamina in dealing with personal problems as well as evidence of participation in civic, club, and church activities. Moderate but not excessive orderliness and reliability were also scored as good signs; finally, credit was given for indications of maturity of values and goals.

Attitude Toward the Present Illness.—The physician's evaluation of the patient was focused on an appraisal of the patient's attitude toward his illness. A "declaration of bankruptcy" in which the patient indicated a recognition of failure of past patterns of adjustment and his need for help in making new ones was considered the most favorable attitude. Another helpful indication was the willingness to consider the pertinence of stressful life experiences as factors in bringing about illness. Confidence in the physician and the hospital and a capacity and willingness to assume some responsibility in treatment were other items in this group.

Modifiability.—Attempts were made to determine whether the onset of the patient's illness was contemporaneous with an environmental change, i. e., change of job, school, home environment, death or illness of a parent figure, or return from military service. If such were the case, the possibility of manipulating the environmental situation for the individual patient was evaluated.

METHOD OF APPLYING SCALE

The scoring of one patient is shown in table 1. He achieved 69%, and it was predicted that he would achieve symptomatic improvement without basic change. At the time of writing he had been seen in the clinic over a period of 27 months on 42 occasions—14 in the last 12 months as contrasted with 10 in the first 3 months. His course was a fluctuating one, varying not with the seasons but with the stressful situations at home. He had not missed more than three days at work during this period, compared with the weeks and months of absence in previous years.

TABLE 2.—*Comparison of Prognostic Scale Results with Appraisals of Patients' Clinical Status* *

Results	No. of Patients	Prognosis Rating: Range	Prognosis Rating: Average
Migraine †			
Group 1	18 (35%)	41-61	52
Group 2	30 (58%)	60-74	65
Group 3	4 (7%)	79-83	81
Hypertension ‡			
Group 1	37 (41%)	25-62	51.8
Group 2	44 (49%)	51-58	63
Group 3	9 (10%)	80-89	82.5
Asthma §			
Group 1	18 (27%)	25-59	49.5
Group 2	33 (49%)	52-65	61
Group 3	16 (24%)	70-83	80

* Group 1, unimproved; group 2, symptomatically improved; and group 3, basically improved.

† Fifty-two patients. ‡ Ninety patients. § Sixty-seven patients.

TESTING OF THE PROGNOSTIC SCALE

The scale was applied to 67 patients with asthma, 52 with migraine, and 90 with essential hypertension treated by this medical group. Patients with these diagnoses were selected because they have a well-defined clinical syndrome in which changes in severity can be fairly reliably appraised. When the prognostic scale results were compared with the separately recorded appraisals of the patients' clinical status, a close correlation was observed (table 2).

The 73 patients with hypertension, asthma, or migraine headaches, who averaged a score below 60% on the prognosis score, were found in the unimproved group; only 5 who had been considered unimproved scored over 60%. The symptomatically or moderately improved group comprised 107 patients whose average score was 63%. Only one patient in this group scored above 73%, while five scored below 60%. In the third group of 29 basically improved patients the average score was 81%, with only one scoring below 71%.

Because in retrospect the criteria for improvement or lack of it appeared somewhat rough and not in sufficient detail, an attempt was made in the 90 cases of hypertension to appraise more carefully and in greater detail the clinical status at the time this report was prepared.

The 90 patients fell into four groups: Group 1, or "no change," included 37 patients, or 41% of the total. These patients showed no detectable change in blood pressure, in basic attitudes as defined earlier, or in other stress reactions.

Group 2, or "minor change," was made up of 38 patients, or 41% of the total. This group was further divided into three subgroups: subgroup A, with blood pressure the same, basic attitude only slightly changed or the same, and other stress reactions significantly reduced; subgroup B, with blood pressure lower, basic attitude the same, and other stress reactions reduced; and subgroup C, in which blood pressure became normal, other stress reactions were reduced, but the basic attitude remained the same.

Group 3, or "moderate change," included eight patients, or 9% of the total. In these the blood pressure was the same or slightly reduced, basic attitudes were moderately altered, and the other stress reactions were definitely reduced.

Group 4, or "major change," was made up of nine patients, or 10% of the total. In these the blood pressure had fallen to normal, the basic attitude was much altered, and other stress reactions were greatly reduced.

From an examination of these results, reported in detail in another publication,[2] it would appear that some alteration could be anticipated as a result of a constructive physician-patient relationship in approximately 60% of patients with essential hypertension who complain of symptoms. Most of these, or about 40% of the total, were those changed in that they had fewer symptoms, less outward expression of anxiety, and greater tranquillity than before the experience, although in most of these the blood pressure was not appreciably lowered. However, even in this group a slight lowering of the blood pressure was associated with a decline in symptoms and a restitution of some degree of tranquillity.

The symptom loss was not directly related to a change in the blood pressure level, although in group 4 the loss of symptoms was accompanied by a lowering of the blood pressure. Tremulousness, insomnia, and restlessness were most readily modified. Headache, mainly related to more or less superficially suppressed anger or frustration and to fatigue, was also modifiable and, as mentioned elsewhere,[3] was not related to the level of the blood pressure. These reactions were more easily modified than the blood pressure elevation, which was associated with more deeply repressed anger or frustration. Thus a consideration of life situations, attitudes, and feeling states reduced or eliminated symptoms and other stress reactions in the majority of those with essential hypertension and reduced the blood pressure to normotensive levels in a few. The prognostic scale was applied to the revised data obtained from the more detailed analysis of the clinical state of each patient with hypertension. The results corresponded even more closely than those listed in table 2.

[3] Wolff, H. G.: Headache and Other Head Pain, New York, Oxford University Press, 1948.

blood pressure was 17 mm. and in diastolic 12 mm. When only the patients who had a decrease, whether uniphasic or biphasic, in blood pressure following the intravenous administration of regitine® were considered the mean fall was 20 mm. systolic and 14 diastolic (table 2).

Table 2.—*Effects of Regitine® Given Intravenously on Blood Pressure of 107 Patients Who Did Not Have Pheochromocytoma*

	Mean Blood Pressure or Changes, Mm. Hg		Percentage of Patients Showing Change in Blood Pressure	
	Systolic	Diastolic	Systolic	Diastolic
Basal	178 ± 3.3	119 ± 21	..	..
Rise	17 ± 1.0 *	12 ± 0.6 *	74 †	62 †
Fall	20 ± 1.6 *	14 ± 0.8 *	64 †	68 †

* Diphasic responses included; all falls or all rises were included as indicated. The pure depressor responses were excluded from calculating average pressor responses and vice versa.

† Some patients showed both a fall and rise in blood pressure after administration of regitine.®

Only rarely did the fall in blood pressure exceed 35 mm. systolic and 25 diastolic except in cases of proved pheochromocytoma; however, in a few instances of essential hypertension depressor responses of this magnitude did occur; these will be discussed separately as false positive reactions.

Effect on Pulse and on Subjective Symptoms.—Regitine® when given intravenously increased the pulse rate 96% of the 107 patients. The mean increase in pulse rate was 17 beats per minute. A few of the patients experienced a mild sensation of warmth with minimal flushing of the skin after regitine® was administered intravenously. There were no serious untoward side-effects.

Comparison with Piperoxan.—Sixty-one hypertensive patients received both regitine® and piperoxan intravenously. The difference in the effects of the two drugs was striking. Whereas regitine® produced minimal side-reactions, piperoxan almost invariably produced unpleasant subjective sensations of heat, palpitation, and apprehension with objective signs of flushing and sweating. The administration of piperoxan to one patient had to be discontinued because it produced severe substernal pain, yet the patient tolerated regitine® without difficulty. In 97% of the patients, piperoxan produced a pressor response of more than 5 mm., which averaged 34 mm. systolic and 21 mm. diastolic. Regitine,® on the other hand, produced a pressor response in only 75% of the patients and the average rise was only 17 mm. systolic and 12 mm. diastolic (table 3). In only three patients did regitine® have a greater pressor effect than piperoxan. Figure 1 compares the blood pressure responses of two patients to whom regitine® and piperoxan were given.

Table 3.—*Comparison of Effects of Regitine® and Piperoxan Given Intravenously on Blood Pressure of 61 Patients with Hypertension*

Blood Pressure After Intravenous Injection	Mean Blood Pressure or Changes, Mm. Hg		Percentage of Patients Showing Change in Blood Pressure	
	Systolic	Diastolic	Systolic	Diastolic
Regitine®				
Basal	193 ± 2.8	127 ± 2.1	..	..
Rise	17 ± 1.1	12 ± 0.8	75	66
Fall	22 ± 2.0	14 ± 1.0	64	69
Piperoxan				
Basal	196 ± 2.9	126 ± 2.2	..	..
Rise	31 ± 1.8	21 ± 1.4	97	93
Fall	14 ± 1.2	9 ± 1.0	33	30

False Positive Reactions.—Regitine,® whether it is given intravenously or intramuscularly, tends to depress the blood pressure of patients with essential and renal hypertension. Usually the blood pressure of these patients is reduced less than 35 mm. of mercury systolic and 25 diastolic. In 4 of the 107 patients studied, the fall in blood pressure was marked enough after the intravenous administration of regitine® to arouse suspicion that excess circulating pressor substance might be present.

Case 1.—A woman, 27 years old, who had terminal nephritis, retinopathy (group 4 [13]) and uremia, evidenced by 250 mg. of urea per 100 cc. of blood, was given 5 mg. of regitine® intravenously. Within two and a half minutes her blood pressure fell from a basal level of 290 mm. of mercury systolic and 188 diastolic to 240 mm. systolic and 156 diastolic. The response to piperoxan was equivocal. Postmortem examination revealed chronic glomerulonephritis but no evidence of a pheochromocytoma.

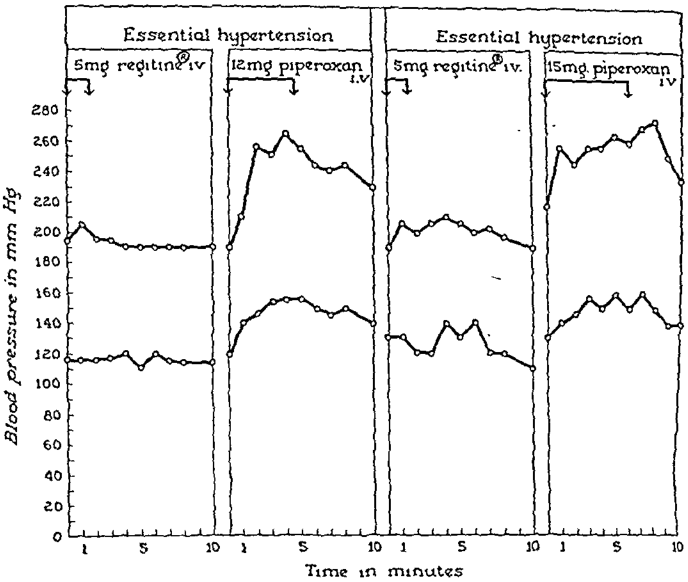

Fig. 1.—Comparison of the changes in blood pressure of two patients after the intravenous administration of 5 mg. of regitine® and later of 12 and 15 mg. of piperoxan respectively.

Case 2.—A woman, 50 years old, gave a short history of paroxysmal attacks of headache and hypertension on admission. Two histamine tests reproduced the headaches, but the elevation in blood pressure following administration of histamine was just about equal to that obtained with the cold pressor test. On one occasion when the patient was observed in a spontaneous attack, she had received 200 mg. of meperidine (demerol®) hydrochloride in the preceding three hours and appeared heavily sedated. Five milligrams of regitine® were administered intravenously, and within three minutes the blood pressure fell from 180 mm. systolic and 90 diastolic to 120 mm. systolic and 66 diastolic. Her headache was temporarily relieved. On two other occasions, when the patient had not received previous sedation, regitine® had no depressor effect on her blood pressure during a spontaneous attack of headache or a histamine-induced attack. Results of a piperoxan test were negative. A thorough abdominal exploration failed to reveal a pheochromocytoma.

Case 3.—A woman, 59 years old, complained of exhaustion, weakness and paroxysmal attacks of constriction in the chest, numbness of the hands, and abdominal bloating. After 5 mg. of regitine® were given intravenously, her blood pressure dropped within two minutes from 210 mm. systolic and 114 diastolic to 148 mm. systolic and 90 diastolic. A similar result with regitine® was obtained on another occasion, but two piperoxan tests gave definitely negative results. An exploratory operation was not done, as her attacks were considered to be due to hyperventilation and not to pheochromocytoma.

CASE 4.—A man, 59 years old, gave a three year history of paroxysmal attacks of hypertension, dyspnea, orthopnea, apprehension, and profuse perspiration. He had a mild case of diabetes. His basal blood pressure was about 120 mm. systolic and 72 diastolic. Provocative tests using histamine, tetraethylammonium chloride, and methacholine hydrochloride failed to induce an attack. He was observed in one spontaneous attack. Unfortunately, he had been heavily sedated with ⅜ grain (0.024 gm.) of morphine sulfate 30 minutes before he was hospitalized. He had acute pulmonary edema, and blood pressure was 180 mm. systolic and 110 diastolic. Ten milligrams (instead of five) of regitine® were given rapidly intravenously, and blood pressure fell to 80 mm. systolic and 60 diastolic within two minutes. Clinically he improved rapidly. Ninety minutes later blood pressure was 90 mm. systolic and 60 diastolic, and the pulmonary edema had largely disappeared. A thorough abdominal exploration failed to disclose a pheochromocytoma.

RESULTS OF INTRAMUSCULAR TESTS

One hundred and fifty-four patients received regitine® intramuscularly. Of these five proved to have pheochromocytomas. Of the remaining 149 patients, 11 were normotensive and 138 were hypertensive. As with regitine® given intravenously there was no essential difference in the blood pressure response to regitine® of patients in either group or among patients in various groups of hypertension, so they will be discussed together.

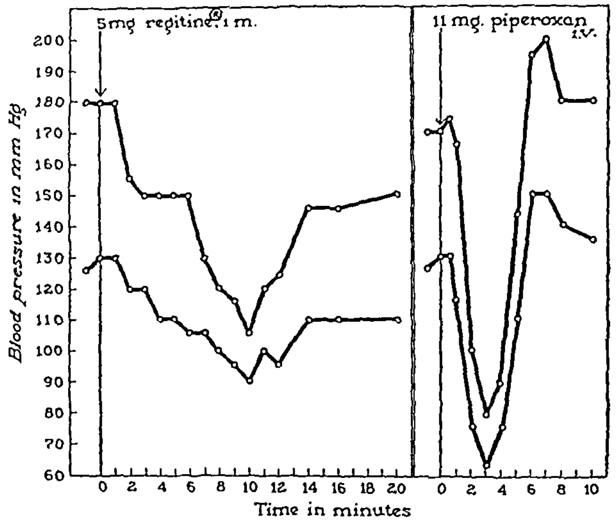

Fig. 2 (case 5).—Changes in blood pressure resulting from the intramuscular administration of 5 mg. of regitine® and on another occasion from the intravenous administration of 11 mg. of piperoxan.

Effect on Blood Pressure.—Except for a slower response following the intramuscular injection of regitine,® the effect on blood pressure was the same regardless of the route of administration (table 4). What has already been said concerning the effects of regitine® given intravenously on blood pressure, applies, in general, to that observed after regitine® was given intramuscularly. When regitine® was given intramuscularly, however, the average time for its maximal effect on blood pressure was 13 minutes, while the maximal effect was noted within 4 minutes after intravenous administration.

Effect on Pulse and on Subjective Symptoms.—The effects of regitine® given intramuscularly on pulse rate were variable. Seventy-nine per cent of the patients showed a rise in pulse rate, the average rise being only 10 beats per minute as compared to 17 following intravenous administration of regitine.® The pulse rate of 68% of the patients decreased an average of 7 beats per minute. As with the blood pressure, many of the patients showed both a rise and fall in pulse rate. None of the patients complained of any unpleasant side-effects following the intramuscular administration of regitine.®

TABLE 4.—*Effects of Regitine® Given Intramuscularly on Blood Pressure of 149 Patients Who Did Not Have Pheochromocytoma*

	Mean Blood Pressure or Changes, Mm. Hg		Percentage of Patients Showing Change in Blood Pressure	
	Systolic	Diastolic	Systolic	Diastolic
Basal...............	180 ± 3.0	116 ± 2.0	..	..
Rise...............	17 ± 0.8 *	13 ± 0.6 *	62 †	58 †
Fall...............	19 ± 1.1 *	14 ± 0.7 *	72 †	63 †

* Diphasic changes included; all falls or all rises were included as indicated. The pure depressor responses were excluded from calculating average pressor responses and vice versa.

† Some patients showed both a fall and a rise in blood pressure after administration of regitine.®

Comparison with Piperoxan.—One hundred hypertensive patients received regitine® by the intramuscular route and piperoxan by the intravenous route. The results were just as striking as when results of the intravenous use of regitine® were compared to those of piperoxan. Unpleasant symptoms that almost invariably accompanied the administration of piperoxan were entirely lacking when regitine® was given intramuscularly. The pressor response following regitine® was much less than that following piperoxan (table 5). In only 1 patient in this group of 100 was the pressor response after administration of regitine® greater than that after piperoxan.

False Positive Reactions.—Three of the 149 patients showed a depressor response following use of regitine,® which suggested that an excess amount of a pressor substance might be present in the circulating blood. In none of these three cases, however, was a pheochromocytoma proved to be present, and, therefore, the reaction must be considered false positive.

TABLE 5.—*Comparison of Effects of Regitine® Given Intramuscularly and of Piperoxan Given Intravenously on Blood Pressure of 100 Patients*

Drugs Administered	Mean Blood Pressure or Changes, Mm. Hg		Percentage of Patients Showing Change in Blood Pressure	
	Systolic	Diastolic	Systolic	Diastolic
Regitine® Given Intramuscularly

One patient, who had terminal uremia, was given regitine® intramuscularly as well as intravenously. Following the administration of 10 (instead of 5) mg. of regitine® intramuscularly, her systolic blood pressure slowly dropped from 256 mm. to 198 and her diastolic pressure from 160 mm. to 120 in 40 minutes. Although the maximal fall in blood pressure did not occur in the first 20 minutes after injection, the magnitude of the fall led us to consider this a positive reaction. As previously stated, no pheochromocytoma was found at necropsy.

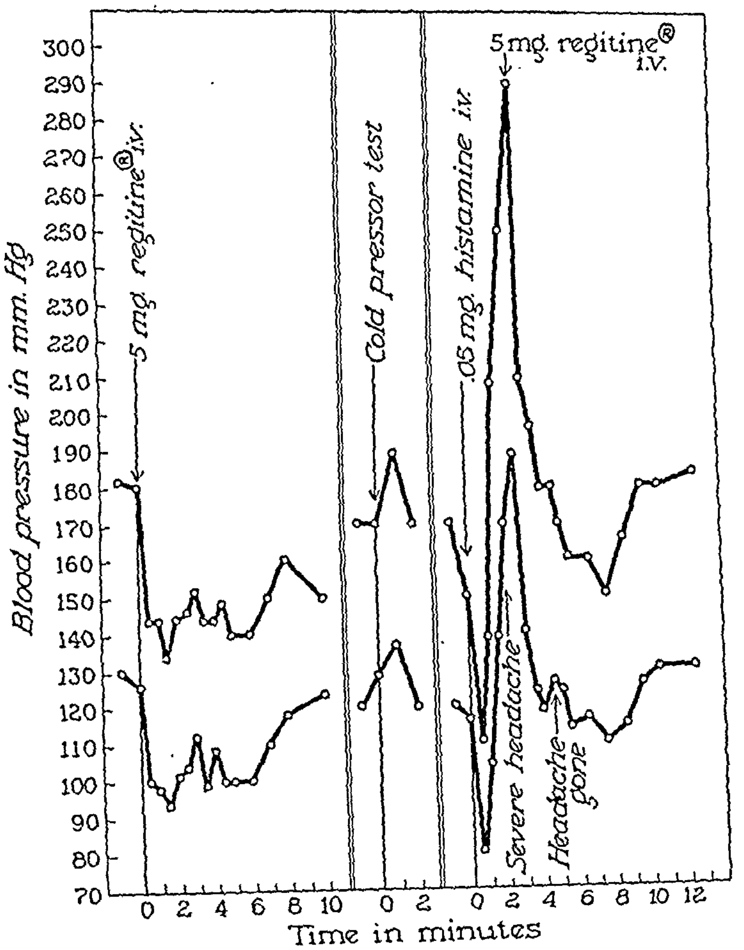

Fig. 3 (case 6).—Changes in blood pressure resulting from the intravenous administration of 5 mg. of regitine®; also from the intravenous administration of 0.05 mg. of histamine, and subsequent intravenous injection of 5 mg. regitine.®

The other two patients who had false positive reactions to intramuscular tests with regitine® had basal blood pressures that were low in the hypertensive range, and after the administration of regitine® the fall in blood pressure, though not of great magnitude, was enough to put them in the normotensive range. In one instance the blood pressure dropped from 164 mm. systolic and 100 diastolic to 130 mm. systolic and 78 diastolic. In the other case the fall was from 148 mm. systolic and 84 diastolic to 120 mm. systolic and 70 diastolic. A negative result of the histamine test in the latter and a negative result of the piperoxan test in the former ruled out pheochromocytoma.

RESULTS OF REGITINE® TESTS ON PATIENTS WITH PHEOCHROMOCYTOMA

Paroxysmal Hypertension.—Two patients with paroxysmal hypertension due to pheochromocytoma were observed. In the normotensive phase, regitine® had no unusual effect on the blood pressure whether given intravenously or intramuscularly. This was not unexpected. Regitine,® when given rapidly into the vein, did abort the attacks induced by histamine. Hightower, Priestley, and Roth [14] also have used regitine® to control the hypertensive crises of these patients at operation as originally suggested by Grimson.[9b,c]

Sustained Hypertension.—Five patients had sustained hypertension due to tumors of the adrenal medulla, which were removed surgically. The results of the pharmacologic tests in four of these cases are presented in figures 2, 3, 4, and 5.

Case 5.—A man, aged 47, had a right adrenal tumor that was removed, but hypertension persisted after operation because of functioning metastatic lesions. Preoperatively his resting blood pressure was 180 mm. systolic and 130 diastolic. A prompt and marked fall in blood pressure was observed after piperoxan was given intravenously and after 5 mg. of regitine® was given intramuscularly (fig. 2). Regitine® was not administered intravenously to this patient.

Case 6.—A pheochromocytoma, weighing 575 gm., was removed from the right adrenal gland of a woman, 46 years old, who had sustained hypertension in addition to a history of paroxysmal attacks of palpitation, tremor, sweating, and pain in the thorax. Before operation, 5 mg. of regitine® given intravenously promptly reduced her blood pressure from a basal value of 180 mm. systolic and 126 diastolic to 134 mm. systolic and 94 diastolic (fig. 3). Five milligrams of regitine® given rapidly intravenously quickly aborted an attack induced by histamine in this patient (fig. 3).

Two patients (cases 7 and 8) were sisters and were found to have bilateral pheochromocytomas at operation. Their case histories will be presented in detail in another paper.[15]

Case 7.—The younger of two sisters, aged 18, had a basal blood pressure of 190 mm. systolic and 140 diastolic. On two occasions regitine® given intramuscularly failed to reduce her blood pressure. But when regitine® was given intravenously, it produced a sharp, prompt fall in blood pressure followed by a marked rise. The reaction to the piperoxan test was likewise positive for pheochromocytoma (fig. 4).

Case 8.—The older of two sisters, aged 28, had extremely labile blood pressure that made the results of pharmacologic tests hard to interpret. Blood pressure fell promptly and markedly after the intravenous administration of both regitine® and piperoxan (fig. 5). Following the intramuscular administration of regitine,® blood pressure fell more gradually; the mag-

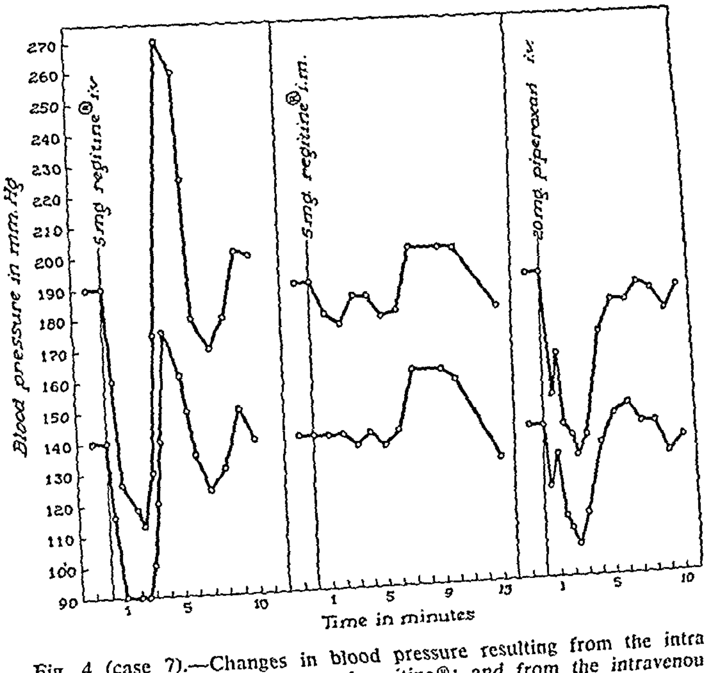

Fig. 4 (case 7).—Changes in blood pressure resulting from the intravenous administration of 5 mg. of regitine®; and from the intravenous administration of 20 mg. of piperoxan. The lack of immediate fall in blood pressure after intramuscular injection of regitine® should be noted.

[14] Hightower, N. C.; Priestley, J. T.; Roth, G. M., and Kvale, W. F.: The Control of Blood Pressure with Pheochromocytoma During Surgery and the Postoperative Period, unpublished data.

[15] Roth, G. M., and others: Bilateral Familial Pheochromocytoma: Report of Three Cases in the Same Family, to be published.

nitude of the fall was great when compared to the immediate preinjection level but not so great when compared to the lowest preinjection level.

Case 9.—The patient, a woman, 25 years old, had sustained hypertension secondary to pheochromocytoma. Preoperatively two tests using regitine® intravenously gave definitely positive results: the systolic blood pressure was reduced from 190 to 88 mm. and the diastolic from 130 to 62 mm. A test with piperoxan performed one hour before the second regitine® test gave negative results. A test with tetraethylammonium chloride also gave negative results. The pharmacologic diagnosis in this case, therefore, rested entirely on the positive result of the regitine® tests. At operation, four tumors were removed, three from the right adrenal gland and one from behind the liver just below the diaphragm above the usual site of the adrenal gland.

Thus regitine® was given intramuscularly to three of the five patients with sustained hypertension due to pheochromocytoma. Two of the four tests using regitine® intramuscularly on these three patients gave positive results and two gave negative results. For all four of the patients on whom the intravenous test with regitine® was done, results were positive. No false negative reactions were observed when regitine® was given intravenously.

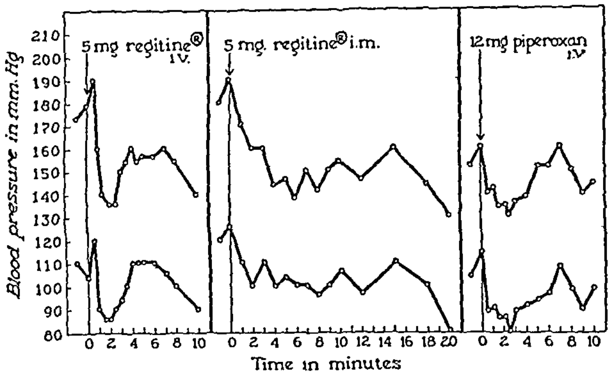

Fig. 5 (case 8).—Changes in blood pressure resulting from the intravenous administration of 5 mg. of regitine®; from the intramuscular administration of 5 mg. of regitine®; and from the intravenous administration of 12 mg. of piperoxan.

COMMENT

Pheochromocytoma associated with sustained hypertension can masquerade as and be clinically indistinguishable from essential hypertension; therefore, most patients with hypertension should have a test for pheochromocytoma. Regitine,® which has been found to be nontoxic, easy to administer, and free of unpleasant side-effects is an excellent drug for screening such patients. From the results just presented it is clear that regitine® should be administered intravenously rather than intramuscularly, since false negative reactions were encountered twice in cases in which pheochromocytoma was present when the drug was given intramuscularly.

Furthermore certain precautions must be considered in the execution and interpretation of this test. Regitine® is not a provocative test drug (such as histamine, tetraethylammonium, or methacholine) and is of no value in the diagnosis of paroxysmal hypertension owing to pheochromocytoma unless it is given during a paroxysm. In this respect it is similar to piperoxan and dibenamine.® As a test drug, regitine® should not be given in doses of more than 5 mg. In both instances in which 10 mg. were given, results were false positive. Emlet and co-workers also have found that 5 mg. is the optimal dose of regitine® for the test.[7a]

The importance of omitting sedation before any of the pharmacologic tests are performed for pheochromocytoma cannot be overemphasized. The patients should have no sedatives or narcotics for 24 hours before the test. In two patients to whom regitine® was given while they were heavily sedated, results were positive and led to a fruitless exploration. In one of these patients, regitine® tests performed without previous sedation gave negative results. The confusing results obtained when these drugs are administered to anesthetized patients[3] only serve to emphasize this necessary precaution. Likewise, patients who have hypertension and uremia are likely to have false positive reactions to regitine® tests.[7a] One such case is included in this report.

Furthermore, falsely positive results with regitine® are likely to be obtained in patients whose blood pressure is in the low hypertensive range (from 140 to 170 mm. systolic and 90 to 110 diastolic). Even a relatively small decrease may bring the blood pressure of these patients into the normotensive range and thus give the false impression of a positive reaction. It is preferable to use a provocative test, such as histamine, for these patients.

Before any of the test drugs are administered, the patient's blood pressure should be allowed to stabilize while he rests in a quiet environment. If the drugs are given too soon, the depressor effect of rest in bed alone may be attributed to the drug. Finally it must be realized that 66% of all patients to whom regitine® was given responded with a fall in blood pressure that averaged 20 mm. systolic and 14 diastolic. A fall in blood pressure of as much as 30 mm. systolic and 20 diastolic was frequently observed in patients with hypertension due to causes other than pheochromocytoma. In spite of all these precautions, hypertensive patients will be encountered occasionally in whom the depressor effect of regitine® will be great enough to simulate that in patients with pheochromocytoma. One such patient was encounterered in this series of 259.

As a screening test to rule out pheochromocytoma, regitine® is preferred to piperoxan because it is a pleasanter drug from the patient's standpoint and because it is almost free of the unpleasant side-reactions caused by piperoxan. Furthermore, regitine® is a safer drug to give to hypertensive patients because it does not produce the alarming rise in blood pressure that is frequently encountered after giving piperoxan.

Regitine® is easier to administer, as the test can be performed by one person, who can give the injection in an instant and then record the blood pressures. In contrast, piperoxan must be given more slowly and hence one person must give the injection while a second person records the blood pressures. For the unaided general practitioner the regitine® test is preferable.

No falsely negative reactions have been recorded as yet from regitine® given intravenously. The fact that false positive reactions occur with disappointing frequency does not detract from its value in a screening test. These false positive reactions can be kept at a minimum if all the precautions mentioned are observed. All positive reactions should be checked with piperoxan or one of the provocative tests. The surprising frequency of false negative results produced by piperoxan must be kept in mind.[6] This all points to the important fact that no single test is infallible in the diagnosis of these tumors.

SUMMARY AND CONCLUSIONS

Regitine® (C-7337) has been used as a test for pheochromocytoma on 259 patients, 7 of whom had pheochromocytoma. The test is most reliable if the drug is given intravenously in doses of 5 mg. When given in this manner, regitine® produced a marked fall in blood pressure in patients who had sustained hypertension secondary to pheochromocytoma. Regitine® had some depressor effect on the blood pressure of 66% of patients who had essential hypertension, but blood pressures of these patients were usually decreased less than 35 mm. of mercury systolic and 25 diastolic.

False positive reactions were obtained in 3 out of 149 patients without pheochromocytomas to whom regitine® was given intramuscularly and in 4 out of 107 patients to whom regitine® was given intravenously. These false positive reactions were attributed to the following factors: (1) sedation before the test, (2) uremia, (3) basal blood pressures that were in the low hypertensive range, and (4) the unexplained depressor effect of regitine® on the blood pressure of some hypertensive patients.

Regitine® is a safer and pleasanter test drug than piperoxan and also is easier to administer. It is an excellent drug to use for a "screening test" on all hypertensive patients to rule out pheochromocytoma. Equivocal reactions with regitine® should be confirmed by pharmacologic tests with other drugs, as no one drug is infallible; however, it must be emphasized that in one of the patients reported herein the preoperative diagnosis was made on the basis of the markedly positive result of the regitine® test and in spite of a negative result of the piperoxan test.

MESENTERIC VENOUS THROMBOSIS ASSOCIATED WITH ACUTE APPENDICITIS IN A YOUNG CHILD

RECOVERY FOLLOWING RESECTION OF INFARCTED INTESTINE

Edward M. Miller, M.D.
and
Robert Bryant, M.D., New York

Mesenteric vascular occlusion is one of the rarest and most uniformly fatal of the intra-abdominal catastrophes. Without surgical therapy, the condition carries an extremely grave prognosis. The recently reported mortality rates following definitive operative treatment vary between 60% and 70%.[1] McClenahan and Fisher,[1c] reviewing the literature up to 1948 and including their own series, were able to report a total of 616 cases of mesenteric vascular occlusion, in 43 (7%) of which the condition was treated successfully by intestinal resection.

Mesenteric vascular occlusion may be arterial or venous in origin. Arterial occlusion is most often associated with arteriosclerosis and cardiac disease. Mesenteric venous thrombosis is usually a complication of acute intra-abdominal infections, such as acute appendicitis, pelvic thrombophlebitis and abscess, and diverticulitis and peritonitis.[2]

The age range of greatest incidence of mesenteric vascular occlusion is between 20 and 70 years, with an average age of 43 years.[1a] The condition is decidedly rare in children. In 1940, Johnson,[3] including his own case, found only 11 cases of mesenteric vascular occlusion in infants and children in the English literature. In the case to be reported, mesenteric venous thrombosis associated with acute appendicitis occurred in a 2½-year-old child. Resection of the infarcted intestine with primary anastomosis resulted in complete recovery. Although instances of mesenteric vascular occlusion have been reported in infants of 1 month[4] and 4 months,[5] review of the literature does not reveal a case of successful intestinal resection for the condition in a child of this age group.

REPORT OF A CASE

On Oct. 12, 1951, a 2½-year-old Negro male child was admitted to the pediatric service of Flower and Fifth Avenue Hospitals with the complaints of sore throat and abdominal pain. The present illness began on the morning of the fifth day prior to admission, at which time the patient complained of a sore throat. His mother noted that he seemed ill, and she reported that his temperature was 102 F at that time. On the following day, the patient's throat pain was worse and he was taken to a local hospital, where the diagnosis of "acute tonsillitis" was made. He was given an injection of penicillin. On the third day of his illness, the patient's fever and sore throat persisted and he was given another penicillin injection. The day before his admission, the patient's temperature rose to 104 F, and, along with the sore throat, he began to complain of diffuse abdominal distress. He was listless and anorexic but did not vomit. His bowel movements were normal, the last one occurring on the day before admission. He was again given a penicillin injection at the clinic of his local hospital. The patient was seen at Flower and Fifth Avenue Hospitals for the first time on the afternoon of Oct. 12 and was immediately admitted to the pediatric ward. His complaints at the time of admission were essentially those of the preceding day: sore throat and diffuse abdominal pain, which was apparently not colicky.

The neonatal and postpartum courses were normal. There was no history of serious past illness. The child had received the usual immunizations and vaccinations.

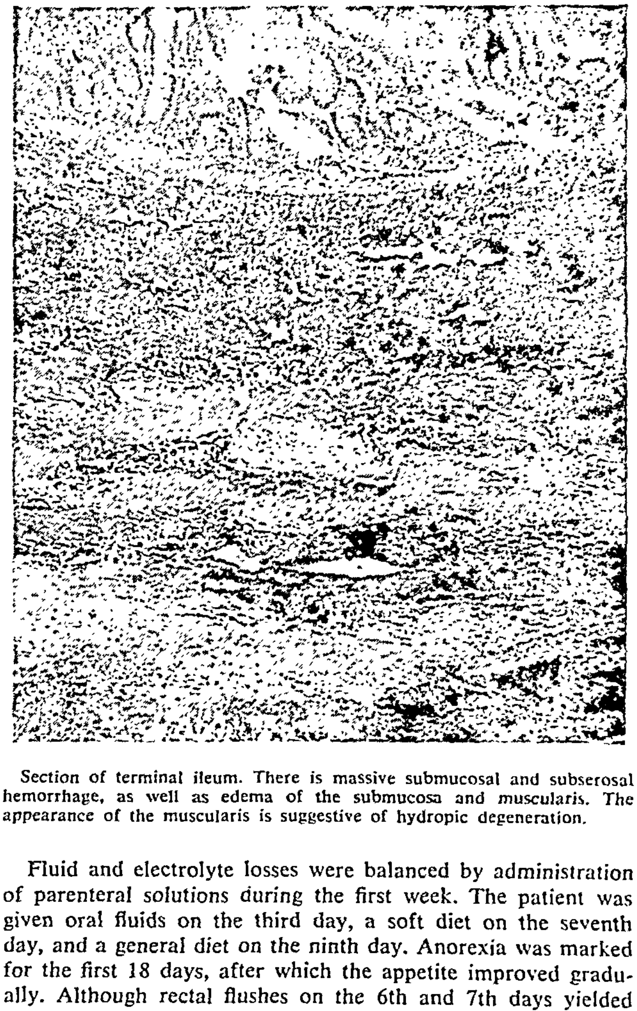
Physical examination revealed a well-developed and well-nourished young child. He was feverish and irritable and resisted examination. His weight was 30½ lb. (13.8 kg.). The temperature was 103.4 F rectally, the pulse rate 96, and respirations 30. The pharynx and tonsils were beefy red and edematous but without exudate. There was diffuse mild tenderness throughout the abdomen but no rigidity. Rectal examination was unsatisfactory but revealed no localized tenderness, mass, or blood.

Laboratory observations were as follows: hemoglobin 11.2 gm. (72%), erythrocytes 3,700,000 per cubic millimeter and leukocytes 18,500, with 81% polymorphonuclear neutrophils. Blood culture yielded no growth. The urine was normal except for a moderate number of hyaline and finely granular casts.

Late in the evening of the day of admission, surgical consultation was requested because the patient was becoming more toxic in appearance, and there had been a rapid increase in the severity of the abdominal pain. On examination at this time, there was extreme tenderness of the entire abdomen, although it was more marked in the right lower quadrant. There was voluntary spasm but no rigidity. The abdomen was not distended. Neither abdominal nor rectal examination revealed the presence of a mass. A flat roentgenogram of the abdomen showed a small amount of gas irregularly distributed throughout the colon. Several loops of small intestine were also slightly distended with gas in the middle and lower portions of the abdomen. Because of the severity and progression of the patient's abdominal signs, exploratory laparotomy was deemed advisable. Codeine, 1/8 grain (8 mg.), and atropine, 1/350 grain (0.17 mg.), were given as premedication.

The patient was anesthetized with cyclopropane, and a plastic cannula was inserted in an ankle vein. Palpation of the abdomen under anesthesia revealed the presence of a doughy elliptical mass, approximately 10 cm. by 4 cm. in size, lying horizontally in the right lower quadrant. The abdomen was entered through a low right rectus muscle-splitting incision. When the peritoneum was incised, a thick, purulent, fecal smelling, nonsanguineous fluid was encountered, and about 200 cc. was removed by suction. Several loops of normal appearing small intestine protruded through the incision. These were packed off to expose the affected bowel. The terminal ileum was edematous and reddish purple for a distance of approximately 17 cm. This segment of bowel was doughy and heavy, lying upon the posterior pelvic brim. The affected ileum was about 5 cm. in diameter but was not distended; the wall was thickened and soggy in texture. The purplish discoloration stopped abruptly at the ileocecal valve. However, the most marked change was observed in a 10-cm. segment just proximal to the ileocecal valve. In this area, the ileum was purplish black, thin-walled, and lusterless. There were several flecks of fibrin on the affected bowel, but no adhesions were noted. The cecum was edematous and red. The appendix, which was necrotic in its terminal third, was adherent to the under surface of the ileocecal mesentery. The mesentery to the terminal ileum and cecum was greatly edematous, its thickness approximating 2.5 cm. There were numerous enlarged pink friable lymph nodes throughout the mesentery. There had been no evidence of internal hernia or intussusception. Therefore, it was our belief that we were dealing with an ascending mesenteric venous thrombophlebitis that was probably secondary to the acute gangrenous appendicitis. The discolored ileum was wrapped in hot packs for 30 minutes, during which the appendix was extirpated. When the ileum was reexamined, its color had improved somewhat but was still bluish; pulsations and contractility were noted in all but the terminal 10 cm. The latter segment was plum-colored, thin-walled, and dull appearing; it did not exhibit peristalsis when stimulated and lacked arterial pulsations. Believing this segment to be nonviable, we elected to perform a resection and primary anastomosis. The distal 30 cm. of ileum, the cecum, and about 5 cm. of ascending colon were resected, well beyond the grossly affected area. The ileum was sectioned obliquely in order that its diameter might be equalized with that of the colon, and an end-to-end ileo-ascending colostomy was performed. A 22 F catheter was threaded through a Witzel enterostomy located about 2 ft. (61 cm.) proximal to the ileocolostomy. The tip of the catheter was placed at the anastomosis, while its opposite end was brought out through a stab wound in the left lower quadrant to provide decompression of the segment proximal to the anastomosis. Drainage of the right lumbar gutter and pelvis was effected by two Penrose drains extending through a stab wound in the right lower quadrant. The operating time was 2 hours 35 minutes, during which the patient's condition was considered good. A slow intravenous infusion of 250 cc. of isotonic sodium chloride solution was administered during the operative procedure.

The postoperative course was remarkably uneventful. Massive doses of antibiotics (including aureomycin, penicillin, and streptomycin) were administered parenterally for the first 10 days. At no time did the temperature rise above 101.8 F. (rectally); normal temperatures were recorded from the seventh postoperative day until discharge. Heparin was administered in 25-mg. doses every four to six hours for the first five postoperative days. Distention was notably absent. The enterostomy tube drained a daily average of 125 cc. of thick bilious fluid and was removed on the sixth postoperative day, with no further drainage.



Section of terminal ileum. There is massive submucosal and subserosal hemorrhage, as well as edema of the submucosa and muscularis. The appearance of the muscularis is suggestive of hydropic degeneration.

Fluid and electrolyte losses were balanced by administration of parenteral solutions during the first week. The patient was given oral fluids on the third day, a soft diet on the seventh day, and a general diet on the ninth day. Anorexia was marked for the first 18 days, after which the appetite improved gradually. Although rectal flushes on the 6th and 7th days yielded formed stools and flatus, it was not until the 14th day that the patient had a spontaneous bowel movement, followed by regular normal bowel action. Barium enema and gastrointestinal examination three weeks postoperatively demonstrated free passage of the medium through the anastomosis.

The patient's weight fell from a preoperative level of 30½ lb. (13.8 kg.) to 27¼ lb. (12.3 kg.) on the ninth day. At the time of dismissal from the hospital, on the 24th postoperative day, his weight was 29 lb. (13.2 kg.). The hemoglobin was 10.5 gm. (70%) on the day following operation; it rose to 12.5 gm. (80%), with 4,300,000 erythrocytes per cubic millimeter, at the time of discharge. The leukocyte and differential counts were normal at this time.

Pathological Observations.—Gross and microscopic examinations of the resected specimen were reported by Dr. F. D. Speer of the department of pathology as follows: The specimen consisted of 28 cm. of the terminal ileum and 8 cm. of the cecum and ascending colon. The ileum was markedly edematous and congested and dark blue. The mucosal and serosal surfaces were intact. The cecum was also markedly edematous throughout its wall but lacked the congestion present in the ileum. The mucosal surface was intact, but the serosal surface was sutured at the appendiceal stump. A small amount of mesentery was present in the region of the ileocecal valve, which contained many firm lymph nodes. The resected appendix measured 11 cm. in length and 0.7 cm. in diameter. Its serosa was hemorrhagically pigmented and covered by thick plastic exudate. On section, the lumen was distended and contained fecal matter and purulent hemorrhagic material. The wall was necrotic.

Study of sections of the appendix showed a large, partially calcified fecalith obstructing the lumen, with extensive necrosis of the mucosa and muscularis. Massive, purulent exudate and thrombosis of the vessels in the intermuscularis and serosa were noted. Study of sections of the terminal ileum showed massive edema and hemorrhage of the submucosa and muscularis (see the accompanying figure). Beginning necrosis of the muscle and inflammatory erosions of the muscosa were seen. There was also massive edema, hemorrhage, and purulent exudate in the serosa of the small bowel and fibrinous inflammation on the serosa.

The diagnoses were as follows: 1. In the appendix there was a large fecalith with extensive gangrenous inflammation and periappendicitis. 2. In the terminal ileum there was beginning hemorrhagic infarction with marked fibrinocellular enteritis and perienteritis. 3. The mesenteric lymph nodes showed nonspecific exudative and hyperplastic lymphadenitis.

COMMENT

Acute appendicitis in children less than 5 years of age carries a mortality rate that is more than three times that occurring in older children with the disease.[6] The greater mortality rate in the younger age groups is related to the high incidence of perforation with diffuse peritonitis. Taylor and Hodges[7] reported a 71.7% incidence of perforation in children less than 5 years of age with acute appendicitis. The frequency of perforation is in a large measure due to delay in definitive treatment. Difficulties in diagnosis, failure of parents as well as physicians to recognize that acute appendicitis does occur in the very young, the tendency to give cathartics for abdominal distress, and the lack of realization that appendicitis as well as gastroenteritis is frequently associated with respiratory infections in children all contribute to the delay that may allow perforation. Our case of mesenteric thrombosis illustrates to what extremes the complications of acute appendicitis and abdominal sepsis in children may ultimately progress. It further supports the view that immediate operation is the treatment of choice in young children with unrelenting abdominal distress and tenderness.

Treatment of an acute respiratory infection without consideration of associated abdominal distress may prove fatal. It should be emphasized that upper respiratory infections precede acute appendicitis in children in approximately 20% of cases.[8] Vigorous therapy of pharyngitis or tonsillitis with antibiotics may mask the symptoms of progression of smoldering appendicitis. Therefore, when antibiotics are being administered, one should maintain a high index of suspicion of appendicitis when confronted with vague abdominal complaints. It has been demonstrated that penicillin therapy may alter the coagulability of the blood[9]; this may have been an additional factor in the development of the mesenteric vascular thrombosis in the reported case.

Several points in the surgical management of mesenteric vascular occlusion as related to our case deserve mention. Palpation of the abdomen under anesthesia revealed the presence of a mass that was not noted in the previous physical examination. The position of the mass helped us in deciding on the location of the incision. Young children do not tolerate enterostomies well; for this reason, we elected to do a resection and primary anastomosis. This case illustrates the value of resecting well beyond the grossly affected bowel when dealing with mesenteric vascular occlusion as has been emphasized by others.[10] Because of the need for immediate effective decompression of the segment proximal to the anastomosis, a Witzel enterostomy was employed, with the catheter extending to the anastomosis. It was considered that this method would be preferable to long-tube intestinal intubation in order to preclude the delay involved in advancement of the double lumen tube. Finally, following the suggestion of d'Abreu and Humble,[11] we administered heparin postoperatively in an effort to prevent further thrombosis. It is difficult to assess the effectiveness of this measure in our case since the coagulation times were not within therapeutic ranges, although large doses of the drug were administered.

SUMMARY

A case of mesenteric venous thrombosis occurring in a 2½-year-old child is reported. It is believed that the condition was secondary to acute gangrenous appendicitis. Wide resection of the infarcted ileum with primary ileo ascending colostomy resulted in complete recovery. The frequency with which serious complications attend acute appendicitis in the very young emphasizes that immediate operation is mandatory when there is a suspicion of an "acute abdomen."

Artificial Respiration.—The restoration of breathing and of efficient blood circulation invariably is an emergency procedure. . . . One minute after cessation of breathing, if artificial respiration is given, the chances for survival are excellent, assuming of course, that the patient's heart and circulation are in good condition. After two minutes of asphyxia the chances for survival are less, but still excellent, but when five minutes have elapsed the chances for recovery are small—only about 25%. As more time passes, even though artificial respiration has been performed effectively at each of these stages, the chances for recovery grow less and less, and by the twelfth minute of asphyxia they are practically absent.—Cecil K. Drinker, M.D., Physiologic Principles of Resuscitation and Oxygen Therapy, *Postgraduate Medicine*, June, 1952.

PROPYLTHIOURACIL AND METHIMAZOLE THERAPY

COMPARATIVE EXPERIENCES

Glenn W. Irwin, M.D., Helen D. Van Vactor, M.D.
and
Max S. Norris, M.D., Indianapolis

It is the purpose of this paper to report the results of the use of methimazole ("tapazole") in 45 patients and propylthiouracil in 54 patients in the management of hyperthyroidism at the Indiana University Medical Center and the Indianapolis General Hospital. All these cases were followed by one or more of us. They were treated in the outpatient thyroid clinics unless the severity of toxicity or complications necessitated admission to the hospital.

The diagnosis of hyperthyroidism in these cases was based on the characteristic features of the history and the results of physical examination and the usual laboratory studies. In the majority of cases three basal metabolism tests were made prior to treatment. Radioactive iodine (I^{131}) uptake with excretion studies and protein-bound iodine determinations were also made in many cases. Generally the patients were seen every two weeks in thyroid clinics, but in some cases the visits were every four weeks. A white blood cell and differential count were done at each clinic visit, and in most instances a basal metabolism test was also performed.

DOSAGE

It was our experience that the original daily recommended dose of 75 to 150 mg. of propylthiouracil was inadequate. If the clinical degree of hyperthyroidism was moderate or severe, our policy has been to use 300 mg. for small goiters, 400 to 500 mg. for those of moderate size, and 600 to 800 mg. for large goiters, estimated to weigh 250 gm. or more. We have arbitrarily used 15 mg. of methimazole daily when the goiter was small, 30 to 45 mg. daily when the goiter was of moderate size, and 60 mg. daily when the gland was large. Propylthiouracil has been given in three equally divided doses during the day. We have stressed that the methimazole should be taken in equally divided doses every eight hours. Iodine was not used concomitantly except in the occasional patient with severe hyperthyroidism in the propylthiouracil series. In occasional cases of severe hyperthyroidism in which iodine had been given prior to the propylthiouracil therapy, the iodine therapy was continued. When patients were euthyroid, strong iodine (Lugol's) solution was given for two or three weeks prior to surgery. In most cases the antithyroid drug was continued until the time of operation.

COMPARISON OF CASES

Table 1 summarizes the clinical data for the patients receiving propylthiouracil and for those receiving methimazole. A greater percentage of patients had received either iodine or propylthiouracil prior to treatment, and the clinical classification of severe hyperthyroidism was relatively greater in the group receiving methimazole. Otherwise the two series were similar, except that the incidence of nodular goiter in the group treated with propylthiouracil was greater than that in the group treated with methimazole.

Table 2 summarizes the data concerning dosage and the time required before a euthyroid state was reached in the two groups of cases. The average daily dose of methimazole, 38.8 mg., was essentially one-tenth the average daily dose of propylthiouracil, 355.4 mg. For the 43 patients treated with propylthiouracil and followed to a euthyroid state, it required 3.2 days of treatment for each unit of elevation in the basal metabolic rate. In the 35 patients controlled with methimazole therapy, the time required was only 1.5 days per unit. In five patients to whom iodine was administered before propylthiouracil, both the daily dose of the drug and the time required to reach the euthyroid state were less than the average for the entire propylthiouracil group. However, in seven who received iodine prior to methimazole, both the dose and the time for control were increased above the average for that series. Previous propylthiouracil or thiouracil therapy caused a slight reduction in

the daily dose and the time before euthyroidism was reached in the group receiving propylthiouracil, while there was a significant increase in both values in the group receiving methimazole.

Table 3 summarizes the toxic effects of and the unsatisfactory responses to treatment with the two drugs. The incidence of significant toxic reactions was similar for both drugs. One of the important differences between the two drugs was the 16.6% incidence of a slow response to propylthiouracil therapy as against no instances of slow response to methimazole therapy. In addition, an analysis of all patients followed to the euthyroid state revealed that 15 patients receiving propylthiouracil required four months or longer to be controlled, whereas only three patients treated with methimazole required four months or longer for control.

UNSATISFACTORY RESPONSE TO PROPYLTHIOURACIL THERAPY: REPORT OF CASES

The main objection to the use of propylthiouracil was that some patients required an extended period of treatment with 500 to 800 mg. daily before symptoms were controlled, whereas others failed to reach a euthyroid state with this dose. Not many reports in the literature stress this finding.

Case 1.—A 31-year-old man with a diffuse goiter (estimated weight of 200 gm.) had a severe degree of hyperthyroidism. Both the goiter and the symptoms were of approximately two years' duration, and he had received strong iodine solution for two months prior to admission. He was given 600 mg. of propylthiouracil daily for 85 days, and then the amount was increased to 800 mg. daily for 258 days. Treatment with the iodine solution was not continued. At the end of this time there was still considerable hyperthyroidism and thyroidectomy seemed inadvisable. I^{131} was administered with satisfactory control.

Case 2.—A 55-year-old woman with a large nodular goiter and marked toxicity received an average daily dose of propylthiouracil of 388 mg. for 341 days. At the end of this period she still had severe hyperthyroidism. There had not been any previous iodine therapy, and initially she was given 500 mg. of propylthiouracil daily for 35 days. Because of rather severe leukopenia, the dose was reduced to 300 mg. daily for 172 days. Then the amount was gradually increased to 400 mg. for 45 days, then 500 mg. for 62 days, and, finally, 600 mg. for 27 days. She then received 60 mg. of methimazole for 182 days, at which time she was considered to be euthyroid, and a subtotal thyroidectomy was done. The surgical specimen weighed 350 gm.

Leukopenia (i. e., less than 4,000)	3	1
Unsatisfactory response to treatment	9 (16.6%)	0
Treatment discontinued	5 (9.3%)	

Case 3.—A 21-year-old man with a large diffuse goiter (estimated weight, 200 gm.) and severe hyperthyroidism presented the complication of rheumatic heart disease with mitral stenosis and congestive heart failure. He had been treated by his local physician with 300 mg. of propylthiouracil daily for four months and then with strong iodine solution alone for an additional three months prior to admission. We administered 600 mg. of propylthiouracil plus 30 drops of strong iodine solution daily for 103 days, without improvement. Then methimazole was given, and the hyperthyroidism was controlled after 126 days of treatment with an average daily dose of 45 mg.

Case 4.—A 73-year-old woman with a large nodular goiter (estimated weight, 250 gm.), severe hyperthyroidism of six months' duration, and congestive heart failure received 600 mg. of propylthiouracil daily for 120 days, with little improvement. There had been no previous iodine or antithyroid therapy. She made satisfactory progress when 60 mg. of methimazole was given daily.

Case 5.—A 50-year-old woman with a small recurrent diffuse goiter (estimated weight, 60 gm.) was admitted with extreme hyperthyroidism. She had received strong iodine solution for a few days prior to admission. Iodine was given intravenously after admission, and oral administration of strong iodine solution was continued. She received 300 mg. of propylthiouracil daily for eight days, then 450 mg. daily for 25 days, and, finally, 600 mg. daily for eight more days. There was slight improvement evident, but the patient was still critically ill, with fever, diarrhea, and congestive heart failure. All medication was discontinued, but the fever persisted. Radiation therapy was then given over the thyroid without improvement. I^{131} was given cautiously in small multiple doses and resulted in a satisfactory response.

Case 6.—A 72-year-old woman with a large nodular goiter and severe hyperthyroidism received 500 mg. of propylthiouracil daily for 405 days before the clinical and laboratory findings of control were obtained. There was no history of previous iodine therapy.

Case 7.—A 60-year-old woman with a small diffuse goiter had severe hyperthyroidism of about three months' duration. She had received strong iodine solution prior to antithyroid therapy. We administered 300 mg. of propylthiouracil daily for 225 days. The dose was then increased to 400 mg. daily for an additional 134 days before the euthyroid state was reached. Iodine was not used concomitantly with the antithyroid therapy. It was felt that this dosage was adequate since the gland was small. The surgical specimen, estimated to be 80% of the thyroid, weighed 28 gm.

CASE 8.—A 59-year-old woman with a nodular goiter (estimated weight, 200 gm.) required an average daily dosage of 450 mg. of propylthiouracil for 277 days before control was obtained. This patient had hypertensive heart disease with congestive heart failure, and the added problem of prolonged hyperthyroidism was unfortunate.

CASE 9.—A 42-year-old woman with a small nodular goiter required an average daily dose of 408 mg. of propylthiouracil for 212 days before reaching a euthyroid state. She had received strong iodine solution prior to antithyroid treatment, and the iodine therapy was stopped when the latter was instituted. The surgical specimen weighed only 40 gm.

In summary, there were nine cases of the 54 (16.6%) in which the response to propylthiouracil was not satisfactory. In five of these cases treatment with the drug was discontinued because of the slow response. In the remaining four a prolonged period of treatment was required before control was reached.

COMMENT

The potency of methimazole and relatively quick control of symptoms with its use have led to its popularity as an effective antithyroid drug. In reporting our series of cases in which methimazole was used, we have compared the results with those obtained in a similar group in which propylthiouracil was used as a method of testing the newer drug's efficacy. The propylthiouracil study extended over a period of four years, whereas the methimazole study covered 17 months. Although additional factors will become evident with longer use, several things are worthy of notice at this time. The value of an antithyroid compound is based on its ease of administration, rapid induction of control, and freedom from toxic reactions. The proved toxicity of former drugs has pressed the search for a more potent one,[1] with the hope that the rapidity of response would be increased and the toxicity decreased.

The dosage of methimazole required is about one-tenth that of propylthiouracil, as reported by Bartels and Sjogren,[2] Hallman and Bondy,[3] and Beierwaltes.[4] That the amount required for control of symptoms may be more than initially recommended [5] is indicated by our average daily dose of 38.8 mg. (table 2). The average time required for patients treated with methimazole to reach a euthyroid state was 85.6 days and for propylthiouracil it was 148.6 days (table 2). The rate of fall of the basal metabolic rate was about twice as rapid with methimazole as with propylthiouracil therapy. As a general rule the subjective improvement in the patient was prompt with methimazole treatment, a delay being seen in those patients with large nodular goiters and severe toxicity. Other recent reports concerning the use of methimazole include those of Taylor and co-workers,[6] who treated 23 patients; Kendrick and co-workers,[7] who treated 32 patients; and McGavack,[8] who treated more than 50 patients.

Propylthiouracil therapy has been unsatisfactory at times because of the extremely slow response of some patients to large doses. As did Bell and Mishtowt,[9] we encountered patients who had been treated inadequately. In these latter patients the administration of adequate doses under close supervision led to good results. The cases reported above indicate that our patients had received what are generally accepted as large doses of propylthiouracil over prolonged periods and failed to respond or responded slowly. The dose ranged from 400 to 800 mg. daily. In four of our patients (cases 6, 7, 8, and 9), the time of treatment ranged from 212 to 405 days before hyperthyroidism was controlled. Propylthiouracil therapy was discontinued in two patients (cases 1 and 2) after an average of 342 days. In the remaining three patients (cases 3, 4, and 5), the seriousness of the hyperthyroidism and the slowness of response to treatment prompted the discontinuation of propylthiouracil therapy and the institution of other therapy. It is interesting to speculate as to whether a daily dose of 1,000 mg. of propylthiouracil would have produced a satisfactory response in these cases and whether this amount would have increased the incidence of toxicity.

Our cases are too few to permit us to draw significant conclusions concerning the effect of previous iodine therapy on antithyroid drug action. In those patients who had received iodine prior to propylthiouracil therapy, the daily dose of the drug and the time required for them to reach the euthyroid state were less than the averages for the entire group treated with propylthiouracil (table 2). Five of the patients with unsatisfactory responses to propylthiouracil therapy had received iodine previously; iodine therapy was continued in two and discontinued in three patients. The data for the group treated with methimazole show that there was an increase in the dose requirement and the time interval for control in those who had received iodine before treatment (table 2), and in none of these cases was iodine therapy continued during the antithyroid therapy. In our experience, previous iodine therapy did not influence the effect of the antithyroid drug so much as did the size of the goiter and the degree of toxicity. A longer time was required to control severe hyperthyroidism in patients with large goiters in spite of large doses of antithyroid compounds.

Toxic reactions occurred in 9.3% of the group treated with propylthiouracil, cessation of treatment being necessary in 3.7% of the patients. In the group treated with the other drug the incidence of toxicity was 6.6%, treatment with the drug being stopped in 4.4% (table 3). This latter figure agrees with the rate of toxic reactions reported by Bartels and Sjorgen.[2] One case of serious agranulocytosis has been reported.[10] It is realized that a wider experience than ours is needed to permit one to determine the incidence of toxicity due to methimazole therapy. Hines[11] reported that he has now received reports on approximately 1,300 patients treated with methimazole. He found the total incidence of side-effects to be 4.6%, as compared with an over-all incidence of 2.7% in about 2,000 patients treated with propylthiouracil. The incidence of serious side-effects, such as agranulocytosis and fever, was almost the same in the group treated with methimazole as in the group treated with propylthiouracil, whereas the incidence of skin rash and urticaria was higher in the patients treated with methimazole. It is our opinion that methimazole, like other antithyroid drugs, should not be used without careful clinical observation.

SUMMARY AND CONCLUSIONS

1. Forty-five patients with hyperthyroidism were treated with methimazole ("tapazole"), and 54 were treated with propylthiouracil. Results in the two groups are compared.
2. In the group treated with propylthiouracil there was a significant incidence of unsatisfactory response.
3. Methimazole is about 10 times more potent than propylthiouracil, although the dose used was higher than that originally recommended.
4. The time required for control of symptoms with methimazole therapy was about 60% less than that required with propylthiouracil therapy.
5. The size of the goiter and the degree of toxicity are important factors in the amount of antithyroid drug required and the time necessary for control of symptoms.
6. The toxicity due to methimazole approximated that due to propylthiouracil.

EXSTROPHY OF BLADDER

OBSERVATIONS FROM EIGHTY CASES

Robert E. Gross, M.D.
and
Samuel L. Cresson, M.D., Boston

Exstrophy of the bladder is a rare but tragic anomaly. In 1947 Higgins[1] stated that the incidence of malformation was 1 in every 50,000 births. In his series of 41 patients, 33 were males and 8 were females. In our own material there were 62 males and 18 females. The therapeutic attack on this disease includes these objectives: (1) to cure the incontinence by producing a receptacle that can receive urine and discharge it at frequent intervals at the will of the patient, (2) to remove the sensitive everted bladder mucosa and to repair the abdominal wall defect, and (3) to correct deformities of the genitalia in both male and female by plastic procedures. It is not necessary to attempt to give bony union between the two sides of the pelvis, for over a period of years sufficient fibrous stabilization occurs to give the patient a satisfactory gait.

This communication is a study of the Boston Children's Hospital cases observed during the last 20 years. There have been 80 patients, of whom 54 were treated surgically. Portions of this material have been reported on previous occasions. The entire series is summarized here.

CLINICAL PICTURE

Exstrophy of the bladder is a regional anomaly. The urethra and bladder are open anteriorly, the latter showing as a midline bulging mass in the lower abdomen. Below the umbilicus there is a defect in the abdominal wall, muscles, and fascia through which the bladder protrudes forward. The exstrophied bladder changes in size as the intra-abdominal pressure varies when the child strains or cries. On the lower part of the everted mass of membrane one can see the two small elevated papillomatous projections from which urine comes in intermittent discharges from the ureteral orifices. The membrane tends to become raised up in cauliflower-like heaps around these lateral ends of the trigone. The exposed mucosa is very sensitive, and touching or rubbing any portion of it will make the child wince or cry out with pain and discomfort. This hypersensitivity gradually decreases over the course of several years as the transitional epithelium changes to a squamous form. This transformation tends to begin at the periphery of the bladder, becoming most prominent in the superior and lateral parts. The trigone and tissues immediately surrounding it show little of this change.

In the male there is usually a complete epispadias, with the verumontanum and the ejaculatory ducts widely exposed in the posterior portion of the open urethra. The penis has a flattened shape, is somewhat shortened, and has an upward curve. The scrotum is usually normal but in occasional cases is bifid. In the female there is a midline cleft of the vulva and clitoris. The urethra appears as a shortened groove or sulcus. In some cases the lower third of the vagina is open anteriorly, exposing the cervix. Children thus afflicted are constantly wet by the continuous extravasation of urine. The skin of the lower abdomen, groin, medial parts of the thighs, and buttocks tends to become irritated, macerated, or ulcer-

---

[1] Higgins, C. C.: Transplantation of the Ureters into the Rectosigmoid for Exstrophy of the Bladder: Review of 41 Cases, J. Urol. 57: 693, 1947.

ated, depending on the care the child has received. These miserable youngsters have about them a uriniferous odor that becomes more pronounced as they grow older.

There is usually no umbilical depression in the abdominal wall. This flattening of the navel area gives the abdomen a peculiar appearance. While the rectus muscle bellies are widely separated in their lower half, some degree of diastasis recti is usually found between the navel and the ensiform process. The fascia in the midline is widened and thickened above the exstrophied bladder. Lacking a central fusion, the two bodies of the pubic bone are widely separated. This separation has been said to be an invariable characteristic of exstrophy of the bladder, but this is not always true. Higgins[1] described a patient in whom the symphysis was intact and a normal penis was present. Since the wings of the ilia are spread, the hips are wider than normal. The symphysis is greatly widened or attenuated; therefore patients so affected have an unstable pelvis and a waddling gait. After reaching walking age, they also have a rather characteristic posture; that is, they bend forward in an effort to keep their clothes from rubbing against the sensitive bladder mucosa and the irritated skin of their groins and thighs.

Children born with exstrophy of the bladder may have associated anomalies, some of which are incompatible with life. In our series we have found the following malformations:

Inguinal hernia	16
Imperforate anus	6
Undescended testicle	7
Spina bifida	7
Omphalocele	5
Rectovesical fistula	3
Rectoperineal fistula	2
Meningocele and myelomeningocele	3
Double penis	2
Bicornate uterus	1
Syndactylism	1
Supernumerary finger	1
Ectopic kidney	1
Congenital heart disease	1
Umbilical hernia	1
Clubbed foot	1
Preauricular sinus	1
Deformity of left leg with bifid femur and absence of tibia	1

EMBRYOLOGY AND PATHOGENESIS

In 1901 Hart[2] summarized the work of Kolliker, Graf Spee, Lieberkuhn, Keibel, and others. Since then Von Geldern,[3] Bremer,[4] and others have reported their studies on the anomaly of exstrophy of the bladder and epispadias. Bremer feels that in the formation of the urinogenital organs the primitive plate (that is, either the so-called cloacal membrane or the primitive groove) is made up of ectoderm and entoderm and extends from the anus up to and including the lower border of the umbilical cord. Normally, mesodermal masses enter from the sides, meet in the midline between the two layers of the primitive plate, and supply the substance from which the anterior abdominal wall is formed. Bremer and others believe that, when the mesoderm fails to meet in the midline, the abdominal wall will be deficient and the primitive plate will persist as a very thin and weak membrane that splits or cleaves as the embryo grows, leaving the deformity known as exstrophy of the bladder.

Complete epispadias has been explained as a malformation of the genital tubercle that has been brought about by the failure of ingrowth of the mesodermal masses from above downward. Under these circumstances the genital tubercles join inferiorly along the ventral surface but do not join dorsally. This failure to coalesce on the dorsal surface leaves a small, flat, upward-curved penis, with the urethra exposed throughout its length. In those occasional instances of bladder exstrophy accompanied by a communication with the alimentary tract that opens in the exstrophied bladder,[5] the fistula is explained on the basis of either of two aberrations in development. Not only is there exstrophy, produced as described above, but in addition there has been a failure of growth of those mesenchymal masses that normally come in and divide the cloaca into a rectum behind and a urogenital sinus in front. In other words, there is a persistence of the cloacal duct.

TREATMENT

Much can be said regarding the historical developments in surgical therapy for exstrophy of the bladder. We shall not mention all the investigators who contributed to our surgical knowledge by proposing procedures that have since been discarded or by devising techniques that have now been accepted as a part of standard treatment but shall present here only the program that we feel is the best approach to the therapy of exstrophied bladder.

Young[6] has reported the cure of urinary *incontinence* by inversion of the exstrophied bladder and repair of the vesical sphincter muscle in several stages. Our attempts at this have been so disappointing that we have abandoned them in favor of transplantation of the ureters to the sigmoid, utilizing the rectosigmoid as a urinary reservoir. This attitude is now almost universally shared by workers in this field.

[5] Johnston, T. B.: Exstroversion of the Bladder Complicated by the Presence of Intestinal Openings on the Surface of the Exstroverted Area, J. Anat & Physiol. 48:84, 1913.

The age at which ureters should be transplanted to the bowel gives room for discussion and for honest difference of opinion. Higgins [1] and others have favored an early age for performing this operation, believing that the externally draining ureter commonly gives rise to ascending ureteral infection and kidney damage. This is in distinct contrast to our observations, which show that such ascending infection is exceedingly rare. Furthermore, transplanting ureters from the abdominal wall to the bacteria-laden bowel can hardly be regarded as a method of protecting a ureter from infection. While it is technically possible to establish ureterocolic anastomoses in babies, it is our present opinion that it is better to defer such surgery until an age at which the child has learned habits of bowel continence. It will then be easier for him to continue anal continence after the fluid material is turned into the bowel. Furthermore, our performance of anastomosis in older children has now become almost devoid of surgical complication, a statement that cannot always be made by those who perform these anastomoses in babies. For these reasons we defer transplantation until the patient is 3 or 4 years of age. Our results thereby have been so satisfactory that there is little desire to change this policy. With simple measures the child can be kept comfortable until this age for surgery.

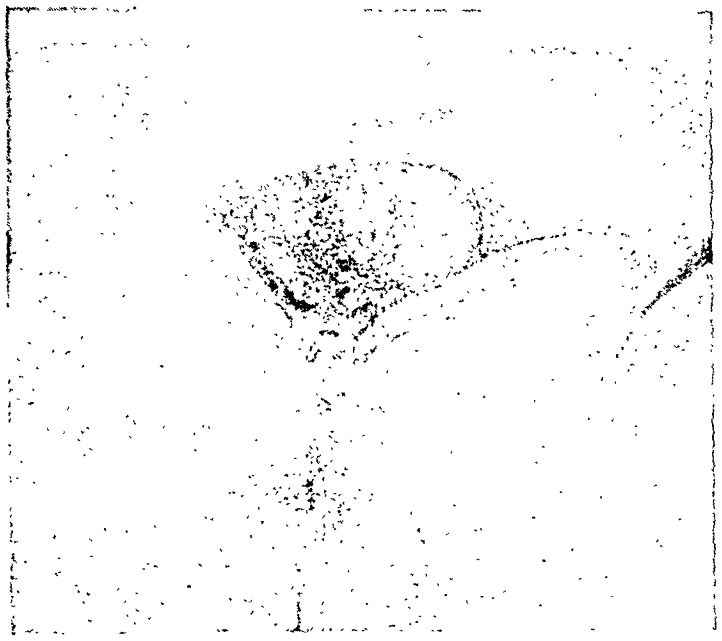

Fig. 2.—Exstrophy of bladder in 2-year-old girl. Note cleft condition of vulva, also bifid clitoris with vaginal orifice in full view. Squamous epithelium is replacing transitional epithelium on some of the exposed bladder surface.

Preoperative Care.—Babies and young children with exstrophy of the bladder can be managed so that they are reasonably comfortable and are not an undue burden on their parents. Frequently the family has been told by some physician that the bladder must be kept covered by a sterile gauze or dressing. This is a serious error, because it imposes a heavy financial burden in the maintenance of sterile coverings that are completely unnecessary. The exposed bladder tends to bleed if rubbed by any rough material such as an ordinary diaper, and it is also very painful if thus irritated. We have found it cheap, easy, and quite satisfactory to use clean (not sterilized) pieces of ordinary bedsheeting to cover the exposed bladder. The mother can keep on hand small bits of this material, 3 or 4 in. square. As one is to be used, it is smeared with petrolatum or boric acid ointment and put directly on the bladder area, and the diaper is then placed over this. (This fine-mesh material is better tolerated than surgical gauze.) When it is necessary to change the diaper, a new piece of the sheeting coated with petrolatum is placed again on the bladder. Little or no effort need be made to clean the bladder.

Surgical Considerations.—Before operation all of these children should be studied by intravenous (or retrograde) pyelography to visualize the ureters and pelves and to ascertain any anomalies that might have surgical significance. For two or three days prior to the transplantation of ureters, the bowel should be prepared by feeding the patient a low-residue diet and also by giving him at least two soapsuds enemas per day. We have little faith in the use of antibiotics or bactericidal drugs for reducing the bacterial flora of the colon, thereby presumably making operations on the colon safer. It is believed that a simple, well-performed anastomosis that does not leak is far more important than any quantity of drugs in reducing the incidence of postoperative regional or peritoneal infection. While it was formerly our custom to transplant the ureters in two stages, during the last 10 years we have usually transplanted both of them at the same operation, and in no instance have we regretted doing this.

Without describing here the details of operative technique of implanting ureters into the colon, it is well to set forth and emphasize certain principles we believe to be fundamental: (1) a transabdominal exposure; (2) simplification of technique; (3) establishment of a long intramural, submuscular implantation of the ureter; (4) projection into the lumen of the bowel of only a very short segment of ureter in order to minimize subsequent scarring and obstruction; (5) adequate anchorage of the ureter in its tunnel, so that it cannot withdraw and give leakage or obstruction; (6) leaving of a small urethral catheter in the ureter during establishment of the anastomosis, so that the tunnel cannot be made too tight; and (7) omission of inlying ureteral catheters after operation, so that the incidence of ureteritis is diminished. Pyelitis and pyelonephritis are seldom caused by ascending infection alone; they usually follow ureteric obstruction. It is therefore highly important to make sure the operation is carried out in such a way that there will be no subsequent delay in the flow of the urine.

Recently there has been considerable discussion regarding the tunnel-like type of anastomosis within the bowel wall versus an end-to-side union that permits an accurate mucosa-to-mucosa suture.[7] Our results with the

[6] Young, H. H.: Exstrophy of the Bladder: The First Case in Which a Normal Bladder and Urinary Control Have Been Obtained by Plastic Operations, Surg., Gynec. & Obst. 74: 729, 1942.

[7] Cordonnier, L. J.: Ureterosigmoid Anastomosis, J. Urol. 68: 276, 1950.

former method have been so satisfactory, provided it is performed in such a manner that no obstruction results, that we have seen no need to use the mucosa-to-mucosa union in routine cases. We have reserved the latter method for those rare instances in which the ureter is very large and is difficult to place in a colonic tunnel. When used in these circumstances, we have found the method quite satisfactory.

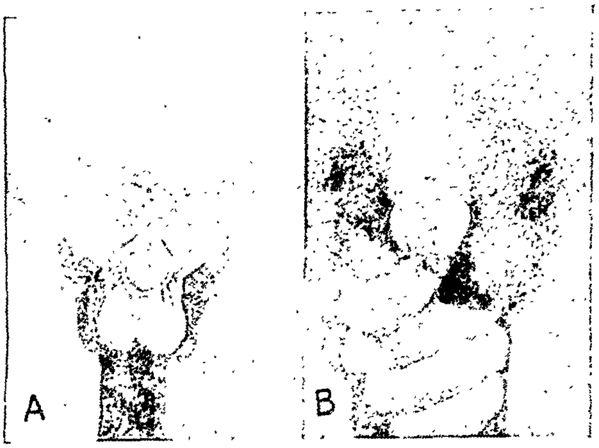

Fig. 5.—*A*, 8-year-old boy with exstrophy of the bladder, following transplantation of ureters into sigmoid, cystectomy, and repair of epispadias. *B*, same patient at age 17, with penis pulled down to show length and satisfactory appearance after plastic repair of epispadias.

While the exstrophied bladder can be removed at the time when ureters are transplanted, we prefer to leave this for a second operation some months later. Although the removal of a bladder is not difficult, in male patients the reconstruction of the penis is a meticulous and time-consuming job. If this is attempted at the time that the ureters are transplanted, there is too great a tendency to make haste and thereby give a poor reconstruction to the penis. We prefer to leave the removal of the bladder and the repair of the penis (or vulva) until a second operation, when there is more leisure to produce the best cosmetic repair of the genitalia. At the removal of the bladder and reconstruction of the penis or vulva, it is not necessary to remove all of the bladder tissue but only to excise the mucosa. The remaining wad of bladder musculature can be pushed inside the abdominal wall defect, and the rectus muscles and fasciae can then be suitably repaired. In the male a portion of the trigone is saved for the establishment of a small receptacle at the base of the urethra, which is then freed along its lateral edges and rolled in to the midline to make a tube (to transport semen). Over this tube the corpora and the portions of the glans are brought together from either side and are joined in a manner to bury the urethra. The skin is closed in the midline along the dorsum of the penis. This reconstruction, suggested more than 50 years ago by Cantwell and more recently emphasized by Young,[6] gives an excellent repair if the reconstruction is performed with delicacy and care. The penis so formed may be short, but it has erectile power and possesses a urethral tube running from the ejaculatory apparatus.

RESULTS OF TREATMENT

During the past 20 years we have observed 80 babies or children with exstrophy of the bladder, 54 of whom have been treated surgically. There have been no deaths, either at operation or at any time subsequent to hospital discharge. In the 54 children treated surgically, there were three cases of double bladders that were exstrophied and received no ureter. These bladders were excised. There were three patients in whom the exstrophied bladder was inverted and an attempt made to carry out the plan of Young's reconstruction. In one of these there was a fair result with respect to urinary continence; in the other two there was serious urinary incontinence, which subsequently led us to transplant the ureters into the rectosigmoid. In the remaining 48 patients there was no attempt to make a primary anatomic reconstruction of the bladder and urethra; the ureters were simply transplanted to the colon.

For the 50 patients with ureterocolonic transplants, 36 were done by two-stage procedures and 14 by one-stage bilateral ureterosigmoidostomies. In the early part of this series there were five instances of peritonitis. The affected children survived, but all have a nonfunctioning kidney on one side (in two, the kidney was subsequently removed). In addition there were six other patients with a nonfunctioning kidney that has caused no symptoms and has not been removed. We believe that most of these complications were due to the technical errors of establishing anastomoses that leaked or were too tight and led to ureteral obstruction. These convictions are strengthened by the fact that, as a result of greater attention to the operative principles above enumerated, there have been in the last 10 years no cases of peritonitis and only one of nonfunctioning kidney, and this has not had to be removed.

In the early part of this series there were many children in whom pyelitis developed postoperatively, making them extremely ill and difficult to treat. In the last decade such complications have become rare, a fact we attribute to the establishment of anastomoses that are free of obstruction and to the great effectiveness of antibiotics in aborting threatened attacks of pyelonephritis.

Rectal tolerance does not always develop at once but can usually be gained before the child is discharged from the hospital. Once tolerance to the presence of urine in the rectum is obtained, these patients can usually hold their urine and feces three to six hours during the day and need to get up only once at night. A child will still occasionally soil himself, however, especially when tired or emotionally upset. Proctitis has occasionally given us some concern in a patient. This is usually caused by acid

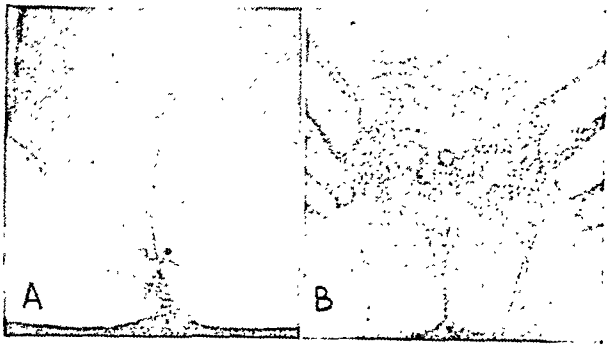

Fig. 6.—*A*, 7-year-old girl after bilateral ureteral transplants and cystectomy. *B*, same patient at age 13.

urine, and on alkalization by oral feeding of sodium bicarbonate the proctitis will generally subside rapidly.

A waddling gait is quite noticeable in the younger children. It is not unlike the gait associated with congenital dislocation of the hips. In older subjects the waddling can be controlled by the patient; in fact many parents have been able to teach their children to walk without any disturbance at all. In general, as these children get older, more stability of the pelvis is obtained, and the waddling is less apparent. No operative correction is necessary.

In our series postoperative pyelography has generally shown some degree of dilatation of the ureters and the calices of the kidneys for some months. It is now known that such dilatation is not necessarily permanent. The kidneys may not stabilize for two or three years, after which time some will return to normal while others will remain slightly dilated. In the last decade we have found that it is rare to find a progressive dilatation of the pelves and ureters. After the first six postoperative months, these patients should have intravenous pyelography two or three times a year for several years, or until stabilization of the urinary tract is observed. This is important in the handling of the case and in directing any additional therapy that might be required.

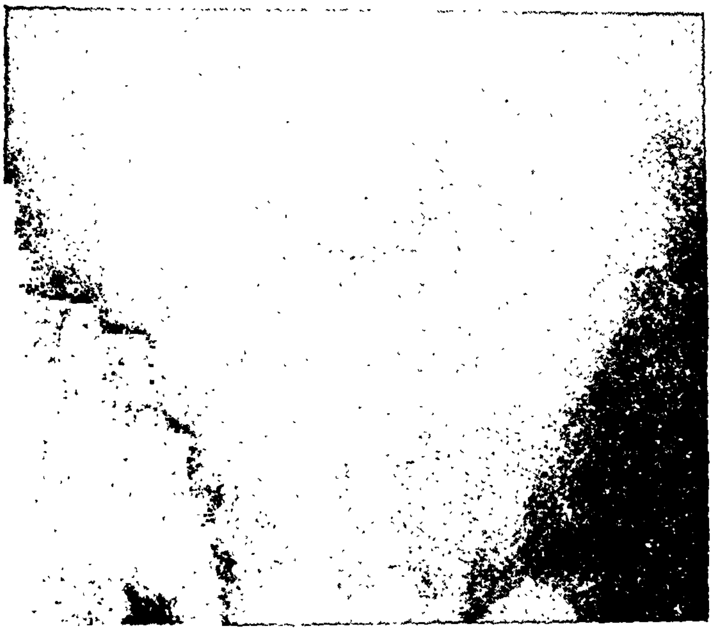

Fig. 9.—Intravenous pyelogram of 13-year-old girl, eight years after bilateral ureterosigmoidostomy. Patient has bilateral bifid renal pelves. There is excellent preservation of architecture of the pelves and calices.

Psychological problems in the female are not of great concern. If the operative steps are successful, the patient may be assured a relatively normal physiological and social life, and it will be possible for her to copulate and reproduce. In the male patient we are confronted with an entirely different disturbance, which is particularly troublesome during school years, when it is difficult for him to conceal the fact that he is different and must sit down to urinate. Parents and teachers who are cooperative and sympathetic can do much to ease this psychological tension. In our plastic repair of the epispadias we try to provide an adequate urethra and to reconstruct the penis so that the appendage is reasonably normal in appearance. After the plastic repair of the epispadias, the male patient should be assured that he can have a normal sexual life.

In 1950 Ferris and Odel [8] first reported blood electrolyte imbalance after the transference of ureters to the sigmoid. In a study of 141 patients who had undergone bilateral ureterosigmoidostomy for various conditions, it was found that various degrees of hyperchloremic acidosis and azotemia had developed in 79% of them. This evidence suggested that the change in electrolyte balance was due to absorption of the urinary solutes across the rectal mucosa from the urine stored in the sigmoid and rectum. The syndrome is manifested by fatigue, weakness, anorexia, loss of weight, salty taste, nausea, vomiting, nitrogen retention, polydipsia, and diarrhea. These symptoms are promptly relieved by correction of the acidosis.

Although Ferris and Odel [8] did not mention hypopotassemia as an accompanying factor, Diefenbach and his associates [9] reported a case with this added feature. In our 50 patients with ureteral transplants, we have recognized this syndrome in only one. It is our impression that such complications are much more likely to occur after ureteral transplantations in adults than in children.

SUMMARY

A report is made of 80 children born with exstrophy of the bladder, of whom 54 have been treated surgically. Some of the preoperative and postoperative problems and their treatment are presented. In the 50 patients treated by ureterosigmoidostomy, there have been no deaths. It was necessary to remove a kidney from two of these patients. It is urged that particular attention be given to providing the best cosmetic repair of the genitalia after the exstrophied urinary bladder has been removed. While there are many distressing features in treating this bladder and genital anomaly by employing the rectosigmoid as a urinary reservoir, the fact remains that the vast majority of the subjects can be given a comfortable existence and can assume a reasonably normal place in society.

Enlarged Cervical Lymph Node.—In the minds of many clinicians the removal of a cervical lymph node for diagnosis is a safe procedure with no more contraindications than laboratory examinations of the blood, spinal fluid, urine, feces, sternal marrow, etc., as the means of establishing the presence or the absence of a great variety of systemic disorders. In noncancerous diseases the procedures necessary to secure specimens for these various tests, including excision of a lymph node, are in themselves harmless and do not affect in any way the progress of the disease nor do they interfere with subsequent treatment. Should the disease be cancer, however, removal of a lymph node often is a serious and frequently an ultimately fatal handicap to overcome. Perhaps only the surgeon who treats cancer and follows his cases in sufficient numbers to determine end results will fully appreciate the serious consequences to the patient of the injudicious removal of a lymph node for diagnosis.—Hayes Martin, M.D., and Claude Romieu, M.D., The Diagnostic Significance of a "Lump in the Neck," *Postgraduate Medicine,* June, 1952.

CLINICAL NOTES

CHOLELITHIASIS AND PERFORATION OF THE GALLBLADDER IN AN INFANT, WITH RECOVERY

William H. Snyder Jr., M.D.
Lawrence Chaffin, M.D.
and
Leon Oettinger, M.D., Los Angeles

Cholecystitis with cholelithiasis is an unusual finding in infancy, but the condition has been reported several times in the literature of the last 200 years; however, it has always been an autopsy finding, and no case could be found that had been diagnosed during life and treated, with subsequent recovery, in an infant under 1 year of age.

REPORT OF A CASE

A 6-weeks-old female infant was admitted to the Los Angeles Childrens Hospital with a diagnosis of intestinal obstruction. At 2 weeks of age the baby began to be constipated. The scanty stools were described as white, yellow, green, and slimy. At 5 weeks of age, the abdomen began getting larger and became especially noticeable four days prior to admission. Bowel movements were now obtained only by enema. The appetite had been fair, but there had been intermittent vomiting for a week prior to admission. This vomitus contained only curdled milk.

On admission the baby appeared to be well developed, fairly well nourished, and acutely and chronically ill, with a markedly distended tight abdomen. The temperature was 100.6 F, and the blood pressure was 100/60 mm. Hg. Peristalsis was present but not remarkable. There was a suggestion of shifting dulness. The hemoglobin was 62% (colorimetric method), the white blood cell count 7,300, and the urine negative. A tentative diagnosis of abdominal malignancy with ascites was made and further studies were instituted.

Course.—Roentgenograms of the abdomen showed a moderately dilated small bowel with evidence of intraperitoneal fluid. A possible malrotation with chronic volvulus was considered, and a paracentesis was performed with removal of 400 cc. of yellow brown, slightly cloudy fluid. The possibility of a choledochus cyst was seriously considered. A barium enema revealed a normally placed cecum. Intravenous pyelograms were negative. The icteric index was 16, and cholesterol 118 mg. per 100 cc. of blood serum. A second tap allowed removal of 500 cc. of cloudy green fluid. The child took her formula quite well and vomited only occasionally. The temperature rose to 101 F, and on the sixth day after admission, surgery was performed. (Van den Bergh reactions were: direct, 2.3 mg. per 100 cc. of blood serum; indirect, 2.4 mg. per 100 cc.)

Surgery.—Under ether anesthesia, an upper abdominal right rectus incision was made. Blood was administered. Exploration revealed several hundred cubic centimeters of free bile-stained fluid between the coils of intestine. In some areas there were filmy adhesions with some pocketing. In the right upper quadrant was a perforated bile abscess cavity (fig. 2). The liver and loops of intestine had partly walled off this area. The liver itself appeared normal. At the base of the abscess was a perforation of the gallbladder at its junction with the cystic duct. The gallbladder contained one small stone, and there were numerous stones in the common duct. The duct was opened. A tiny probe could not be passed into the duodenum because of stones; some of these were washed out and an attempt made to pass a #8 catheter, but the duct was too small. A section of a #19 polythene® tubing was then inserted, which just fitted the lumen. Under syringe pressure the tiny stones were forced through into the duodenum, and the upper part of the duct was irrigated (fig. 2, inset). The polythene® tubing was inserted in the common duct for drainage. Penrose drains were put in place and the abdomen closed.

Postoperative Course.—Levine stomach tube section was instituted. Blood and fluids were administered intravenously; 300,000 units of penicillin and 150 mg. of terramycin were given daily. The child ran a febrile course for a few days. On the fifth postoperative day the polythene® tube was removed, since it was not draining properly. The Penrose drains were removed on the 10th day. The wound healed nicely with minor infection, and the child made an uneventful recovery. The slight jaundice cleared, and the stools have remained brown and normal. At the time of this report, three months after surgery, the child remains perfectly well.

Fig. 1.—The infant in case reported.

Additional studies showed that prothrombin activity was normal. Blood fragility of the baby, the mother, and the father were within normal limits. A cholecystogram of the mother showed good dye concentration and emptying.

COMMENT

The first reported case of gallstones in an infant was recorded by Lieutaud in 1767.[1] He found calculi in the gallbladder and ducts of a 25-day-old infant at autopsy. Since that time, about 90 cases have been mentioned in

---

From the Surgical Service, Los Angeles Childrens Hospital, and the University of Southern California, School of Medicine, Los Angeles.

[1] Lieutaud, J.: Historia anatomico-medica, Paris, 1767, quoted by Potter, A. H.: Biliary Disease in Young Subjects, Surg., Gynec. & Obst. 66: 604-610, 1938.

the world literature,[2] all either found or confirmed at autopsy. Two authors verify their presence even in the fetus.[3] Since Potter's report in 1938, only one additional case can be found in the literature.[4] The fact that no previously reported case has been successfully treated is due, in part at least, to its rarity. Since the presence of gallstones is not suspected in infants, the condition is overlooked in the differential diagnosis.

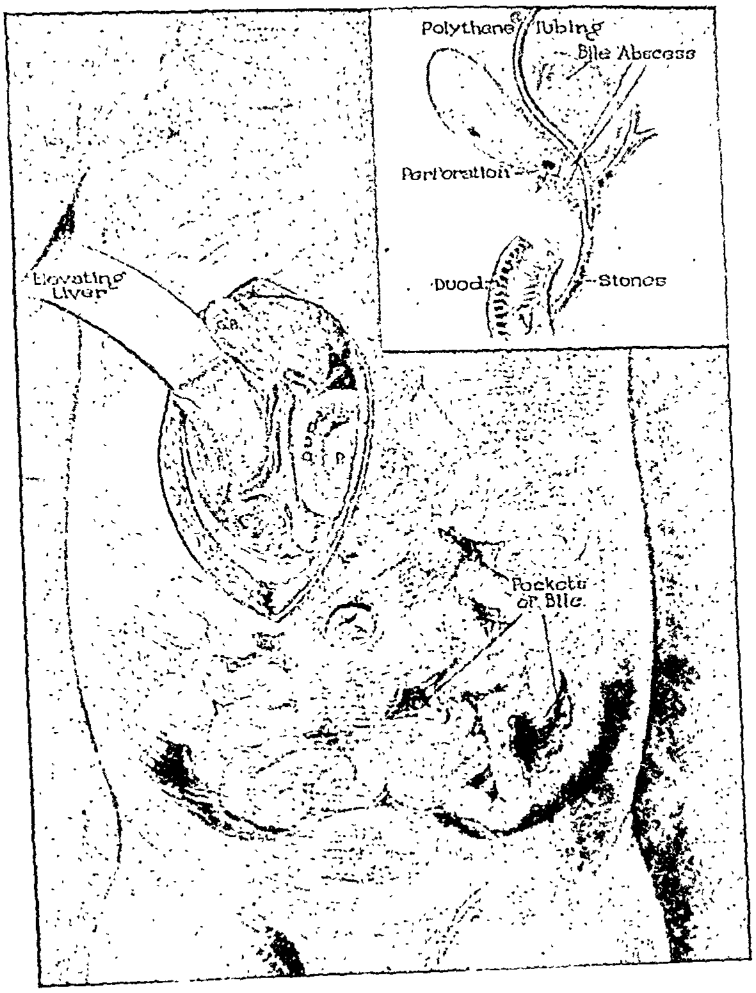

Fig. 2.—Drawing showing perforation of gallbladder at junction with cystic duct, stones in gallbladder and impacted in common duct, and bile abscess with perforation and generalized bile peritonitis.

Why it occurs is a matter of conjecture at the present time. The theories that have been advanced are not borne out by our case. Ladd and Gross [5] have suggested congenital hemolytic anemia as a basis for the formation of stones, but blood fragility tests of the baby, the father, and the mother were all within normal limits. Other conditions believed favorable to the formation of stones, such as biliary stasis, infection, and cholesterosis,[6] were apparently not present in our case. Kellogg [7] says "cholelithiasis in the newborn is due apparently to fetal pathology and is usually fatal."

The condition is known to occur in older children and young adults,[8] contrary to the classical concept of the disease as being one of middle and later life. There have been many reports of successful surgical treatment of gallbladder disease in this young group,[9] enough to emphasize the importance of considering it in a differential diagnosis, and of exploring for it when a laparotomy reveals no other demonstrable disease as a basis for the patient's symptoms. We wish to emphasize that it can also occur in infants and should be ruled out by surgical exploration, if necessary, in any infant with bizarre abdominal signs and symptoms.

There are other points, which this case brings out, that seem worth emphasizing. 1. Even though the true nature of the condition is not recognized preoperatively it can be successfully treated. 2. It provides a clinical illustration of the manifestations of common duct stones in infancy with final perforation of the gallbladder and bile peritonitis. In this case there was at first only constipation, then light colored stools, intermittent vomiting, and, finally, a distended abdomen with slight jaundice and bile-stained fluid, obtained on paracentesis. The course was gradual with increasing manifestations over a period of a month. There is evidence in this patient that bile was present in the free peritoneal cavity for a week before surgery. This seems to indicate that bile peritonitis without infection is well tolerated in the infant and even allows a nearly normal amount of peristalsis for many days. 3. It establishes a method of removal of stones within the infant's common duct by means of tightly fitting polythene® tubing accompanied by syringe pressure.

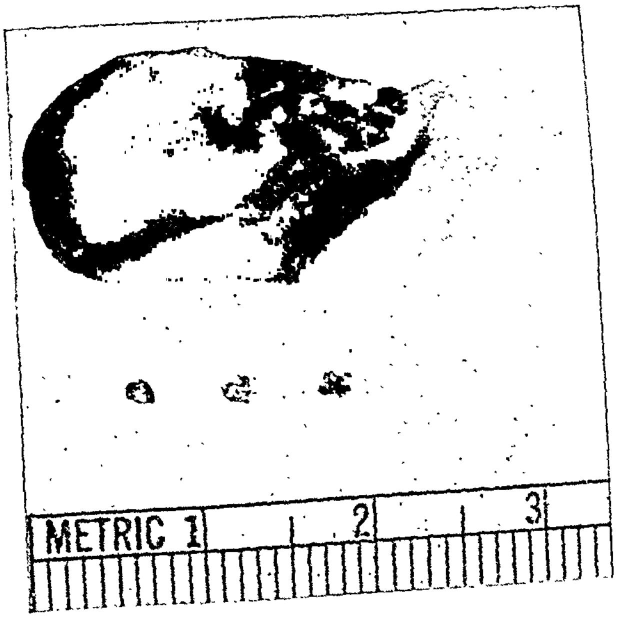

Fig. 3.—Specimens removed at operation.

SUMMARY

Cholelithiasis can occur in the infant and, if gallbladder disease is considered in the differential diagnosis, the condition can be successfully treated surgically. A method is suggested for the technique of removing common duct stones in the infant.

COMBINED INTERNAL AND EXTERNAL HERNIA WITH INCARCERATION OF BOWEL

Norman W. Thiessen, M.D.

and

F. Eugene Roach, M.D., Lakewood, Ohio

The following case is being reported for two reasons. 1. Incarceration of the bowel caused by a congenital defect in the appendicial mesentery has not been previously reported; the possibility of the existence of such a defect is not mentioned either in the textbooks on anatomy and embryology or in the articles written on mesenteric defects. 2. The simultaneous occurrence of an internal and an external hernia is so rare that it should be recorded.

In his original lectures on the anatomy of the intestinal canal and peritoneum in man, Sir Frederick Treves,[1] in 1885, described the occurrence of defects in the mesentery and stated that although they may occur anywhere in the intestinal mesentery, most of them are found in the mesentery of the terminal ileum. Cutler,[2] in 1925, collected data on 28 cases of intestinal obstruction caused by mesenteric defects, all of which occurred in the terminal ileum. Dolton and Robison,[3] in separate, recent articles, reviewed the literature on mesenteric defects. Iason [4] discussed various types of hernia in children in an article in his book devoted to hernia. In neither these reports nor in standard textbooks of anatomy is the occurrence of a defect in the mesentery of the appendix mentioned.

REPORT OF A CASE

The patient was a 1-month-old boy who had been delivered and had developed normally until two days before admission. Two testicles had been palpated in the scrotum, and an inguinal swelling had not been noted previously. For two days before admission, the baby appeared to have intermittent abdominal cramps, which the mother attributed to "colic." Fourteen hours before admission, the baby passed a hard, constipated stool, and an irreducible mass appeared in the right side of the scrotum. On examination, the baby did not appear acutely ill, so the attending physician decided to observe the infant temporarily. Twelve hours later, the mass was still irreducible, and the baby appeared listless. He had vomited twice during the night. His temperature was 98 F and his pulse was 110 per minute. Immediate surgery was advised and performed.

While the patient was under ether anesthesia, the inguinal canal was exposed through the usual right inguinal incision. The fascia of the external oblique was split in the direction of its fibers and the cremasteric fascia opened. The mass still could not be reduced. Because of inflammatory reaction, the wall of the hernial sac was identified with difficulty and opened. A long loop of terminal ileum was taken from the scrotum. The medial arm of this loop was dark red, and there were small areas of necrosis in the fat of the mesentery. In the upper portion of the sac, the appendix was found lying transversely and *pointing laterally.* The loop of ileum had herniated through a hole near the base of the mesentery of the appendix and, strangely enough, from the lateral to the medial side of the mesentery. The edges of the hole were smooth. It was necessary to sever the blood supply to the appendix to release the bowel. With the administration of hot packs, the color of the bowel returned to normal, and peristalsis became evident. There were no defects in the mesentery of this loop. The bowel was replaced in the abdomen and the appendix removed without inverting the stump. The hernial sac was dissected free, the base closed with a purse-string suture, and the excess sac excised. It was then found that a cystic mass was still present in the scrotum. The mass was brought out to the wound and found to be a hydrocele. A partial removal of the hydrocele sac was done and the testis replaced in the scrotum. The cremasteric fascia was closed and the cord dropped into place. The external oblique fascia was closed, leaving sufficient room at the lower angle for exit of the cord. The subcutaneous fascia and skin were closed with interrupted sutures. Cotton sutures, no. 40 and no. 60, were used throughout the operation. The postoperative course was uneventful, and the patient left the hospital on the seventh postoperative day.

Microscopic examination of the appendix showed extensive extravasation of erythrocytes, with slight to moderate necrosis. This involved particularly the mucosa and submucosa. In other sections the mucosa showed only moderate neutrophilic infiltration. The muscularsis and serosa in all sections showed slight to moderate infiltration with neutrophils as well as smaller numbers of eosinophils and lymphocytes. In addition there was considerable edema. The final pathological diagnosis was hemorrhagic necrosis and acute inflammation of the appendix.

SUMMARY

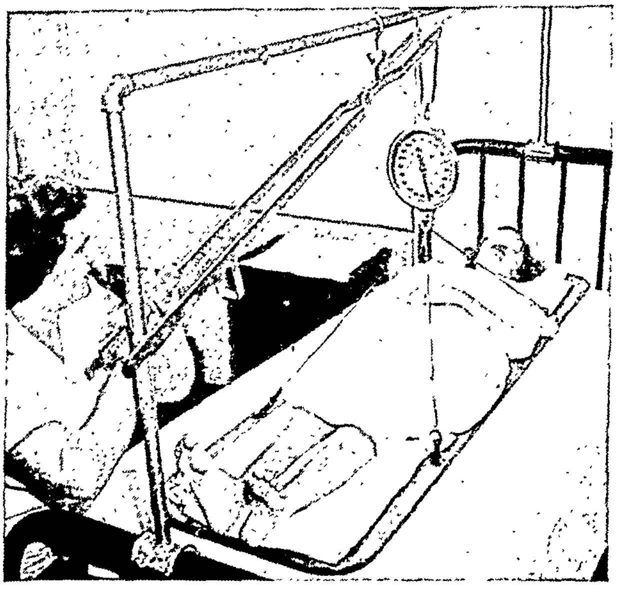
A case of a simultaneous internal and external hernia with incarceration of bowel through a congenital defect in the mesentery of the appendix is reported. As far as can be determined, this is the first instance of its kind to be reported.

14805 Detroit Ave. (Dr. Thiessen).

APPARATUS FOR WEIGHING BED PATIENTS

John V. Galgiani, M.D., San Francisco

In several departments of a general hospital it is necessary to weigh patients who are confined to bed. The difficulty of doing this by methods usually available has been felt especially in the medical service in cases in which frequent weighing is necessary to determine water retention or loss as well as changes in nutrition. The ap-



Patient being weighed, showing operation of apparatus described.

paratus illustrated in the figure was designed to fill this need. It was built in the maintenance shop of a hospital and required only materials readily available.

In use, the scales and lifting lever are hung over the patient's bed from any type of overhead frame. The lifting board, a 2 by 6 ft. sheet of ¾ in. plywood, is then slid under the patient, and the four lifting wires are attached to the corners of the board by snap hooks. The attendant raises the weighing apparatus by pulling down on the long lever arm, and when the patient is suspended an inch or two above the bed, reads the weight from the dial. The dial of the scale is adjusted to read zero when loaded with the board and lifting wires so that the patient's net weight is read directly. This apparatus has been found to be inexpensive, easily constructed, and accurate and safe in operation.

EXAMINATION OF HUMAN APPENDIXES FOR HISTOPLASMA CAPSULATUM

William M. Christopherson, M.D.
Madelyn P. Miller, B.S.
and
Emil Kotcher, Sc.D., Louisville

The reports of Raftery[1] and Raftery, Trafas, and McClure[2] indicate a high incidence, 12.3% in children 16 years and younger and 5% in an unselected series, of organisms identified morphologically by them as Histoplasma capsulatum in patients' appendixes. These reports stimulated us to analyze our own material critically, since we had not noted H. capsulatum in our routine histological examinations of either appendixes or mesenteric lymph nodes. It was of special interest to us since we were dealing with patients in a presumably endemic area where disseminated cases are being recognized with regularity and the diagnosis substantiated by both histological and cultural methods without apparent difficulty. At the same time there is a high incidence, about 60%, of positive reactions to the histoplasmin skin test (Armstrong,[3] Christie and Peterson,[4] and Palmer[5]) in subjects who have no clinical evidence of the disease.

MATERIALS AND METHODS

Routine surgical specimens from a public and a private general hospital and a children's hospital were submitted to our laboratory in a fresh state, immediately after removal. One hundred of these were examined by direct tissue smear prepared with Leishman's stain and cultured on Sabouraud's dextrose agar to which had been added penicillin and streptomycin (20 units and 40 units per cubic centimeter, respectively) in order to inhibit bacterial growth. These techniques have proved satisfactory for the demonstration of H. capsulatum in experimentally infected white mice.[6] Cultures were kept for one month before being discarded as negative. Routine histological sections from this same group were stained with hematoxylin and eosin. Twenty-four were acutely inflamed, and 76 showed no active inflammation. None revealed H. capsulatum by any of these techniques. (During this period an appendix from a patient with previously proved generalized histoplasmosis was obtained at autopsy and revealed the organism by culture, tissue smear, and section.)

In addition to the above series, 1,307 appendixes (512 of them with acute inflammation and 795 of them without active inflammation) were sectioned and stained with hematoxylin and eosin in the usual manner. The lymphoid tissue was then carefully searched for organisms. H. capsulatum could not be found in any appendix of this series. Small chromatin masses were occasionally found in the reticulum cells. These masses were interpreted as being phagocytized nuclear fragments. None of the fragments had structure suggestive of Histoplasma.

COMMENT

In the work reported by Raftery[1] and Raftery, Trafas, and McClure[2] the identification of H. capsulatum was made on a morphological basis on examination of tissue sections. In only one instance did Raftery[1] substantiate the morphological identification by culture in artificial mediums to show the characteristic tuberculate chlamydospores of H. capsulatum. In the second report,[2] although 2,135 surgical specimens were examined, complete study (microscopic examination of sectioned tissue, culture on artificial mediums, and animal inoculation) was performed in only 21 "current" cases. In only one of these cases were organisms found that resembled Histoplasma morphologically in sectioned tissue. Material from this appendix reproduced the disease in mice, although this apparently was not confirmed by cultural isolation of the organism. Material from the appendix was cultured at room temperature, but only a sterile mycelium was produced, which did not show the characteristic tuberculate chlamydospores. Similar findings were reported from a single case of mesenteric adenitis.

We have no explanation for our failure to duplicate the findings of Raftery[1] and Raftery, Trafas, and McClure.[2] We believe our criteria of histoplasmosis are more rigid, since they involve not only the finding of structures morphologically similar to H. capsulatum in sectioned tissues but also cultural isolation of the organism from such tissues. Conant and co-workers[7] have pointed out the desirability of such confirmatory procedures.

There is, of course, the possibility that subclinical histoplasmosis may exist in various forms in different geographic localities. Perhaps in this area (Kentucky and Southern Indiana) the healed or dormant pulmonary form is the only common one. We have not seen any data, however, to suggest this possibility.

From the Departments of Pathology and Microbiology, University of Louisville, School of Medicine.

This investigation was supported by the Medical Research Fund of the Commonwealth of Kentucky.

SUMMARY

One hundred appendixes (24 acutely inflamed and 76 "normal") were examined for Histoplasma capsulatum by culture on Sabouraud's dextrose agar, by tissue smears prepared with Leishman's stain and by histological sections stained with hematoxylin and eosin and found to be negative for this organism. An additional 1,307 appendixes (512 acutely inflamed and 795 "normal") were examined for structures morphologically similar to H. capsulatum by hematoxylin and eosin histological sections and found negative for this organism. One appendix obtained at autopsy from a previously proved case of disseminated, generalized histoplasmosis was found positive for H. capsulatum by culture, by stained tissue smear, and by hematoxylin and eosin histological sections.

PERIARTERITIS NODOSA

REPORT OF CASE WITH CHARACTERISTIC URINARY SEDIMENT

Leon R. Cole, M.D., Minneapolis

A type of urinary sediment believed to be characteristic of periarteritis nodosa and lupus erythematosus disseminatus was described by Krupp[1] in 1943. Only one report, that of Miale,[2] has appeared in the literature to confirm this observation. It is well recognized, of course, that hematuria is frequently present in periarteritis nodosa.

Krupp reported the presence in a single urine specimen of red blood cells, red cell casts, oval fat bodies, fatty and waxy casts, and, frequently, broad casts. There was also an abnormal amount of protein present. These findings were demonstrated in 14 of 21 cases of periarteritis nodosa and lupus erythematosus studied. The changes in the urinary sediment were found to vary with the state of the patient, being more extreme during clinical exacerbation and tending to disappear during remission. According to Krupp, red cell casts are the result of glomerulitis, and in acute glomerulonephritis they are the characteristic finding in the urinary sediment. Oval fat bodies and fatty and waxy casts reflect tubular degeneration and are the characteristic sediment of the nephrotic syndrome. Broad casts originate in the lower portions of collecting tubules, in which the flow of urine is slowed because the nephrons have had marked impairment of function. Broad casts are seen in renal failure, and in glomerulonephritis they are characteristic of the chronic stage. Addis[3] never observed the simultaneous presence of the above-mentioned types of urinary sediment in glomerulonephritis, though any two of the three types may be found at the same time. Hence Krupp considered this picture to be distinctive.

Krupp felt that he could correlate this urinary sediment qualitatively with the condition of the kidneys. Arkin[4] described four stages of activity of the lesions of periarteritis nodosa, ranging from acute inflammation to healing, and noted that all four may be present at the same time. Possibly the urinary sediment reflects this variable nature of the lesions.

The following case is reported in confirmation of Krupp's observation. The patient's clinical course was suggestive of periarteritis nodosa. Histological confirmation was lacking, however, as two muscle biopsies examined during life were reported as negative. The urinary sediment provided further evidence for the diagnosis.

REPORT OF A CASE

A. S., a 46-year-old woman, was admitted to University of Minnesota Hospital on Nov. 29, 1951, with a history of sore throat and cervical adenitis one month previously. Throat gargles were the only therapy, and symptoms disappeared in one week. Two weeks before admission puffiness of the face, feverishness, and occasional chilliness developed and persisted; for the last few days she had had dyspnea, orthopnea, and ankle edema.

Physical examination revealed an orthopneic woman with some periorbital and ankle edema. A few small tender lymph nodes were palpable at the angles of the mandibles. Ocular fundi were normal. Tonsils were enlarged. There was a right pleural effusion. The heart was slightly enlarged, and the blood pressure was 180/100 mm. Hg.

Urinalysis showed a specific gravity of 1.010, albumin of 2+, numerous red and white blood cells, red cell casts, oval fat bodies, fatty and waxy casts, and broad casts. Blood hemoglobin was 9.2 gm.; leukocyte count was 7,150 with 66% neutrophils, 31% lymphocytes, 1% monocytes, 1% eosinophils, and 1% basophils. Carbon dioxide combining power was 23 mEq., chlorides 114 mEq., and total serum protein 5.7 gm. per 100 gm. with 2.2 gm. albumin and 3.5 gm. globulin. Throat culture showed alpha and beta streptococci. Phenolsulfonphthalein excretion was 31% in 120 minutes. Quantitative 24 hour urinary protein was 13.5 gm. Chest film revealed slight cardiac enlargement, pulmonary congestion, and pleural effusion at the right base.

The patient was febrile during her entire hospital course. Her initial complaint was dyspnea, relieved somewhat by a thoracentesis. The leukocyte count was 14,650 on Dec. 4 and between 25,000 and 40,000 thereafter. Urinary output was good for the first 11 days, but the blood urea nitrogen level remained elevated. On Dec. 9 mild ascites and clinical signs of peritonitis developed. She received penicillin and aureomycin, but the occurrence of a generalized red macular skin rash caused the penicillin to be discontinued. Diagnostic paracentesis of the abdomen produced only a few milliliters of cloudy fluid, which contained many leukocytes with a differential count of 91% neutrophils, 7% mononuclears, and 2% eosinophils. The fluid was sterile. The evidence of peritonitis subsided somewhat. On Dec. 15 there was an onset of slight nuchal rigidity and flaccid weakness of most muscle groups of the right extremities. She was severely azotemic on Dec. 19 with a blood urea nitrogen level of 118 mg. per 100 cc. Treatment with the artificial kidney improved azotemia and acidosis; however, she was lethargic and had no clinical improvement. The blood urea nitrogen level rose again rapidly. She died from pulmonary edema on Dec. 26.

The autopsy was carried out by members of the department of pathology, University of Minnesota Hospital. There was cardiac hypertrophy with congestion of the lungs and liver. The right kidney weighed 270 gm. and the left 310 gm. Both kidneys were quite large, pale, and swollen, with numerous small subcapsular hemorrhages. The arterioles and medium sized arteries presented a similar over-all picture in most of the organs examined. These changes were most pronounced and variable in

the kidneys and were typical of periarteritis nodosa, mainly in the acute stage. Some of the glomerular capillaries showed similar changes. Some similar vascular changes were observed in the pulmonary septums. The brain was normal.

COMMENT

The antemortem diagnosis of periarteritis nodosa has been made in only a small proportion of the cases reported. Spiegel,[5] in 1936, noted that in only 12% of the cases in the literature had the antemortem diagnosis been made. This percentage has not increased, since Ward,[6] in a review of recent literature, found the diagnosis to have been made ante mortem in about 12% of instances. Millikan [7] states that periarteritis nodosa is disclosed by routine pathological examination in only 20 to 25% of biopsy specimens of patients ultimately proved to have the disease.

Involvement of the kidneys is frequent in periarteritis nodosa, as Baker [8] reported renal involvement in 80% of cases. All of Spiegel's 15 patients had renal lesions. Harris [9] reported involvement of the kidneys in 87% of 87 cases and the occurrence of uremia in 13%. Uremia developing in periarteritis nodosa, often described in the past, has been emphasized recently.[10] It would appear from the present case, considered in relation to the reports of Krupp and Miale, that the peculiar urinary sediment often encountered in this disease, although probably not pathognomonic, may be of considerable aid in diagnosis.

SUMMARY

A case of periarteritis nodosa is presented in which there was a type of urinary sediment described by Krupp[1] as being characteristic.

Preventive Medicine.—The most important concept of this century in the field of medical care is that preventive medicine is an integral and essential part of the everyday practice of medicine. It is not a separate body of knowledge to be understood only by a skilled technician who has been highly trained in this field. There is no "specialty" of preventive medicine as there is a specialty of surgery, radiology, or pediatrics. There is, of course, a specialty of public health, which is a well-organized body of knowledge and requires a high degree of skill. But preventive medicine must be interrelated with diagnosis, treatment, and rehabilitation. . . . The great physicians of all times have understood and have followed the principle that the practice of medicine is not simply an exercise in diagnostic acumen, nor a test of therapeutic skill, but requires a complete understanding of an individual as a person . . . who lives in an environment that has a profound influence . . . upon his health. They have also . . . followed the principle that he is entitled to the benefits of preventive medicine as an essential part of his medical care.—W. G. Smillie, M.D., Preventive Medicine and Public Health, ed. 2, New York, the Macmillan Company, 1952, p. 4.

ARTIFICIAL ELBOW FLEXION

George J. Boines, M.D., Wilmington, Del.

A mechanical device has been developed for artificial elbow flexion. It consists of a brace for the complete upper extremity, including the shoulder and the hand. The shoulder support is kept in place by means of a strap around the chest and under the opposite axilla. The hand mechanism, which appears fixed in the photograph, has been made movable at the wrist, so that the hand can be fixed in the pronated position or in the mid position by adjusting a screw at the wrist portion of the brace. The patient is able to flex the elbow at any desired position by swinging the arm forward. The elbow joint has several stops in flexion, with a release lever on the outside of the forearm. The hand may be turned into pronation or mid position by releasing screw catch at the wrist.

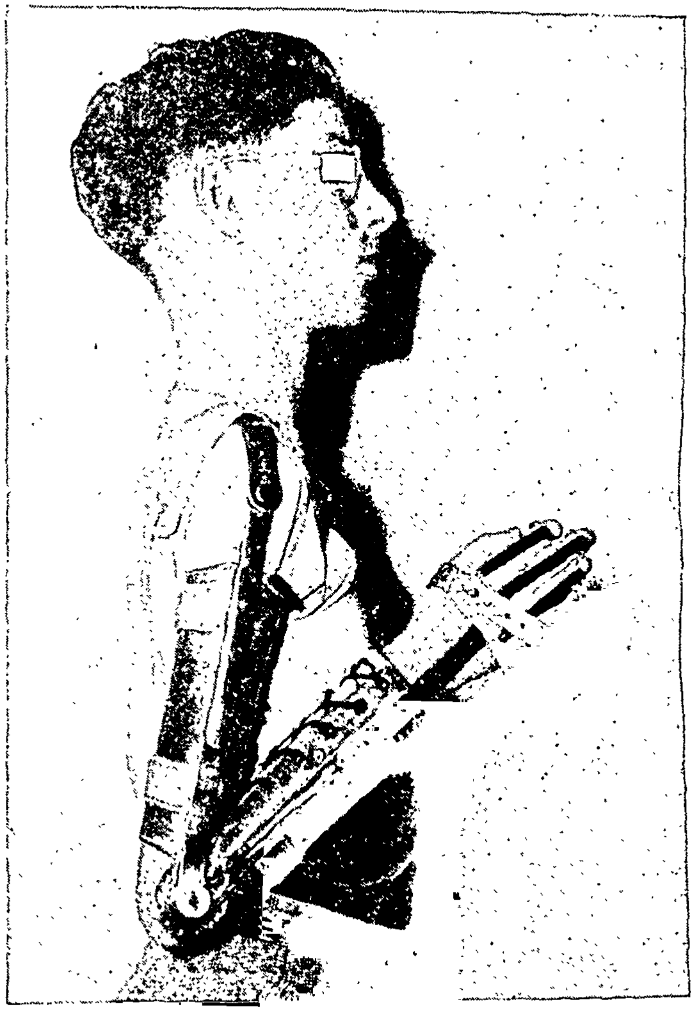

Fig. 2.—The right upper extremity is flail, with the exception of a trace of flexion power of the third and fourth fingers. The humerus is partly out of the socket. There is good power in the upper trapezius, rhomboids, supraspinatus, serratus anterior, latissimus dorsi, and levator scapulae. There is full range of motion of all joints.

The functional benefits of this device are as follows: 1. The flail extremity does not hang loose against the body. 2. Further subluxation of the head of the humerus is prevented. 3. When the patient is dressed and wearing a glove or has his hand in his trouser pocket, the disability is not apparent. 4. The patient is able to make

---

Several of the illustrations have been omitted due to lack of space; they will appear in the author's reprints.

The brace was developed through the cooperation of the General Limb and Brace Company, 1916 Market St., Wilmington, Del.

Attending chief of communicable diseases, including poliomyelitis, Doris Memorial Unit of Wilmington General Hospital and St. Francis Hospital.

practical use of the arm adduction power against his body and thus hold objects. He cannot do this without the brace. 5. In school and at home when working on a flat top desk, he is able to hold paper and turn pages of a book by using a pushing motion in which power is transmitted from the shoulder and scapula muscles. He could not do this without the brace. 6. The patient is able to push and move objects with the hand by the transmission of power through the brace from his shoulder muscles.

Improvements desired include automatic methods of releasing the elbow joint latch and of flexing the forearm. The device is being modified to permit artificial flexion and extension (by means of a spring) at the elbow for the ambulatory patient with a flail upper extremity.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

REPORT OF THE COUNCIL

The Council on Physical Medicine and Rehabilitation has authorized publication of the following report.

Ralph E. De Forest, M.D., *Secretary.*

ABSTRACT OF THE MINUTES OF THE ANNUAL MEETING

The Council on Physical Medicine and Rehabilitation held its Annual Meeting at the American Medical Association Headquarters in Chicago, on Dec. 14 and 15, 1951. The following Council members were present: Drs. Frank H. Krusen, Frank R. Ober, Morris A. Bowie, Anthony C. Cipollaro, Otto Glasser, Dean M. Lierle, George M. Piersol, Derrick Vail, Shields Warren, Arthur L. Watkins, and Walter J. Zeiter.

Dr. Krusen was reelected Chairman and Dr. Ober was reelected Vice-Chairman. In the field of education, it was reported that 72 questionnaires entitled "Teaching Program in Physical Medicine" were mailed to the deans of medical schools and 70 replies were received. As a result of this, a report was prepared entitled "Teaching Physical Medicine and Rehabilitation in the Medical Schools of the United States." It was planned to publish the article in The Journal. The activities of the Council's Advisory Committee on Education in relation to the development of the essentials for training schools for ancillary personnel in the field of physical medicine and rehabilitation was reviewed. It was voted that the Advisory Committee continue its work in considering a set of standards for such schools. The question of adequate training for those persons who do electrolysis was discussed. It was voted that the Secretary send a questionnaire to various schools of physical therapy and departments of dermatology in order to determine whether they would be interested in teaching persons to remove superfluous hair, thereby assuring training under the guidance of qualified medical personnel.

The activities of the Joint Committee on Rehabilitation formed by representatives of the Council on Physical Medicine and Rehabilitation and representatives of the Council on Industrial Health were discussed. The potential hazard inherent in the use of x-ray apparatus for the fitting of shoes was reviewed, as well as the activities of the Joint Committee in reviewing legislation regarding physical medicine and rehabilitation.

In a report regarding the dangers of radioactive isotopes, it was pointed out that the Atomic Energy Commission has been teaching persons how to handle them and that so far serious hazards have been avoided.

The activities of the Council and its Advisory Committee on Audiometers and Hearing Aids were reviewed. The need for reconsidering a standard procedure for evaluating the percentage loss of hearing and the problem of noise and health were considered.

The Council's cooperation with the Armed Forces, National Research Council, The American National Red Cross, and others in developing a new method of applying manual artificial respiration, the back pressure-arm lift method, it was reported resulted in the adoption of this method of manual artificial respiration by the previously mentioned organizations, as well as by this Council.

APPARATUS ACCEPTED

The following additional products have been accepted as conforming to the rules of the Council on Physical Medicine and Rehabilitation of the American Medical Association for inclusion in Apparatus Accepted. A copy of the rules on which the Council bases its action will be sent on application.

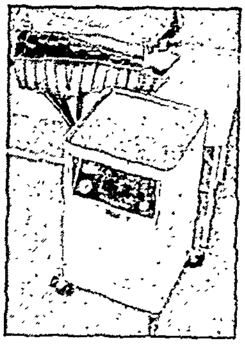
Ralph E. De Forest, M.D., *Secretary.*

Vaso-Pneumatic

Poor & Logan Manufacturing Company, 7319 Varna Ave., North Hollywood, Cal.

The Vaso-Pneumatic is an apparatus designed for use in the treatment of peripheral vascular disease. It consists essentially of two parts: one, a series of cuffs to be applied to the affected extremity of the patient; the other, a control cabinet which governs the distribution of pressure to the cuffs. Powered by an electric motor, the apparatus within the cabinet inflates and deflates the cuffs seriatim in such a way as to mimic a peristaltic wave passing in either the distal or the proximal direction.

Unpacked, the control cabinet measures 84 (height) by 48 by 48 cm. (33 by 18 by 18 in.) and weighs 59 kg. (130 lb.). Packed for shipment it measures 94 by 58 by 58 cm. (37 by 23 by 23 in.). A cradle for housing the rubber cuffs and supporting the patient's extremity is included in a separate carton which measures 15 by 23 by 71 cm. (6 by 13 by 28 in.). The combined shipping weights are 84 kg. (185 lb.).



Vaso-Pneumatic

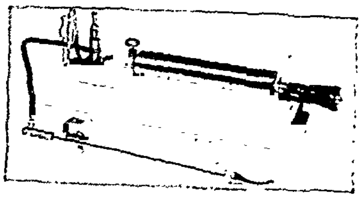
The motor requires a 60-cycle alternating current at 115 volts and draws 300 watts.

From acceptable sources the Council secured evidence which indicated that this apparatus was well designed and was useful in the treatment of certain types of peripheral vascular disease.

Gynogauge (Weisman)

Goodman-Kleiner Co., Inc., 5 E. 17th St., New York 3.

The Gynogauge (Weisman) is a modification of two forms of apparatus, the Gynographs, Models 1 and 2, previously accepted by the Council. It is a device for injecting carbon dioxide at controlled pressure into the uterine tubes. It comes in a carrying case that weighs, with contents, 2.8 kg. (6.2 lb.) and measures 40 (length) by 14.5 by 11.7 cm. (15¾ by 5¾ by 4⅞ in.).



Gynogauge (Weisman)

The Council obtained evidence which indicated that the apparatus was well made and performed satisfactorily under standard office conditions.

A NEW LONG-ACTING ESTROGEN

The discovery that the synthetic compound diethylstilbestrol possessed high estrogenic activity when administered orally prompted a search for related compounds with a more prolonged activity. In 1942, Robson and his associates [1] reported that the triphenyl ethylene derivative diethoxy-triphenyl bromoethylene (*αα*-di [-*p*-ethoxyphenyl] *β*-phenyl bromoethylene), or D. B. E., showed a markedly prolonged estrogenic action in mice subjected to ovariectomy when given in doses somewhat greater than those producing a threshold response. The English investigators showed this prolonged effect was due to the fact that, on introduction into the body, D. B. E. in contrast to the estrogenic substances then available was not immediately destroyed or excreted in the urine but was stored in a number of tissues, particularly the fat, and was only gradually eliminated from the body.[2] It was further shown that this compound was a proestrogen, a term introduced by Emmens to describe compounds that do not act directly on the vagina but must be absorbed into the body and metabolized to a true estrogen before inducing their effects.[3] Preliminary clinical trials indicated that menopausal symptoms could be controlled with weekly maintenance doses of the drug following an initial large priming dose. Since results with carcinoma of the prostate were less encouraging, it was suggested that either the dosage employed was too low or the body was unable to convert proestrogen to estrogen at a rate sufficient to provide an effective concentration for controlling carcinoma of the prostate.[4]

In this country, Thompson and Werner have studied another triphenyl ethylene derivative, tri-*p*-anisylchloroethylene, or TACE.[5] They have shown that this compound, like D. B. E., is initially stored in body fat and is slowly liberated and metabolized, probably largely in the liver, to a much more potent estrogen than the parent substance. In addition they noted certain differences between the effect elicited by TACE and by the estrogen hexestrol when given to mice in doses of equal biologic potency, as judged by uterine and vaginal changes. Thus TACE, unlike hexestrol, did not cause enlargement of the pituitary gland. Furthermore, TACE caused only a slight increase, while hexestrol caused a marked increase, in the weight of the adrenals, and TACE resulted in less ovarian atrophy than hexestrol. While these findings suggest fundamental differences in activity between the two estrogens, further work will be required before this interesting possibility is established, for, as the authors acknowledge, it is difficult to define strictly comparable physiological doses between two compounds with such widely different durations of action. Preliminary clinical studies indicate that TACE is as effective as diethylstilbestrol in the palliative treatment of carcinoma of the prostate.[6] It has been suggested that adrenal hypertrophy may be one of the factors limiting the value of estrogen treatment of prostatic carcinoma. If this is indeed the case and if it can be proved that TACE controls prostatic carcinoma without affecting the adrenals, this drug might offer advantages over estrogens now in use.

REGISTRATION OF MEDICAL GRADUATES

The National Advisory Committee to the Selective Service System has issued an urgent appeal to all 1951 and 1952 graduates of medical schools who have not already done so to immediately register with their local Selective Service System boards under the provision of Public Law 779. Previous registration under the general selective service law, the committee warns, does not exempt male physicians under the age of 50 from registration under Public Law 779, nor does the fact that a physician is deferred as a regular registrant. The only male physicians who are not liable for registration under Public Law 779 are those who are currently members of reserve components of the Army, Navy, and Air Force. Previous military service does not exempt physicians from such registration unless they are currently members of reserve components of the armed forces.

Preliminary study of the 1952-1953 survey questionnaire of interns, residents, and fellows in hospitals, being conducted by the Health Resources Advisory Committee of the Office of Defense Mobilization, indicates that there is a considerable number of interns, residents, and fellows who are not members of reserve components who have not registered under Public Law 779.

[6] Smith, P. G.; Rush, T. W., and Evans, A. T.: Preliminary Report on the Clinical Use of TACE (Chlorotrianisene) in Treatment of Prostatic Carcinoma, J. Urol. **65**: 886, 1951. O'Conor, V. J., and Sokol, J. K.: Evaluation of TACE as a Therapeutic Agent in Prostatic Carcinoma, Quart. Bull. Northwestern Univ. M. School **26**: 161, 1952.

The National Advisory Committee is also asking its state advisory committees to check with state boards of medical examiners to obtain the lists of all physicians granted licenses within the past two years. These will then be checked against Selective Service Public Law 779 registration lists to discover those physicians who are not registered in accordance with the law.

In issuing its statement, the National Advisory Committee called attention to the fact that failure to register as a special registrant makes such delinquents subject to investigation by the Federal Bureau of Investigation and liable to prosecution by the Department of Justice. It also pointed out that it believed that failure to register on the part of many 1951 and 1952 graduates has resulted from lack of understanding that they were required to register under both the general Selective Service System law and Public Law 779. Such failure the committee stated, however, is a specific violation of the Selective Service law.

HOUSE FLY RESISTANCE TO CHEMICALS

House fly resistance to DDT was first recognized in Europe shortly after the conclusion of World War II. Reports of house fly resistance to DDT in the United States were quite prevalent by 1947; by 1948 an alarming degree of DDT resistance was observed in California, and similar conditions were described by numerous investigators at scattered locations throughout the southern, eastern, and central United States. According to Decker and Bruce,[1] DDT and related materials such as methoxychlor are currently of little or no practical value in fly control in Illinois. With approximately 50% of the farms in the state harboring flies that are resistant to lindane and dieldrin, there is reason to believe that most if not all of the chlorinated hydrocarbon insecticides will have lost their usefulness within a year or two. In some sections of the United States where chlorinated hydrocarbons have been employed more extensively than in Illinois, conditions may be even worse.

In a previous communication,[2] the authors demonstrated that the initial processes of segregation and selection leading to establishment of high levels of resistance proceed slowly at first, but that, when resistance is once established, its intensification is rapid and proceeds to equilibrium with the toxicant found in the house fly's environment.

It has also been shown that contamination of breeding mediums contributes to development of DDT resistance under conditions prevailing in the field. DDT resistance appeared first and was intensified most rapidly on farms where sanitation was poor and where spraying operations resulted in serious contamination of manure and similar breeding mediums. Acquisition of tolerance for one chemical may predispose a strain of house flies to rapid development of resistance to some other chemical. In acquiring a high degree of resistance to DDT, flies also acquire a fair degree of resistance to methoxychlor but only a slight degree of resistance to lindane, chlordane, and dieldrin. These products apparently are closely related, and house flies resistant to any one of the three have a fair degree of resistance to the other two.

It seems possible, if not probable, that tolerance for insecticides may be extremely variable and may be induced by the independent or joint action of many factors. In some cases resistance is due to the house fly's ability to metabolize almost immediately or at least to decompose DDT into harmless components.[3] At the same time, there are some highly resistant strains in which DDT is not immediately decomposed and in which sizable amounts of the substance can be found in the blood and body tissues of living insects. In still other strains it appears that resistance or tolerance may be due largely to varied morphological characters or variations in habits rather than to chemical factors. It is therefore reasonable to expect that house fly strains of dissimilar origin produced under quite distinct environmental conditions will differ in their response to varied laboratory conditions.

Research on house fly resistance to chemicals is under way at many investigative centers, and, while the genetic aspects of the problem and the exact nature of resistance have not as yet been clearly defined, considerable progress is being made. There is reason to hope that better understanding of the variables encountered in resistance investigations will further the progress of research on house fly resistance to chemicals.

SALARIES OF OFFICE EMPLOYEES OF SOME PHYSICIANS FREED FROM CONTROLS

A recent amendment to the Defense Production Act apparently frees most physicians from the restrictions previously imposed on them as employers by wage and salary controls in the manner and amount they can compensate their office employees. The amendment in effect exempts from wage and salary controls "wages, salaries, or other compensation of persons employed in small-business enterprises," which the amendment defines as "any enterprise in which a total of eight or less persons are employed." Thus, physicians who employ eight or less persons in connection with the practice of medicine are freed from the confusing wage and salary controls and may now compensate and increase the compensation of their employees as they deem advisable.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

Last month I stated that many persons regard the American Medical Association as a pressure organization devoted to the interests of industry and management. There are two reasons for this impression. One is that during the last four years the Association has had to conduct a campaign to protect the freedom of medicine. This has been highlighted to the exclusion, from the minds of the public, of the Association's scientific activities. The other reason, in my opinion, is that we have been remiss in not keeping the people informed of all we are doing to raise the health level of the public. This remissness on our part existed long before we engaged in any campaign. Now that the intensity of the campaign against socialized medicine is about at an end, and with the recent reorganization of our Public Relations Department, I believe neither of these reasons will any longer be a factor.

Perhaps one of the best ways to demonstrate the amount of work the Association devotes to the furthering of the scientific aspects of medicine will be to show how the Association spends its income. Figures are rather dry, but they do tell the story. I shall use round figures only, so as to render them less confusing.

The total income of the Association from dues (less the amount allocated to subscriptions to THE JOURNAL), investments, and miscellaneous sources was approximately $1,958,000 for 1951. The income from subscriptions to and advertising in our scientific publications was roughly $5,781,000. From this latter figure, however, must be deducted the costs of production, including printing. These costs were about $3,613,000, leaving a total income on publications of $2,168,000. This, added to the dues and investment income of $1,958,000, gives us a working income of $4,126,000.

The American Medical Association Headquarters occupies a nine story building covering about two-thirds of a city block. It houses nearly 900 full-time employees. For what may be termed administrative purposes, the costs are roughly $227,000. Added to this there is a sum of about $208,000 for such items as annuities and depreciation. The Association maintains biographical records of everyone in medicine from the time he enters medical school until he dies. From this record is compiled the Amedican Medical Directory. Membership records are also maintained. The Association has to a certain extent lent financial support to the Student American Medical Association. The total of these activities amounts to another $158,000. When all of these are deducted from available income, approximately $3,533,000 is left for other activities.

On straight scientific activities, such as those of the Councils on Medical Education and Hospitals, Pharmacy and Chemistry, Foods and Nutrition, Physical Medicine and Rehabilitation, Industrial Health, Rural Health, Health Education, the Bureau of Investigation (which deals with frauds and charlatanism), the Committee on Cosmetics, the Commission on Chronic Illness, the Survey on Medical Education, the Library, the laboratories, the Scientific Sessions (including the Scientific Exhibits), and extra costs of publication of pamphlets and books, the Association spends roughly $1,300,000. Closely associated with the purely scientific activities are the work of the Council on Medical Service and the Bureau of Medical Economic Research. They work constantly in the socioeconomic fields, such as hospital and medical care insurance, care of veterans, care of the indigent, labor plans, and distribution of physicians. The total cost of these activities is $280,700. The Council on National Emergency Service, which is concerned with problems of mobilization and cooperates with federal agencies, spent nearly $40,000. A half-million dollars was given to the American Medical Education Foundation as a contribution to help support our medical schools. Hence, on scientific and semiscientific activities the Association spent about $2,121,000.

The Public Relations Department, including the Press Bureau, spent approximately $209,000; the Washington Office, $180,500; and $51,500 was spent by the Bureau of Legal Medicine and Legislation, which analyzes and reports on all enacted federal and state legislation and court decisions affecting medicine.

We have accounted, therefore, for $3,154,000. This leaves us approximately $1,000,000 to account for. Nearly half ($443,000) was added to capital. The balance, slightly over $500,000, was allotted to the National Education Campaign, which is being brought to a close this year. The amount of $2,121,000, spent on scientific and related activities, does not represent the real total, as much of the money spent by the Public Relations Department and the Press Bureau was devoted to disseminating scientific information.

Members of the Association sometimes ask how their dues are spent. Of the $25.00 paid by each individual member, $15.00 is allocated to cover the cost of his subscription to THE JOURNAL. That leaves $10.00 for other purposes. It was formerly possible to run the Association on subscriptions, advertising, income from investments and Fellowship dues. Fellowship dues no longer exist, as the Fellowship category has been abolished, although $228,000 was received from that source in 1951. If, however, we take the total amount available in 1951 from advertising, subscriptions, investment income, and income from miscellaneous sources, we shall find that there was available only $2,403,000. That would have been insufficient to cover the costs of the scientific and semiscientific activities, administration, and the membership-biographical services, which totaled over $2,840,000. Merely on these activities alone we should have had a deficit of nearly a half million dollars.

Where, then, can we cut down on our expenses? For each of the past two years the Association has contributed $500,000 to the American Medical Education Foundation. It has also absorbed all the expense of administration of the Foundation, which in 1951 amounted to over $14,000. This has been done so that every dollar contributed by any physician would go to the medical schools. Shall we discontinue this and have our medical schools become dependent on federal aid with all of its dangers? Not that the half million dollars the Association contributes will in itself prevent it, but it is a help in the general campaign for private support of medical education.

The National Education Campaign, which in 1951 expended $529,000, will be brought to a close this year. Out of these funds was spent the cost of the Presidential inaugural broadcast (about $30,000), at the Annual Meeting in 1951. This broadcast has been termed one of the best, if not the best of the public relations activities of the Association.

If we allocate the $25.00 paid by the individual member in 1951, we shall find that it was distributed as follows: $15.00 went to cover the cost of his subscription to THE JOURNAL; $5.14 to the scientific and semiscientific activities; $1.06 to administration; $0.39 to biographical and membership records; $1.07 to public relations, the Washington Office, and the Bureau of Legal Medicine; $1.07 to the capital of the Association; and $1.27 to the National Education Campaign. In 1953 the amount allotted to the National Education Campaign will probably be divided among the other activities in a relative proportion.

That, then, is what becomes of a member's dues. Can anyone submit a legitimate complaint against such a distribution? The whole environment of medical practice in this country today, high-standard medical education, high standards in therapeutic agents and apparatus, high quality of hospitals, protection against fraudulent remedies and charlatanism, high standards of medical care, and the right to practice in a free state are due to your Association. In addition you receive the outstanding medical publication in the world. Can any member think of any way in which to spend $25.00 and obtain greater return for his money?

LOUIS H. BAUER, M.D., Hempstead, N. Y.

ORGANIZATION SECTION

ASSOCIATION EXHIBITS

Health exhibits for fairs and expositions and other public gatherings have been scheduled for numerous showings during the next two months by the Bureau of Exhibits. These exhibits are shown with the cooperation of the various state or county medical societies. Medical exhibits for medical societies and other scientific groups have also been reserved for several occasions. The schedule is as follows:

Aug. 5 to 8,	"Home Accidents," Rural Health Conference, Little Rock, Ark.
Aug. 6 to 9,	"Diseases Transmitted from Animals to Man," Trumbull County Fair, Warren, Ohio.
Aug. 8 to 17,	"Animals in Research," "Voluntary Health Insurance," and "Mechanical Quackery," Illinois State Fair, Springfield, Ill.
Aug. 10 to 15,	"School Health," Miami County Fair, Bradford, Ohio
Aug. 11 to 15,	"The Failing Heart," Pocahontas County Fair, Marlinton, W. Va.
Aug. 13 to 16,	"You and Your Body," Clark County Fair, Springfield, Ohio
Aug. 16 to 24,	"Testing the Drinking Driver," Missouri State Fair, Sedalia, Mo.
Aug. 17 to 22,	"You and Your A. M. A.," American Pharmaceutical Association Meeting, Philadelphia
Aug. 18 to 24,	"Home Accidents," Sioux Falls, S. D.
Aug. 21 to Sept. 1,	"Testing the Drinking Driver," Iowa State Fair, Des Moines, Iowa
Aug. 25 to 30,	"You and Your Body," Dutchess County Fair, Rhinebeck, N. Y.
Sept. 3 to 6,	"The Failing Heart," Highland County Fair, Hillsboro, Ohio
Sept. 6 to 12,	"Home Accidents" and "Appendicitis," Kansas Free Fair, Topeka, Kan.
Sept. 7 to 9,	"You and Your A. M. A.," New Hampshire State Medical Society Meeting, Bretton Woods, N. H.
Sept. 8 to 9,	"Testing the Drinking Driver," Indianapolis Police Department, Indianapolis
Sept. 8 to 11,	"Testing the Drinking Driver," Institute of Traffic Engineers, Chicago
Sept. 9 to 13,	"Animals in Research," National Chemical Exposition, Chicago
Sept. 14 to 21,	"Mechanical Quackery," Massachusetts Medical Society, West Springfield, Mass.
Sept. 15 to 18,	"Medical Education," American Hospital Association Meeting, Philadelphia
Sept. 15 to 19,	"Home Accidents and Appendicitis," Kansas State Fair, Hutchinson, Kan.
Sept. 16 to 19,	"You and Your Body," Washington County Fair, Fayettesville, Ark.
Sept. 16 to 27,	"Testing the Drinking Driver," Virginia State Fair, Richmond, Va.
Sept. 19 to 28,	"You Can Reduce," Atlantic Rural Exposition, Richmond, Va.
Sept. 21 to 25,	"Testing the Drinking Driver," International Association of Police Chiefs, Los Angeles
Sept. 22 to 26,	"Medical Education," American College of Surgeons Meeting, New York
Sept. 28 to Oct. 1,	"Mechanical Quackery," Virginia Medical Association, Richmond

IF YOU CHANGE YOUR ADDRESS

Your copy of THE JOURNAL is addressed to you several days in advance of the publication date; so if you change your address, please notify us at least three weeks in advance.

Send your old address together with the new, preferably clipping the name and address from your last copy of THE JOURNAL.

Copies mailed to your old address will not be forwarded by the Post Office, unless you provide the Post Office with the forwarding fee.

Send your change of address to:

American Medical Association
THE JOURNAL Subscription Department
535 N. Dearborn St., Chicago 10.

USE OF GAMMA GLOBULIN IN PREVENTION OF PARALYTIC POLIOMYELITIS

The following statement has been issued by the chairman of the Sub-Committee on Blood of the Health Resources Advisory Committee of the Office of Defense Mobilization:

Whether gamma globulin will be effective in the prevention of paralytic poliomyelitis is not now known. On the basis of animal experiments and preliminary study on humans, it is possible that globulin will have value in human poliomyelitis, but serious questions remain to be answered before such a hope can be substantiated. Nevertheless, public dissemination of information on the status and objectives of current studies, which have been incompletely presented or misunderstood, has created a serious demand for gamma globulin that cannot be met.

Virtually the entire output at current production rates is required to meet the demand for prevention or modification of the course of measles and infectious hepatitis. Under the circumstances, it is obvious that the existing limited supply and current production of gamma globulin should be reserved for use in the diseases in which its efficacy has been established.

SURVEY OF RESEARCH PROJECTS

The A. M. A.'s Committee on Research will send out questionnaires early in September to determine what medical research projects currently are in progress in the United States. The survey has a threefold purpose: to establish an up-to-date file of medical research projects; to evaluate the premise that certain fields of medical research are suffering from lack of financial support; and to consider the actual contribution of individual scientists in terms of free time and personal expenditure of funds. A random sample of 15,000 physicians from all parts of the country and selected personnel from medical schools, public health services, and pharmaceutical firms will be asked to participate in the survey.

COMMISSION ON ACCREDITATION OF HOSPITALS OPENS OFFICE

Director Edwin L. Crosby, M.D., former superintendent of Johns Hopkins Hospital, Baltimore, will open the new Joint Commission on Accreditation of Hospitals office Sept. 1 at 660 Rush Street, Chicago. The commission, with representatives from the American Hospital Association, the American College of Surgeons, the American College of Physicians, the Canadian Medical Association, and the American Medical Association, will assume responsibility for the hospital standardization program formerly carried out by the American College of Surgeons. The commission's program will get under way early this fall.

THE JACOBI FUND

The Jacobi Fund of the Section on Pediatrics received $1,696 from 282 contributors, according to the report made at the June meeting in Chicago by Hugh L. Dwyer, M.D., Custodian. Net income from investments was $188.76. Expense and distribution to essayists was $731.80. Trust value May 30, 1952, was $6,890.04.

MEDICAL NEWS

ARIZONA

Infant Health Campaign.—To stimulate the organization of community health councils and committees for promotion of health clinics, the *Arizona Farmer* in Phoenix and the First National Bank of Arizona are sponsoring a statewide rural infant health campaign. One $100 and two $75 awards will be made to three rural organizations that make major contributions to the cause of infant health in Arizona between now and May 31, 1953. One of the $75 awards will go to an Indian organization in Arizona, and these organizations also will be eligible for either of the other two awards.

CALIFORNIA

Suicides in Los Angeles.—Los Angeles had a higher average suicide rate for the 10 year period 1941-1950 than the State of California (9% higher) and the United States as a whole (67% higher). The southern states have the lowest rates. Of 354 suicides in 1950 for Los Angeles residents, 265 (75%) were men.

Dr. Lewis to Study Health Conditions in Iran.—In response to a request from Iran for help in putting into effect its legislation for the protection of the health of workers, the World Health Organization and the International Labor Organization have jointly appointed Dr. Leon Lewis of Berkeley to survey health conditions in factories in Iran and to advise the ministry of health on how they can be improved. Dr. Lewis was formerly head of the division of industrial hygiene in the School of Public Health, University of California, Berkeley. In Iran he will study conditions among workers in mines, handicrafts shops, and carpet, match, and tea factories.

DISTRICT OF COLUMBIA

The Gibson Award.—At its annual banquet in the Williamsburg Room of the Mayflower Hotel, Washington, D. C., May 17, the Washington Medical and Surgical Society presented the Frank E. Gibson Award and a cash prize of $25 to Dr. James H. Scully of Washington, D. C., who had given the outstanding scientific paper before the society during the past year. The subject of his paper was "The Treatment of Metastatic Malignancy from Breast Cancer."

Dr. Beattie Accepts Chicago Appointments.—Dr. Edward J. Beattie Jr., of Washington, D. C., has been appointed clinical assistant professor of surgery (Rush) on the faculty of the University of Illinois College of Medicine, Chicago, and will also serve on the medical staff of Presbyterian Hospital in Chicago. Dr. Beattie was an instructor in surgery at Harvard Medical School, Boston, for two years before going to London, England, as a Moseley Traveling fellow to study medicine and cardiology. On his return, he became affiliated with George Washington University in Washington, D. C., where for the past five years he has been assistant professor of surgery and director of the surgical research laboratories. He also was consultant in thoracic surgery for five Washington, D. C., hospitals and was a Markle scholar.

ILLINOIS

Hospital Celebrates Golden Anniversary.—The St. Joseph Hospital in Elgin will celebrate its 50th anniversary on Sept. 24. Sister M. Melitta is administrator of the hospital, which has a bed capacity of 150 for adults and children and 30 bassinettes. There will be open house from 2 to 8:30 p. m.

Health Officer Appointed.—Dr. Albert L. Hildinger of Omaha has been appointed medical director for the Jo Daviess County Health Department, with offices at Galena. Dr. Hildinger has had seven years of experience in public health work in Nebraska, serving as health officer for the Sarpy-Otoe-Nemoha Tri-County Health Department and for the Scottsbluff County Health Department. Previously he was in private practice in Omaha for 14 years.

Chicago

Northwestern University Retirements.—On Sept. 1 three physicians will retire from the staff of Northwestern University Medical School. Dr. Karl A. Meyer, professor of surgery since 1945, has been affiliated with Northwestern since 1925. Dr. Arthur R. Metz, associate professor of surgery, has been on its staff since 1942. Dr. Frederick W. Merrifield has been professor of oral surgery in the dental school and assistant professor of surgery in the medical school since 1940.

Reception Honoring Dr. Bernhard Zondek.—The Chicago chapter of the American Jewish Physicians' Committee will hold a dinner and reception at the Standard Club Sept. 2 in honor of Dr. Bernhard Zondek, professor of gynecology and obstetrics at the Hebrew University Medical School, Jerusalem, Israel. Members of the sponsoring committee include Drs. Max Thorek, Nicholas I. Fox, Sidney O. Levinson, Heinrich Necheles, Lester E. Frankenthal Jr., Jacob S. Golden, Hymen I. Sapoznik, Sidney A. Portis, Salamon Boros, Joseph T. Bolotin, and Maurice S. Mazel. Dr. Morris Fishbein will be the toastmaster.

KENTUCKY

Psychiatric Leader Honored.—Dr. S. Spafford Ackerly, head, department. of psychiatry, University of Louisville School of Medicine, and medical director of the Louisville Mental Hygiene Clinic, was honored at a party given by former students, psychiatrists, social workers, and others interested in mental hygiene. He was presented with a silver tray inscribed "for twenty years of unselfishly dedicated service to his friends, profession, students, university, city, and state." He was also given an outboard motor.

MICHIGAN

State Medical Meeting in Detroit.—The annual session of the Michigan State Medical Society will be held at the Sheraton-Cadillac Hotel, Detroit, Sept. 24-26, under the presidency of Dr. Otto O. Beck of Birmingham. The Andrew P. Biddle Lecture will be delivered by Paul de Kruif, Ph.D., Holland, at 9:15 Wednesday evening, as a feature of Officers' Night, when the meeting will be open to the public. Other guest speakers include: Dr. Gaylord W. Anderson, Minneapolis; Drs. Claude S. Beck, Spencer Braden, and George Crile, Cleveland; Dr. John J. Bonica, Tacoma, Wash.; Dr. Ormond S. Culp, Rochester, Minn.; Dr. Daniel C. Darrow, New Haven, Conn.; Drs. Edwin J. De Costa, Peter C. Kronfeld, Roland P. MacKay, Philip Thorek, and Leonard F. Weber, Chicago; Dr. Garfield G. Duncan, Philadelphia; Dr. Carl W. Eberbach, Milwaukee; Drs. Dwight E. Harken, Duncan E. Reid, Samuel F. Marshall, and Claude E. Welch, Boston; Dr. Milton I. Levine, New York; Drs. Earl R. Miller and David A. Rytand, San Francisco; Dr. Emil Novak, Baltimore; Dr. Ben H. Senturia, St. Louis; and Dr. Evan W. Thomas, Albany, N. Y. Three discussion conferences or quiz periods will be held Wednesday, Thursday, and Friday in the Grand Ballroom from 12 noon to 1 p. m. All guest speakers of the day will be present on the platform.

Thursday evening, State Society Night, will afford entertainment in the Grand Ballroom. On Wednesday the Michigan branch of the Academy of Pediatrics will have a dinner and business meeting at 6:30 p. m. in the English Room; the Michigan State Medical Society Section on Ophthalmology and the Detroit Ophthalmological Society will meet for dinner at 7 p. m. in the Pan American Room, and the Detroit branch of the American Urological Association will have a dinner at 7:30 p. m. in Suite 500, preceded by a reception at 6:30 p. m. in the suite assigned to

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Dr. William Bromme, Detroit. "Upper Peninsula Day" will be celebrated with cocktails and dinner in parlors G, H, and I at 6 p. m.

On Thursday the Michigan Allergy Society will meet for dinner at 7:15 p. m., after which there will be a meeting at 8:30 p. m., addressed by Dr. Samuel M. Feinberg, Chicago, professor of medicine, Northwestern University Medical School. The Wayne University Alumni Association will hold its banquet at 6:30 p. m. in the English Room. The Michigan Regional Committee on Trauma, American College of Surgeons, will hold a meeting after its luncheon at 12 noon in the Pan American Room. The Michigan chapter of the American College of Chest Physicians will assemble for dinner at 7 p. m. in the Pan American Room. The directors of the Michigan Academy of General Practice will meet for dinner at 6 p. m. in Parlor F, and the Michigan chapter of the Arthritis and Rheumatism Foundation will hold a joint dinner meeting with the Michigan Rheumatism Society at 7 p. m. in the Founders' Room. The Michigan Pathological Society will hold a meeting from 2 to 4:30 p. m. in the Michigan Room of the Statler Hotel and will also have a dinner meeting in the same room at 6:30 p. m. This society will conduct a slide seminar on dermatological lesions, at which Dr. Elson B. Helwig of the Armed Forces Institute will act as moderator. On Friday the Michigan Society of Neurology and Psychiatry will hold a reception at 5:30 p. m. before its 7 o'clock dinner in the Pan American Room.

The Woman's Auxiliary to the Michigan State Medical Society will meet Sept. 22-25 at the Fort Shelby Hotel, Detroit, and the Michigan State Medical Assistants Society will hold its meeting Sept. 24-25 at the Tuller Hotel in Detroit.

MISSOURI

General Practitioners Study Club.—The following programs for 1952 have been arranged by the General Practitioners Study Club of Greater St. Louis:

Sept. 17, Roy V. Boedeker, Management of Abortion.
Oct. 15, Robert W. Bartlett, Differential Diagnosis and Treatment of Cancer of the Colon and Rectum.
Nov. 19, Maurice J. Lonsway, Newer Concepts in Pediatrics of Interest to General Practitioners.
Dec. 17, Garold V. Stryker, Common Skin Diseases.

Dr. Moore Heads Geographic Pathologists.—Dr. Robert A. Moore, dean, Washington University School of Medicine, St. Louis, and Edward Mallinckrodt professor of pathology, was elected president of the International Society of Geographic Pathology at its recent meeting in Liége, Belgium. The society is devoted to the study of geographic distribution of disease and discusses in detail one disease at each meeting. Epidemic jaundice was the topic at the Liége meeting; the next meeting in Washington, D. C., in September, 1954, will be concerned with cancer.

Dr. Moore also participated in a conference on lung cancer at the University of Louvain, Belgium, and, at the invitation of the United States Army, spent several days in Frankfurt, Germany, as consultant on pathology.

MONTANA

State Medical Meeting at Missoula.—The Montana Medical Association will hold its annual meeting at the Hotel Florence in Missoula, Sept. 18-21, under the presidency of Dr. Francis L. McPhail of Great Falls. Guest speakers will include Drs. Edward D. Allen and Lester R. Dragstedt, Chicago; Laurentius O. Underdahl, Rochester, Minn.; Roger W. Barnes, Los Angeles; John B. Grow, Kenneth D. A. Allen, and John C. Long, Denver; and Kenneth S. Landauer, New York. On Thursday and Friday at 12:15 p. m. there will be three panel discussions. Drs. Barnes and Edward Allen will be guest speakers at the panels on obstetrics, gynecology, and urology. These panels will be sponsored and conducted by the Montana Obstetrical and Gynecological Society. Drs. Dragstedt and Grow are guests for the panels in surgery, which will be sponsored and conducted by the Montana Chapter of the American College of Surgeons. The panels on internal medicine and radiology sponsored by the Montana-Wyoming Section of the American College of Physicians, will have as guest speakers Drs. Underdahl and Kenneth Allen.

Guest speakers at the banquet will be Dr. Louis H. Bauer, Hempstead, N. Y., President of the American Medical Association, who will discuss "Medicine, the Public and Citizenship," and O. Meredith Wilson, Ph.D., dean of the University College of the University of Utah, Salt Lake City, who will speak on "Western Regional Cooperation in Higher Education."

The Western Montana Medical Society will be host to members and guests of the Montana Medical Association at a fish fry Friday, 6 p. m., at the Missoula Country Club.

The woman's auxiliary will hold its annual meeting in Missoula at the Hotel Florence Sept. 18-19. Other organizations that will meet during the annual session include the Montana Urological Association, the Montana Obstetrical and Gynecological Society, and the Montana Academy of Oto-Ophthalmology. The Montana Physicians' Service will meet Sunday morning.

NEW YORK

Cancer Talks at Albany.—Albany Medical College announces that as part of the cancer teaching program Dr. Virginia K. Frantz of Columbia University College of Physicians and Surgeons, New York, will talk on "Carcinoma of the Thyroid" Sept. 26 from 12 to 1 p. m. Dr. J. Englebert Dunphy, associate professor of surgery, Harvard Medical School, Boston, will talk on "Observations on the Natural Course of Cancer" Oct. 24 from 12 to 1 p. m. These lectures at the college are open to the medical public.

Lectures on Occupational Medicine.—The faculty of medicine, Columbia University, announces a series of lectures on occupational medicine on Saturday mornings (6 to 10 a. m.) in Amphitheater A, College of Physicians and Surgeons, 630 W. 168th St., New York 32. Members of the medical and allied professions are invited. There will be no tuition fee.

The schedule is as follows:

Sept. 20, History of Occupational Medicine.
Sept. 27, Scope, Objectives and Practice of Occupational Medicine.
Oct. 4, Industrial Toxicology—General Principles.
Oct. 11, Toxic Metals I.
Oct. 18, Toxic Metals II.
Oct. 25, Toxic Solvents I.
Nov. 1, Toxic Solvents II.
Nov. 8, Toxic Dusts.
Nov. 15, Toxic Gases.
Nov. 22, Occupational Dermatoses and Infections.
Nov. 29, Ventilation, Lighting, Noise.
Dec. 6, Elementary Nuclear Physics; Radiation Hazards.
Dec. 13, Workmen's Compensation.

The order in which the topics are presented may be slightly modified depending on the availability of lecturers.

New York City

Hospital News.—Dr. Henry W. Kolbe, formerly medical superintendent of Harlem Hospital, has been appointed a general medical superintendent of the city department of hospitals, with over-all supervision of the 12 municipal hospitals in the boroughs of Brooklyn, Bronx, and Queens. Dr. Bernard B. Nadell, formerly medical superintendent of Lincoln Hospital, has replaced Dr. Kolbe as medical superintendent of Harlem Hospital, and Dr. Sander V. Smith, former deputy medical superintendent of Bellevue Hospital, has succeeded Dr. Nadell as medical superintendent of Lincoln Hospital.

Personal.—Dr. Paul F. Russell, representative in Italy of the Rockefeller Foundation, Division of Medicine and Public Health, was a guest lecturer during July at a World Health Organization Malaria Training Course in Lagos, Nigeria. Dr. Russell's address after Sept. 1 will be Rockefeller Foundation, 20 Rue de La Baume, Paris 8^{e}, France.——Dr. Frank R. Ferlaino, assistant clinical professor of industrial medicine, University Post-Graduate Medical School of the New York Bellevue Medical Center, has been appointed counselor of the New York Metropolitan District by the Industrial Medical Association.

PENNSYLVANIA

School Health Improvement.—A research program designed to improve the health of school children has been established at Pennsylvania State College with a grant of $35,000 from the Health Information Foundation, New York. According to Milton S. Eisenhower, LL.D., president of the college, and Adm. William H. P. Blandy, USN (Ret.), president of the foundation, methods will be sought of impressing parents with the importance of providing treatment for defects reported in school health examinations. In Pennsylvania, an examination is given each school child every other year, and notice of the observed defects is sent to the home with a request that parents take the child to a private doctor or dentist for treatment and report to the school when this is done. House-to-house studies in four communities revealed that, of 763 school children examined, 363 were found in need of treatment, but only 166 had received treatment. Various agencies of the state government as well as private organizations in the fields of health, welfare, and education will work with the research personnel. After information now available is assembled and the programs are observed, a symposium on the problem will be held.

Philadelphia

Gonorrhea Cases Increase.—Dr. James P. Dixon, health commissioner, reports a 13% increase in gonorrhea during the first half of the current year, a reversal of the downward trend for this disease begun in 1949. Gonorrhea topped the list of reportable diseases in Philadelphia during 1951, with 7,743 cases reported. Figures on the reporting of gonorrhea for continental United States show a decrease since Jan. 1. According to Dr. Dixon, special federal funds will be available within the next month to finance a project aimed at finding and treating Philadelphians infected with gonorrhea. One phase of the new project will be psychiatric examination of patients infected more than one time.

TEXAS

Another Twenty-Four Million Volt Betatron.—The M. D. Anderson Hospital for Cancer Research, Houston, will become the second hospital in the United States to have a 24 million volt betatron for treatment of patients and cancer research. The University of Illinois Research Hospital has a similar machine. Purchase of the machine for Anderson is made possible by grants totaling $121,000 from the U. S. Public Health Service's National Cancer Institute. Additional support for the second and third years of operation of the project has been committed depending on availability of public health funds at that time. Dr. Gilbert H. Fletcher, radiotherapist, and Peter Wooten, physicist, will be in charge of the research project involving the betatron.

UTAH

Annual State Medical Meeting.—The Utah State Medical Association will hold its annual meeting Sept. 4-6 in the Union Building of the University of Utah, Salt Lake City, under the presidency of Dr. Lewis W. Oaks of Provo. Out-of-state speakers will include:

Richard Ford, Boston, System and Technique for Investigation of Violent and Unexplained Death.
Charles P. Bailey, Philadelphia, Surgery of Mitral Valvular Disease.
Edgar M. Holmes, Boston, Diagnosis and Treatment of Facial Fractures.
Robert J. Bloor, Rochester, N. Y., X-Ray Diagnosis of Neoplasms of the Gastrointestinal Tract.
Walter G. Maddock, Chicago, Observations Leading to a Better Understanding of Gastrointestinal Distention.
William C. Keettel, Iowa City, Indication and Contraindication for Induction of Labor.
Roy H. Turner, New Orleans, 1. On Eating Fat. 2. Some Generalizations on Diagnosis of Liver Disease.

Luncheon meetings on Thursday and Friday will include round-table discussions. Movies will be shown at noon on Saturday and also at 12:45 p. m. Thursday and Friday. At 4 p. m. Friday there will be a meeting of the Utah chapter of the American Academy of General Practice, and at 7 p. m. the annual banquet will be held in the Hotel Utah.

Members of the medical corps of the U. S. Armed Forces in uniform are invited to attend the scientific sessions without registration fee. Other physicians, resident in Utah, who are not members of the Utah State Medical Association will be charged a registration fee equal to the current state dues.

WASHINGTON

State Medical Meeting in Seattle.—The Washington State Medical Association will hold its annual convention in Seattle at the Olympic Hotel, Sept. 13-17, under the presidency of Dr. Reuben A. Benson, Bremerton. The presidential address at 11:30 Tuesday will be followed by a talk by Dr. Ernest B. Howard, Chicago, Assistant Secretary of the American Medical Association. Guest speakers and their first presentations at the scientific session are as follows:

John H. Dingle, Cleveland, Viruses and Virus Diseases.
Dwight E. Harken, Boston, Responsibility of the Physician in Recognizing Surgical Mitral Heart Disease.
Edwin Jack Wylie, San Francisco, Surgical Revascularization in Arteriosclerotic Thrombosis.

The public relations luncheon at 12:30 Wednesday will be addressed by Dr. Lewis A. Alesen, Los Angeles, president-elect of the California Medical Association.

The section on ophthalmology and otolaryngology, which will meet on Wednesday, will have a symposium on "Retrolental Fibroplasia" at 9:40 a. m. and a panel discussion on "Lesions of the Mouth" at 11 o'clock.

The forum on fundamental problems Wednesday, 2:40-5 p. m., will include discussions on mitral commissurotomy, experimental pulmonary edema, candida (monilia) following treatment with antibiotics, fertility and sterility, mechanisms of muscle pain, psychophysiological aspects of colic, and diseases of the blood.

The nonscientific program includes a "no-host" family dinner on Sunday, during which the general practitioner's and past presidents' awards will be made; the salmon fishing derby, golf tournament, and sportsmen's banquet will take place on Monday. The banquet Tuesday will be followed by a dance. On Wednesday at 6:30 p. m. the president's reception will be held. The woman's auxiliary will hold its annual meeting at the Olympic Hotel Sept. 14-17.

WISCONSIN

Meeting of Ophthalmologists and Otolaryngologists.—The Central Wisconsin-Upper Michigan Society of Ophthalmology and Otolaryngology will meet at Maxwelton Braes, Bailey's Harbor, Door County, Sept. 6-7. On Saturday afternoon Dr. Noah D. Fabricant of Chicago will discuss "Current Trends in Medication of the Ear, Nose, and Throat," and Dr. William F. Hughes Jr., Chicago, will speak on "Repair of Lid Injuries, Including Entropion and Ectropion."

Cocktail hour at 6 p. m. precedes the dinner at which Dr. Fabricant will present "Amusing Quotations for Doctors and Patients." Sunday morning Dr. Hughes will read a paper on "Present Day Practice Regarding Orbital Implants After Enucleation" and present a movie on "The Technique of Implantation of Buried Polyvinyl Implants."

The meeting will conclude with luncheon at 12:30 p. m.

GENERAL

National Board Changes Address.—After Sept. 1 the National Board of Medical Examiners will be located at 133 S. 36th St., Philadelphia 4; telephone number, EVergreen 6-6704.

Malaria Reported.—Of 434 cases of malaria reported to the U. S. Public Health Service for the week ended Aug. 2, 62 occurred in civilians. Twenty of the 22 cases in California were reported in Veterans' Administration hospitals; in 12 of these the infection was of the tertian type, and in 9 the disease had been acquired in Korea. The patient in one civilian case was a Mexican national. Other states reporting five or more civilian cases of malaria were Oklahoma (11), Iowa (6), and Texas (5).

Death Certificates.—A booklet called "Medical Certification of Cause of Death," prepared by the World Health Organization, provides instructions for physicians on use of the medical certification of the cause of death. Since this country has adopted the international system of classification of causes of death, the booklet should prove useful in all vital statistics offices, in training programs in nosology, in assisting young physicians, and in programs of querying by mail.

Research in Arthritis.—The Arthritis and Rheumatism Foundation is offering research fellowships on both the predoctoral and postdoctoral levels in the basic sciences related to arthritis. Fellowships will run for one year with prospect of renewal. Predoctoral fellowships will range from $1,500 to $3,000 per annum, depending on the family responsibilities of the fellow, and postdoctoral fellowships from $3,000 to $6,000 on the same basis. Deadline for applications is Nov. 1, 1952. Applications will be reviewed and awards made by Feb. 15, 1953. For information address the Medical Director, The Arthritis and Rheumatism Foundation, 23 W. 45th St., New York 36.

Poliomyelitis in Other Countries.—The U. S. Public Health Service reports that the incidence of poliomyelitis has increased in Canada, principally in the four western provinces. Up to Aug. 4, 104 cases with five deaths were reported in the province of Alberta, and in the city of Calgary, 30 cases had occurred. The largest previous total (20) was reported in 1930. For the two weeks ended July 26, 26 cases were reported in Cuba, 21 of which were in the Province of Habana. About 80% of the cases reported are of the paralytic type. In the German Federal Republic, 492 cases were reported for the week ended July 26, as compared with 326 for the previous week. Switzerland reported more cases during the four weeks ended July 26 than during similar periods of 1950 and 1951.

Life Insurance Medical Research Fellowships.—Applications for awards available July 1, 1953, will be received by the Life Insurance Medical Research Fund as follows: 1. Applications for postdoctoral research fellowships will be accepted until Oct. 31, 1952. Preference is given to those who wish to work on cardiovascular function and disease or related fundamental problems. Stipends vary from $3,300 to $4,500. 2. Applications for grants to institutions in aid of research on cardiovascular problems will be accepted until Nov. 15, 1952. Support is available for physiological, biochemical, and other basic research on cardiovascular problems as well as for clinical investigation in this field. Information may be obtained from the Scientific Director, Life Insurance Medical Research Fund, 2 E. 103rd St., New York 29.

Anesthetists Meet in Virginia.—The Congress of the International Anesthesia Research Society will be held at Virginia Beach, Sept. 22-25, under the presidency of Dr. George J. Thomas, Pittsburgh. The following presentations will be accompanied by lantern slide demonstrations:

Robert M. Smith, Boston, Prevention of Tracheitis Following Endotracheal Intubation on Pediatric Anesthesia.
Francis F. Foldes, Pittsburgh, Role of Cholinesterase in Anesthesiology.
David M. Little Jr. and L. Jennings Hampton, New Haven, Conn., Diacetylcholine (Succinylcholine): A Controllable Muscle Relaxant.
Clarence L. Hebert, Staten Island, N. Y., Role of Anesthesiologist in Patient Care During the Immediate Postanesthesia-Postoperative Period.
Joseph Owens Hayes, Buffalo, Translaryngeal Anesthesia.
D. Dwight Grove and George E. Covintree, Philadelphia, Precautions with Gases Used by the Anesthesiologist Exclusive of Fire and Explosion Hazards.
Dexter R. Branch, Cambridge, Mass., Ether Anesthesia—A True Gas Vaporization Technique.

The sessions will close with a panel discussion on "Controlled Hypotension as an Adjunct to Surgery."

American Roentgen Ray Society.—The annual meeting of the American Roentgen Ray Society will be held at the Shamrock Hotel, Houston, Texas, Sept. 23-26, under the presidency of Dr. Charles L. Martin, Dallas, Texas, who will be installed at the meeting Tuesday morning. During the sessions 34 papers will be presented. Tuesday evening Dr. Edward B. D. Neuhauser of Boston will give the Caldwell Lecture on "Growth Differentiation and Disease." On Wednesday evening Dr. Clyde A. Stevenson of Temple, Texas, will serve as moderator for a film reading session. Collaborators will be Drs. Paul C. Hodges, Chicago, Fred J. Hodges, Ann Arbor, Mich., Merrill C. Sosman, Boston, and C. Allen Good, Rochester, Minn.

A golf tournament will be held Monday at the River Oaks Country Club. Arrangements for deep sea and other fishing trips may be made through a committee headed by Dr. Palmer Wigby, 506 Hermann Professional Bldg., Houston. Instruction courses will meet at 8:30 a. m. each day during the convention.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

FOREIGN

International Congress on Hearing Technique.—The first International Meeting on Hearing Technique will be held at Teatro dell'Opera, Casino Municipale in Sanremo, Italy, Sept. 21-28. The subjects to be discussed include street and factory noises, acoustic insulation in buildings, apparatus for testing simulation of deafness, artificial hearing apparatus, apparatus for teaching deaf people and backward children, and institutions to combat noises and deafness. Every participant will be enabled to hear all lectures and communications in his own language by means of headphones of the simultaneous translation apparatus. For information, contact Centro Audiotecnico Internazionale, C. P. 207, Sanremo, Italy.

All-India Obstetric and Gynaecological Congress.—The Seventh All-India Obstetric and Gynaecological Congress will be held Dec. 15-17 in Calcutta. The chief subjects for discussion will be "Cephalopelvic Disproportion" and "Nonmalignant Lesions of the Cervix." Obstetric and gynecologic societies of India and abroad, as well as teaching institutions and practitioners in the profession, are invited to take part in the conference. Those who desire to present papers on either of the main subjects are requested to communicate the title to the secretary's office of the Bengal Obstetric and Gynaecological Society, 91B, Chittaranjan Ave., C. M. C. House, Calcutta 12, by Oct. 15 and to submit a typed copy of the paper with abstracts by the end of October.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 23-25. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery.

Alaska:* *Examination.* Juneau. On application in other towns where there are board members. *Reciprocity.* On application. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

Arkansas:* *Examination.* Little Rock, Nov. 6-7. Sec., Dr. Joe Verser, Harrisburg.

California: *Written.* Sacramento, Oct. 20-23. Application must be received at least two weeks prior to date of examination. *Oral for Reciprocity Applicants.* San Francisco, Nov. 8. Applicants are requested not to arrange to come to an oral examination until they receive notice from the Credentials Committee. *Oral and Clinical for Foreign Medical School Graduates.* San Francisco, Nov. 9. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento.

Colorado:* *Reciprocity.* Denver, Oct. 14. Exec. Sec., Mrs. B. H. Hudgens, 831 Republic Bldg., Denver.

District of Columbia:* *Reciprocity.* Washington, Sept. 8. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Florida:* *Examination.* Jacksonville, Nov. 23-25. Sec., Dr. Homer L. Pearson, 701 Dupont Bldg., Miami 32.

Georgia: *Reciprocity.* Atlanta, Oct. 14-15. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Ex. Sec., Dr. Austin W. Matthis, Agana.

Illinois: *Examination.* Chicago, Sept. 23-25. Supt. of Regis., Mr. Charles F. Kervin, Capitol Bldg., Springfield.

Kansas: Topeka, Dec. 10-11. Sec., Dr. O. W. Davidson, 864 New Brotherhood Bldg., Kansas City.

Maryland: *Examination.* Baltimore, Dec. 9-12. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore 1.

Michigan:* *Examination.* Lansing, Oct. 8-10. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing.

Minnesota:* Minneapolis, Oct. 21-23. Sec., Dr. J. F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, December. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson 113.

Montana: Helena, Oct. 6-8. Sec., Dr. S. A. Cooney, 214 Power Block, Helena.

Nebraska:* *Examination.* Omaha, June 1953. Director, Mr. Husted K. Watson, Room 1009 State Capitol Bldg., Lincoln 9.

New Hampshire: Concord, Sept. 10. Sec., Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: *Examination.* Trenton, Oct. 21-24. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

North Carolina: *Reciprocity.* Durham, Oct. 13. Sec., Dr. Joseph J. Combs, 419 Professional Bldg., Raleigh.

Ohio: *Reciprocity.* Columbus, Oct. 7. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

South Carolina: *Reciprocity.* Columbia, Sept. 3. Sec., Mr. N. B. Heyward, 1329 Blanding St., Columbia.

Tennessee:* *Examination.* Memphis, Oct. 1-2. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

Virginia: *Examination.* Richmond, Dec. 11-13. *Reciprocity.* Richmond, Dec. 10. Sec., Dr. K. D. Graves, 631 First St., S.W., Roanoke, Va.

West Virginia: Charleston, Oct. 13-14. Sec., Dr. N. H. Dyer, State Office Bldg #3, Charleston 5.

Wyoming: Cheyenne, Oct. 6. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

Virgin Islands: *Examination.* St. Thomas, Nov. 12-13. Sec., Dr. Earle M. Rice, St. Thomas.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: *Examination.* On application. Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arizona: *Examination.* Tucson, Sept. 16. Sec., Mr. Herbert D. Rhodes, Room 423, Liberal Arts Bldg., University of Arizona, Tucson.

Arkansas: *Examination.* Little Rock, Oct. 1-2. Sec., Mr. Louis E. Gebauer, 1002 Donaghey Bldg., Little Rock.

Colorado: *Examination.* Denver, Sept. 10-11. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

Connecticut: New Haven, Oct. 11. Address: State Board of Healing Arts, 110 Whitney Ave., New Haven 10.

District of Columbia: *Examination.* Washington, Oct. 20-21. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Florida: *Examination.* Gainesville, Oct. 25. Sec., Mr. M. W. Emmel, Box 340, University of Florida, Gainesville.

Michigan: *Examination.* Detroit and Ann Arbor, Oct. 10-11. Sec., Mrs. Anne Baker, 423 W. Michigan Ave., Lansing.

Minnesota: *Examination.* Minneapolis, Oct. 7-8. Sec., Mr. Raymond N Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, Oct. 7-8. Director, Bureau of Examining Boards, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

New Mexico: *Examination.* Santa Fe, Sept. 21. Sec., Mrs. Marguerite Cantrell, Box 1592, Santa Fe.

Oklahoma: *Examination.* Oklahoma City, Sept. 13. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, Sept. 6 and Dec. 6. Sec., Dr. Charles D. Byrne, State Board of Higher Education, University of Oregon, Eugene.

South Dakota: *Examination.* Vermillion, Dec. 5-6. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Tennessee: *Examination.* Memphis, Sept. 24-25. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

Texas: *Examination.* Austin, October. Sec., Brother Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination.* Madison, Sept. 13, Milwaukee, Dec. 6. Sec., Mr. W. H. Barber, 621 Ransom St., Ripon.

---

* Basic Science Certificate required.

MEETINGS

American Medical Association Public Relations Institute, Edgewater Beach Hotel, Chicago, Sept. 4-5. Mr. Leo E. Brown, 535 N. Dearborn St., Chicago 10, Director.

American Academy for Cerebral Palsy, Durham, N. C., Oct. 2-4. Dr. Meyer A. Perlstein, 4743 North Drake Ave., Chicago 25, Secretary.

American Academy of Ophthalmology and Otolaryngology, Chicago, Oct. 12-17. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

American Academy of Pediatrics, Palmer House, Chicago, Oct. 20-23. Dr. E. H. Christopherson, 610 Church St., Evanston, Ill., Secretary.

American Association of Blood Banks, Hotel Schroeder, Milwaukee, Oct. 9-11. Miss Marjorie Saunders, 3500 Gaston Avenue, Dallas 1, Texas, Secretary.

American Association of Medical Record Librarians, Shoreham Hotel, Washington, D. C., Oct. 13-17. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, The Homestead, Hot Springs, Va., Sept. 4-6. Dr. William F. Mengert, 2211 Oak Lawn Ave., Dallas, Texas, Secretary.

American Clinical and Climatological Association, Elmira, N. Y., Oct. 16-18. Dr. Marshall N. Fulton, 124 Waterman St., Providence 6, R. I., Secretary.

American College of Surgeons, Waldorf-Astoria, New York, Sept. 22-26. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Secretary.

American Fracture Association, Hotel Sherman, Chicago, Oct. 6-9. Dr. H. W. Wellmerling, 219 N. Main St., Bloomington, Ill., Secretary.

American Hospital Association, Philadelphia, Sept. 15-18. Mr. George Bugbee, 18 East Division St., Chicago 10, Executive Director.

American Medical Writers' Association, Jefferson Hotel, St. Louis, Oct. 1. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

American Physiological Society, New Orleans, Sept. 4-6. Dr. E. F. Adolph, University of Rochester School of Medicine and Dentistry, Rochester, N. Y., Secretary.

American Public Health Association, Public Auditorium, Cleveland, Oct. 20-24. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American Roentgen Ray Society, Shamrock Hotel, Houston, Texas, Sept. 23-26. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

American Society of Clinical Pathologists, Chicago, Oct. 13-17. Dr. Clyde G. Culbertson, 1040 W. Michigan St., Indianapolis, Secretary.

American Society of Maxillofacial Surgeons, Hotel del Coronado, San Diego, Calif., Sept. 10-13. Dr. Casper M. Epsteen, 25 East Washington St., Chicago 2, Secretary.

Annual Gulf Coast Regional Conference on Industrial Health, Rice Hotel, Houston, Tex., Sept. 24-27. Dr. W. H. Hamrick, P. O. Box 2371, Houston, Tex., Chairman.

Association of Life Insurance Medical Directors of America, Los Angeles, Oct. 21-23. Dr. Henry B. Kirkland, P. O. Box 594, Newark 1, N. J., Secretary.

Biological Photographic Association, Hotel New Yorker, New York, Sept. 10-12. Mr. Lloyd E. Varden, Pavelle Color, Inc., 533 W. 57th St., New York 19, Secretary.

College of American Pathologists, Drake Hotel, Chicago, Oct. 13-17. Dr. M. G. Westmoreland, 203 N. Wabash Ave., Chicago 1, Executive Secretary.

Colorado State Medical Society, Stanley Hotel, Estes Park, Sept. 9-12. Mr. Harvey T. Sethman, 835 Republic Bldg., Denver 2, Executive Secretary.

Constantinian Society, Lake Placid Club, Lake Placid, N. Y., Oct. 1-4. Dr. C. F. Shook, P. O. Box 1035-36, Toledo 1, Ohio, Secretary.

Delaware, Medical Society of, Rehoboth, Sept. 8-10. Dr. Andrew M. Gehret, 822 North American Bldg., Wilmington, Secretary.

District of Columbia, Medical Society of the, Hotel Statler, Washington, Sept. 29-Oct. 1. Mr. Theodore Wiprud, 1718 M St. N.W., Washington, Secretary.

Great Falls Medical-Surgical Conference, Great Falls, Mont., Oct. 24-25. Dr. William E. Sullens, Box 1066, Great Falls, Mont., Chairman.

Gulf Coast Clinical Society, San Carlos Hotel, Pensacola, Fla., Oct. 16-17. Dr. Dale E. York, 21½ E. Wright St., Pensacola, Fla., Secretary.

Kansas City Southwest Clinical Society, Kansas City, Mo., Oct. 6-9. Dr. Galen M. Tice, 630 Shukert Bldg., Kansas City, Kansas, Secretary.

Kentucky State Medical Association, Brown Hotel, Louisville, Oct. 7-9. Dr. Bruce Underwood, 620 S. Third St., Louisville 2, Secretary.

Michigan State Medical Society, Book-Cadillac Hotel, Detroit, Sept. 24-26. Dr. L. Fernald Foster, 606 Townsend St., Lansing 15, Secretary.

Mississippi Valley Medical Society, Jefferson Hotel, St. Louis, Oct. 1-3. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Montana Medical Association, Florence Hotel, Missoula, Sept. 18-21. Mr. L. R. Hegland, 104 North Broadway, Billings, Executive Secretary.

National Gastroenterological Association, Hotel Statler, New York, Oct. 20-22. Dr. Sigurd W. Johnsen, 1819 Broadway, New York 23, Secretary.

Neurosurgical Society of America, The Cloister, Sea Island, Ga., Sept. 18-20. Dr. C. D. Hawkes, 22 North Manassas St., Memphis 5, Tenn., Secretary.

New Hampshire Medical Society, Mt. Washington Hotel, Bretton Woods, Sept. 7-9. Dr. Deering G. Smith, 44 Chester St., Nashua, Secretary.

North Pacific Pediatric Society, Challenger Inn, Sun Valley, Idaho, Sept. 19-20. Dr. S. Gorham Babson, 1107 S.W. 13th Ave., Portland 5, Ore., Secretary.

North Pacific Society of Internal Medicine, Sun Valley, Idaho, Sept. 19-20. Dr. Robert L. King, 1115 Terry Ave., Seattle 1, Wash., Secretary.

North Texas-Southern Oklahoma Fall Clinical Conference, Wichita Falls, Texas, Sept. 17. Dr. E. Aubrey Cox, Hamilton Bldg., Wichita Falls, Texas, Chairman.

Oregon State Medical Society, Portland, Oct. 8-11. Dr. Robert F. Miller, 833 S.W. 11th Ave., Portland 5, Secretary.

Pennsylvania, Medical Society of the State of, Bellevue-Stratford Hotel, Philadelphia, Sept. 28-Oct. 2. Dr. Walter F. Donaldson, 500 Penn Ave., Pittsburgh 22, Secretary.

Southwestern Surgical Congress, Baker Hotel, Dallas, Texas, Oct. 20-22. Miss June Marchant, 1227 Classen St., Oklahoma City, Executive Secretary.

Tri-State Medical Society of Texas, Louisiana and Arkansas, Texarkana, Texas, Oct. 2-3. Dr. Albert M. Hand, 619 Main St., Texarkana, Texas, Secretary.

U. S. Chapter, International College of Surgeons, Conrad Hilton Hotel, Chicago, Sept. 2-5. Dr. Arnold S. Jackson, 1516 Lake Shore Drive, Chicago, Executive Secretary.

Utah State Medical Association, Salt Lake City, Sept. 4-6. Dr. T. C. Weggeland, 42 S. Fifth East St., Salt Lake City, Secretary.

Vermont State Medical Society, Mt. Washington Hotel, Bretton Woods, N. H., Sept. 7-9. Dr. James P. Hammond, 128 Merchants Row, Rutland, Secretary.

Virginia, Medical Society of, Jefferson Hotel, Richmond, Sept. 28-Oct. 1. Mr. Robert L. Howard, 1105 West Franklin St., Richmond, Executive Secretary.

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 13-17. Dr. Bruce Zimmerman, 338 White-Henry-Stuart Bldg., Seattle, Secretary.

Wisconsin, State Medical Society of, Hotel Schroeder, Milwaukee, Oct. 6-8. Mr. Charles H. Crownhart, 704 E. Gorham St., Madison, Secretary.

INTERNATIONAL

Aero Medical Association Interim Meeting, Paris, France, Sept. 26-28. Dr. Armand Robert, 2 Rue Marbeuf, Paris 8e, France, Secretary.

American Congress of Industrial Medicine, Rio de Janeiro, Brazil, Sept. 20-28. Prof. Dr. Jose Pedro Reggi, Calle Arenales No. 981 Buenos Aires, Argentina, Director General.

Congress of International Anesthesia Research Society, Virginia Beach, Virginia, U. S. A., Sept. 22-25.

European Congress of Cardiology. University of London, Bloomsbury, W.C.1, England, Sept. 10-12. Dr. K. Shirley Smith, 35 Wimpole St., London, W.1, England, Secretary.

European Society of Cardiovascular Surgery, Strasbourg, France, Oct. 3-4. Sir James Learmonth, Department of Surgery, University New Buildings, Edinburgh 8, Scotland.

Interamerican Cardiological Congress, Buenos Aires, Argentina, Aug. 31-Sept. 7. Dr. Blas Moia, Larrea 1132, Buenos Aires, Argentina, Secretary-General.

Inter-American Congress of Public Health, Havana, Cuba. Sept. 26-Oct. 1. Pan-American Sanitary Bureau, 1501 New Hampshire Ave. N.W., Washington 6, D. C.

Inter-American Congress of Radiology, Mexico City, Mexico, Nov. 2-8. Dr. Guido Torres Martinez, Marsella No. 11, Mexico, D.F., Secretary-General.

International Congress of Anthropology and Ethnology, Vienna, Austria, Sept. 1-8. For information write: Secretaries, Royal Anthropological Institute, 52 Upper Bedford Place, London, W.C.1, England.

International Congress of Haematology, Mar del Plata, Argentina, Sept. 21-26. Dr. Carlos Reussi, Anchorena 1710, Buenos Aires, Argentina, Secretary.

International Congress of the History of Medicine, Nice-Cannes, France, and Monaco, Sept. 8-14. Dr. F. A. Sondervorst, 124 Avenue des Allies, Louvain, Belgium, Secretary-General.

International Congress on Hydatid Disease, Santiago, Chile, Nov. 21-24. Organizing Committee, P. O. Box 9183, Santiago, Chile.

International Congress of Internal Medicine, Friends House, London, N.W.1, Eng. Sept. 15-18. Sir Harold Boldero, 12 Pall Mall East, London, S.W.1, England, Secretary.

International Congress for Medical Librarians, London, England, July 20-25, 1953. Mr. W. R. LeFanu, % London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1, England, Chairman.

International Congress of Medical Press, Venice, Italy, Oct. 4-5. Dr. Bruno de Biasio, S. Marco 4646, Venice, Italy, Secretary.

International Congress on Medical Records, London, England, Sept. 7-12. Miss Gwen Perkins, 120 C Street S.E., Washington, D. C., Chairman.

International Congress of Military Medicine and Pharmacy, Montevideo, Uruguay, March 1-7, 1953. Dirreccion General del Servico de Sanitad Militar, 8 de Octubre y Mariano Moreno, Montevideo, Uruguay, Secretariat of the Congress.

International Congress on Neuropathology, Rome, Italy, Sept. 8-13. Dr. Armando Ferraro, 722 W. 168th St., New York, N. Y., U. S. A., Secretary General.

International Congress of Otorhinolaryngology, Amsterdam, Netherlands, June 8-15, 1953. Dr. W. H. Struben, J. J. Viottastraat 1, Amsterdam, Netherlands, Secretary.

International Congress of Radiology, Copenhagen, Denmark, July 19-25, 1953. Professor Flemming Norgaard, 10 Oster Voldgade, Copenhagen K., Denmark, Secretary General.

International Congress of Therapeutics, Madrid, Spain, Oct. 16-18. Professor Armijo, Instituto de Farmacología, Cuidad Universitaria, Madrid, Spain, Secretary.

International Congress of Urology, The Waldorf-Astoria, New York, N. Y., U. S. A., Sept. 15-18. Dr. John A. Taylor, 2 East 54th St., New York, N. Y., U. S. A., Secretary-General.

International Hospital Congress, London, England, May 25-30, 1953. Capt. J. E. Stone, 10 Old Jewry, London, EC2, England, Hon. Secretary.

International Study Conference on Child Welfare, Bombay, India, Dec. 5-12. For information write: All India Save the Children Committee, 5 Carmichael Road, Bombay, India.

Medical Women's International Association, Vichy, France, Sept. 12-16. Dr. Margaret M. Wurts, 27 East Wellesley Road, Montclair, N. J., U. S. A., National Secretary.

Neuroradiological Symposium, Stockholm, Sweden, Sept. 17-20. Docent Ake Lindbom, Symposium Neuroradiologicum, Serafimerlasarettet, Stockholm K., Sweden, Secretary.

Pan American Congress of the Medical Press, Buenos Aires, Argentine, July 12-16, 1953. Secretaria del Congress, 763 Uriburu, Buenos Aires, Argentine.

World Congress of Medicine, Montecatini, Italy, Oct. 16-18. Secretariat: Corso Trieste, 65, Rome, Italy.

World Medical Association, Athens, Greece, Oct. 12-16. Dr. Louis H. Bauer, 2 East 103d St., New York 29, N. Y., Secretary General.

DEATHS

Sutton, Richard Lightburn ⊕ McAllen, Texas; professor emeritus of dermatology at the University of Kansas School of Medicine in Kansas City, Kan.; lieutenant (jg) U. S. Navy, retired; born in Rockport, Mo., July 9, 1878; University Medical College of Kansas City, Mo., 1901; George Washington University School of Medicine, Washington, D. C., 1904; veteran of the Spanish-American War; entered the U. S. Navy Feb. 17, 1903, and was retired June 30, 1905 for incapacity resulting from an incident of the Service; at one time practiced in Kansas City, Mo., where he was affiliated with the Kansas City General, Bell Memorial, and St. Luke's hospitals; Associate Fellow and in 1913-1914 Chairman of the Section on Dermatology of the American Medical Association; past president of the Jackson County (Mo.) Medical Society; member of the American Dermatological Association, Missouri State Medical Association, and French Geographic Society; life fellow of the Royal Geographical Society of Great Britain; fellow of the Royal Society of Edinburgh; corresponding member of the Swedish Dermatological Society; specialist certified by the American Board of Dermatology and Syphilology; trustee of the Kansas City Museum and member of the board of directors of the Salvation Army in Kansas City, Mo.; special representative with the department of natural history, University of Missouri, African Expedition in 1923-1924 and expeditions for the same department to Indo-China and India, 1925-1926; was head of an African-Asiatic expedition in 1929-1930, Arctic expedition, north of Spitsbergen, as special representative, department of natural history, University of Kansas in 1932; conducted several expeditions to New Zealand and Australia, investigating habits of swordfish, and to Peru in 1941; in 1939 was with East Arctic Patrol, Northwest Territories, to Ellesmere Island, Somerset Island, and Baffinland; received the degree of LL.D. from the University of Missouri in 1922 and the honorary degree of Sc.D. from Washburn College, Topeka, in 1925; author of "African Holiday" 1924, "Tiger Trails in Southern Asia" 1926, "The Long Trek, Around the World With Camera and Rifle" 1930, "Arctic Safari: With Camera and Rifle in the Land of the Midnight Sun" 1932; co-author with Dr. Richard L. Sutton Jr., "Diseases of the Skin" (10th edition) 1939, "An Introduction to Dermatology" (4th edition) 1941, "Synopsis of Diseases of the Skin" 1942, and "Handbook of Diseases of the Skin" 1949, part two, 1950; author of "Silver Kings of Aransas Pass and Other Stories" 1937, section on "The Mycoses in Tice's System of Medicine" 1919, rewritten with Dr. R. L. Sutton Jr., in 1940, "Collected Verse" 1946, and also numerous scientific articles in American and foreign journals; died in Baylor University Hospital, Dallas, May 18, aged 73.

Slaughter, Donald Horace ⊕ Vermillion, S. D.; born in Shelby, Iowa, July 13, 1905; State University of Iowa College of Medicine, Iowa City, 1929; since 1946 dean and professor of pharmacology at University of South Dakota School of Medical Sciences; acting dean, Southwestern Medical College of the Southwestern Medical Foundation, Dallas, Texas, 1943-1944, when he became dean of students, professor of pharmacology, and chairman of the department of pharmacology and physiology, serving until 1946; professor of pharmacology and physiology and chairman of the department at the University of Vermont College of Medicine in Burlington, 1942-1943; formerly associate professor of pharmacology at Baylor University College of Medicine, Dallas, Texas; instructor in pharmacology at his alma mater from 1929 to 1931 and associate from 1932 to 1937; in 1942 received the Certificate of Merit from the Scientific Exhibit of the American Medical Association for his original investigation on a quantitative pain threshold machine; fellow of the American Association for the Advancement of Science; member of the American Society for Pharmacology and Experimental Therapeutics, Society of Experimental Medicine and Biology, serving as secretary of its Southwest Section, American Association of University Professors, New York Academy of Science, American Chemical Society, Omega Beta Pi, Alpha Kappa Kappa, Alpha Omega Alpha, and Sigma Xi; died June 6, aged 46.

Eaton, H. Douglas ⊕ Los Angeles; born in New York March 14, 1886; Columbia University College of Physicians and Surgeons, New York, 1911; formerly associate clinical professor of medicine (neurology), University of Southern California School of Medicine; specialist certified by the American Board of Psychiatry and Neurology; member of the Central Neuropsychiatric Association; examiner for the commission of psychiatry of Los Angeles County; a consultant for the Los Angeles police pension board, and the Pacific Electric Railway; consulting psychiatrist to Occidental College; during World War II served as consulting psychiatrist to the Selective Service Board, and held a commission in the U. S. Public Health Service; member of the staff of the Good Samaritan Hospital, and one of the founder members of the Good Hope Clinic; for many years an active member of the staff of the Children's Hospital, having been elected chief of the neurological service at the time of its inception; died May 24, aged 66, of coronary occlusion.

Hawkins, Arthur Hanson ⊕ Cumberland, Md.; born in La Plata, Md., Dec. 27, 1868; College of Physicians and Surgeons, Baltimore, 1895; an Associate Fellow of the American Medical Association; past president of the Allegany-Garrett Counties Medical Society and the Medical and Chirurgical Faculty of Maryland; fellow of the American College of Surgeons; member of the Southern Medical Association; during World Wars I and II served as chairman and surgeon of the Selective Service Medical Advisory Board; consulting surgeon, Miners Hospital, Frostburg, and Hazel McGilvery Hospital in Meyersdale, Pa.; affiliated with Memorial Hospital, where he was chairman of the Army examining board, and where he died June 9, aged 83, of hypertension, cardiovascular renal disease, and uremia.

Miller, Richard Henry ⊕ Boston; born in 1884; Harvard Medical School, Boston, 1910; member of the House of Delegates of the American Medical Association from 1935 to 1938 and from 1941 to 1944; at one time on the faculty of his alma mater; member of the founders group of the American Board of Surgery; member of the American Surgical Association and the New England Surgical Society; fellow of the American College of Surgeons; served during World War I; consulting surgeon, Massachusetts General and Boston Lying-In hospitals in Boston, Henry Heywood Memorial Hospital in Gardner, Leominster Hospital in Leominster, Mass., and Memorial Hospital in Pawtucket, R. I.; died June 3, aged 67.

Heyward, Nathan Barnwell ⊕ Columbia, S. C.; born in Columbia, S. C., Dec. 27, 1886; Columbia University College of Physicians and Surgeons, New York, 1911; examiner in bacteriology and pathology, state board of medical examiners, of which he was a member for many years and in recent years secretary; formerly secretary of the South Carolina Medical Association; past president of the Columbia Medical Society; an associate of the American College of Physicians; member of the consulting staff, Providence Hospital; member of the visiting staff, Columbia Hospital and South Carolina Baptist Hospital, where he died June 3, aged 65, of coronary thrombosis.

Heim, Hugh Wilson ⊕ Nanticoke, Pa.; born in Schuylkill Haven, Pa., Aug. 20, 1911; Jefferson Medical College of Philadelphia, 1935; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; served during World War II; consulting surgeon, Good Samaritan Hospital, Pottsville, Retreat State Hospital in Retreat, and Wyoming Valley Homeopathic Hospital in Wilkes-Barre; surgeon, Nesbitt Memorial Hospital in Kingston, and Wilkes-Barre General Hospital in Wilkes-Barre; surgeon in chief and chief of staff, Nanticoke State Hospital; died July 1, aged 41, of essential hypertension.

⊕ Indicates Member of the American Medical Association.

Englehart, Charles Clayton ⊕ Houghton, Mich.; Temple Univerversity School of Medicine, Philadelphia, 1931; affiliated with St. Joseph's Hospital in Hancock; died recently, aged 52, of coronary thrombosis.

Handmacher, Benjamin Berolf, Ambridge, Pa.; University of Wooster Medical Department, Cleveland, 1906; died in Sewickley recently, aged 69, of carcinoma of the stomach.

Hassett, Myron Frederick ⊕ St. Paul; University of Minnesota Medical School, Minneapolis, 1932; died in Riverview Memorial Hospital April 23, aged 46, of dissecting aneurysm and hypertension.

Heberer, Joseph M. ⊕ Evansville, Ind.; Louisville (Ky.) Medical College, 1900; died April 2, aged 73, of cerebral hemorrhage and hypertensive cardiovascular disease.

Schafer, Robert ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1925; served in the European theatre during World War II; on the staff of South Chicago Community Hospital, where he died May 1, aged 53, of acute glomerulonephritis.

Schanze, Raymond Andrew, Homerville, Ga.; University of Louisville (Ky.) School of Medicine, 1933; died in University Hospital, Augusta, May 1, aged 43, of heart disease.

Shailer, Sumner, Clearwater, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; died recently, aged 77, of arteriosclerotic heart disease.

Sheldon, Benjamin Burt, New York; New York Homeopathic Medical College and Hospital, New York, 1900; died in Apopka, Fla., recently, aged 84, of bronchopneumonia and arteriosclerosis.

Simon, John Sr. ⊕ Englewood, Colo.; Denver and Gross College of Medicine, 1907; served as mayor; affiliated with Mercy Hospital and Porter Sanitarium and Hospital in Denver; died May 2, aged 76, of acute coronary thrombosis.

Skrabucha, William Albert ⊕ Lowell, Mass.; Middlesex University School of Medicine, Waltham, 1935; affiliated with St. Joseph's Hospital; accidentally drowned in Lakewood April 30, aged 41.

Sloan, Ambrose Victor ⊕ Wilkes-Barre, Pa.; McGill University Faculty of Medicine, Montreal, Canada, 1924; served with the Canadian Army in France and Belgium during World War I; on the staff of the Mercy Hospital; died May 7, aged 56, of coronary occlusion.

Smith, Racy Hawkins, Lincolnton, Ga.; University of Georgia Medical Department, Augusta, 1925; affiliated with Washington (Ga.) General Hospital; died May 4, aged 53, in an automobile accident.

Snelson, Andrew J., Checotah, Okla. (licensed in Oklahoma by years of practice); affiliated with Oklahoma Baptist Hospital in Muskogee; died May 4, aged 90, of myocardial degeneration.

Somers, Pearl Ellsworth ⊕ Tullahoma, Tenn.; Rush Medical College, Chicago, 1897; member of the Iowa State Medical Society; past president of the Poweshiek County (Ia.) Medical Society; died April 4, aged 81, of Parkinson's disease and pneumonia.

Somme, Joseph, New York (licensed in New York, year unknown); died April 28, aged 85, of arteriosclerotic heart disease.

Steinmetz, Bruno, New York; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1920; died April 9, aged 57, of cancer.

Stewart, James A., Portal, Ga.; University of Georgia Medical Department, Augusta, 1906; died recently, aged 71, of uremia, hypertension, and arteriosclerosis.

Stripp, Albert Edward, Billings, Mont.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; formerly mayor of Laurel; served as city health officer; died May 7, aged 75.

Taddiken, Paul Gerald ⊕ Ogdensburg, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1895; served on the staff of St. Lawrence State Hospital; died May 2, aged 78, of uremia, chronic nephritis, and hypertrophy of the prostate.

Templeton, Charles A., Glendora, Calif.; Rush Medical College, Chicago, 1895; died recently, aged 83, of cerebral thrombosis.

Thomas, Ernest, Quinton, Okla.; University of Arkansas School of Medicine, Little Rock, 1911; served on the staffs of the McAlester General and St. Mary's hospitals; died May 8, aged 69, of massive cerebral hemorrhage.

Thorne, John Mairs ⊕ Pittsburgh; Jefferson Medical College of Philadelphia, 1886; associate professor emeritus of medicine at University of Pittsburgh School of Medicine; specialist certified by the American Board of Internal Medicine; past president of the Allegheny County Medical Society; fellow of the American College of Physicians; consulting physician, Presbyterian and Woman's hospital; died May 5, aged 87.

Tilt, LeRoy Wortendyke Jr. ⊕ Shelby, N. C.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1943; served during World War II; affiliated with Shelby Hospital; died in Kings Mountain May 12, aged 33, of Hodgkin's disease.

Tinkess, Arthur Lewis ⊕ LaFargeville, N. Y.; Queen's University Faculty of Medicine, Kingston, Ontaria, Canada, 1898; served during World War I; died in Greenwich, Conn., April 6, aged 80, of arteriosclerosis.

Van Winkle, Charlotte C., Taunton, Mass.; Johns Hopkins University School of Medicine, Baltimore, 1921; affiliated with Taunton State Hospital, where she died May 9, aged 59, of adenocarcinoma.

Wales, Reginald C., Lincoln, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1908; died in St. Petersburg, Fla., recently, aged 69, of carcinoma of the bladder.

Walker, Thomas Dick, Los Angeles; University of Tennessee Medical Department, Nashville, 1893; also an ordained Baptist clergyman; died April 13, aged 80, of intestinal hemorrhage and arteriosclerosis.

Whitehead, Vernon Erick, Blountsville, Ala.; University of Alabama School of Medicine, 1915; at one time on the faculty of his alma mater; died April 11, aged 61, of myocardial infarction and pulmonary emphysema.

Wickliffe, John Wakefield, West Union, S. C.; College of Physicians and Surgeons, Baltimore, 1888; University of the City of New York Medical Department, 1889; medical examiner for selective service during World Wars I and II; died April 23, aged 86, of cardiovascular renal disease.

Williams, Robert Bridgeforth, Huntsville, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1912; died in Tuscaloosa April 28, aged 67, of cerebral hemorrhage.

Williamson, Edwin Oliver ⊕ Gurley, Ala.; Chattanooga (Tenn.) Medical College, 1898; died recently, aged 79, of cerebral hemorrhage and arteriosclerosis.

Wollman, Cecilie Halberstadt, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1917; physician for the board of education; died May 7, aged 57, of coronary occlusion.

Woods, William Edward ⊕ Highland Park, Mich.; University of Toronto Faculty of Medicine, Toronto, Canada, 1920; affiliated with Florence Crittenton Hospital, Detroit, and Highland Park General Hospital, where he died April 23, aged 58, of intestinal obstruction.

Woodward, Erle B., Monrovia, Calif.; University of Michigan Homeopathic Medical School, Ann Arbor, 1899; died May 7, aged 76.

Wyland, Asa O. ⊕ Underwood, Iowa; State University of Iowa College of Medicine, Iowa City, 1889; died in Council Bluffs, April 12, aged 85, of intestinal obstruction.

Yarow, Fannie Hutoryansky, New York; New York Homeopathic Medical College and Hospital, New York, 1922; a physician with the Russian Army during World War I; died May 8, aged 65, of a cerebral accident.

Young, Harvey Wade, Red Bank, N. J.; New York University Medical College, New York, 1897; died in Riverview Hospital May 31, aged 79, of carcinomatosis.

GOVERNMENT SERVICES

SELECTIVE SERVICE SYSTEM

Lists for Inductions.—The National Advisory Committee to the Selective Service System has issued "Information Bulletin," vol. 3, no. 12, which reads as follows:

1. Selective Service lists for induction.—The National Advisory Committee has been sending to the state chairmen lists of special registrants who have been issued orders for induction. We are informed by the Selective Service System that subsequent to the receipt of these lists some chairmen are declaring men so listed as essential and requesting that they be deferred.

After an order for induction has been issued, a local board may not reopen the classification or consider a case anew except by direction from the state director. Neither can a local board postpone an induction except when there is an extreme emergency over which the registrant has had no control. Therefore, the only recourse at this time is to make representation to the state director and explain to him the changed circumstances that necessitate the declaration of essentiality.

When the registrant fills an essential position where replacement is not available every effort should be exerted to keep the local board fully advised at all times concerning essentiality of priority 1 physicians and priority 1 and 2 dentists; otherwise the local board will retain the special registrant in a class available for military service and hold him available to fill a call.

If a special registrant has been ordered for induction and the state director of Selective Service does not grant a request from a chairman to direct the local board to reopen and consider anew a classification and the chairman feels that it is imperative that the special registrant not enter the military service, representation should not be made to the armed force to which the registrant has been allocated for commission with request for delay in orders to active duty. Instead, a full report of the case should be made immediately to the National Advisory Committee for its consideration and such action as it deems appropriate with the National Headquarters of the Selective Service System.

2. Advice on priority 3 classifications.—In some state offices this has presented itself as a considerable work load. For the present, until further ground rules can be laid down, the youngest in the group should be considered first, working up through the ages as far as is feasible with personnel available and the necessary considerations to be given to cases of priority 1 and 2 reservists and registrants or other correspondence requiring immediate attention.

Essential in Community Practice.—Item one of "Information Bulletin," vol. 3, no. 8, of the National Advisory Committee to the Selective Service System, released July 8, reads as follows:

> The Illinois State Advisory Committee is using a plan which the National Advisory Committee desires all State Advisory Committees to use in connection with declaring physicians and dentists essential to community practice where it is considered to be necessary to do so. Such men are declared essential for six months with the understanding that the Chamber of Commerce, mayor or whatever organization has supported the essentiality must show evidence in writing at the end of six months as to their efforts to obtain someone to practice in that community; otherwise, the deferment will not be renewed. Such evidence would be in running ads in medical journals, contacting placement agencies, etc.

NAVY

Courses for Reserve Officers in Malariology and Insect Control.—Two week training courses for Volunteer Naval Reserve Medical, Medical Service, and Hospital Corps officers in malariology and insect control will convene at the Naval Air Station, Jacksonville, Fla., on the first and third Wednesdays of October, November, and December. The instruction will provide information on techniques to be employed in insect control and practical field experience, which is not readily available to these officers in their civilian occupation. Inactive Volunteer Reserve Medical, Medical Service, and Hospital Corps officers are encouraged to take advantage of the opportunity to attend these courses on active training duty orders in a pay status. Quotas have been allotted to the commandants of the first, third, fourth, sixth, and ninth Naval Districts and the Potomac River Naval Command. Eligible officers, who so desire, should submit requests to the commandant of their home naval district. Meals and sleeping quarters will be available at the Bachelor Officers' Quarters for those officers desiring such accommodations.

Personal.—The Surgeon General, Rear Adm. Lamont Pugh, and his executive assistant, Lieut. Commander Roy T. Brooks, left Washington, Aug. 1, 1952, for an extended tour of Naval medical facilities in Alaska, the Far East, and the European-Middle East areas. Last year Admiral Pugh visited Naval medical activities in the Pacific Ocean area, Japan, and Korea; and earlier this year he visited medical activities in the Caribbean area.——Rear Adm. Frederick C. Greaves, Medical Inspector General, and his executive assistant, Lieut. Commander Edwin W. White, left Washington, Aug. 10, on an 18 day inspection trip to the Pacific Northwest and Alaska.

VETERANS ADMINISTRATION

New GI Education and Training Bill.—Veterans with service anywhere in the world since the start of the Korean conflict, June 27, 1950, may now apply for up to 36 months' education and training under the new Korean GI Bill, Veterans Administration has announced. While in training, these veterans may receive an allowance from the government to cover part of their expenses. Application forms are available at all VA regional offices. Photostatic or certified copies of all discharges from the armed forces since June 27, 1950, must accompany the completed application. VA cannot pay educational allowances for training for any period that begins prior to Aug. 20, 1952.

VA advises veterans to take great care in planning and outlining the program of education and training in the second section of the form, since VA will not approve more than one change of program under any circumstances. Veterans should make sure that the school or business establishment is approved by the appropriate state agency for training under the Korean GI Bill (Public Law 550, 82nd Congress). The bill prohibits VA from approving a program of education or training leading to an educational, professional, or vocational objective for a veteran who is already qualified for such objective. It also prohibits the approval of avocational and recreational programs.

PUBLIC HEALTH SERVICE

Regular Corps Examination for Bacteriologists.—A competitive examination for appointment of bacteriologists to the Regular Corps of the United States Public Health Service will be held on Nov. 4-6 at a number of points throughout the United States. Applications must be received no later than Sept. 23, 1952. Appointments will be made in the grades of Assistant Scientist and Assistant Sanitarian (equivalent to Navy rank of Lieutenant, junior grade) and Senior Assistant Scientist and Senior Assistant Sanitarian (equivalent to Lieutenant). Appointments are permanent and provide opportunities for qualified bacteriologists to pursue their profession as a life career in research and public health activities. Candidates must be United States citizens and at least 21 years of age. Application forms may be obtained from the Chief, Division of Commissioned Officers, Public Health Service, Washington 25, D. C.

FOREIGN LETTERS

BRAZIL

New Use for BCG.—Drs. Luiz Batista and Norberto Belliboni presented a paper based on observations of a case of lupus erythematosus of fixed type, which had been developing for two years and recently showed progression of the lesions. They observed that there was tuberculin hypersensitivity on dilution of 1:1,000 (0.1 mg.), in consequence of which they submitted the patient to oral treatment with BCG. Before this therapy they had administered vitamin C and sodium salicylate to the patient for a short period, without any improvement of skin lesions. For desensitization purposes they used oral BCG in a dosage of 0.2 gm. per week. After a total dose of 1.2 gm. appreciable improvements were affected in the dermatological features, and after a total of 1.8 gm. the lesions had disappeared nearly completely, without signs of intolerance by the patient. After reviewing the literature on the oral use of BCG, Drs. Batista and Belliboni stressed the desensitizing and immunity strengthening action of this vaccine, suggesting this kind of treatment in all cases of dermatoses hypersensitive to tuberculin. They cited their experience in this field with erythema induratum, disseminatus, and discoid, and scrofuloderma, papulonecrotic tuberculids, Darier-Roussy's sarcoids, and erythema pernio.

Surgical Diseases of Esophagus and Cardia.—Dr. Fernando Paulino and his co-workers recently published their experiences in the treatment of diseases of the esophagus and cardia. They presented 66 cases with the following distribution: cicatricial stenosis 26, carcinoma 18, cardiospasm 9, diverticula 3, congenital stenosis 2, acute esophagitis 2, peptic ulcer 2, fibrosis of the cardia 2, and congenital atresia and stenosis from undetermined cause, 1 each. Regarding preoperative care, the authors emphasized the importance of the correction of blood volume and anemia, as well as the necessity of a liquid hypercaloric and hyperproteic diet and the use of local and general antibodies. After the operation, during the first days, intravenous feeding is in order, soon afterwards combined with oral nourishment, to give the patient the liquids, salts, proteins, calories, and vitamins that he needs in accordance with the body weight. Anesthesia by ether-oxygen is administered with intratracheal tube with cuff. With the experience acquired through over 150 thoracotomies performed by the same surgical team, the authors base the amount of blood to be replaced on the estimated amount of blood lost, according to hematocrit determinations. The quantity of blood necessary during an esophagectomy does not go beyond 1,500 cc. in the average case. Two cases of congenital deformities treated successfully through dilatation and one case of atresia in which a termino-terminal anastomosis of the esophagus was performed were shown. The authors pointed out the necessity for making maternity and pediatric clinics conscious of the possibilities in the treatment of congenital deformities of the esophagus, which should always be suspected when a newborn infant has excessive mucus in its throat, breathes poorly, or has attacks of cyanosis. Cicatricial stenosis and cardiospasm that do not present difficulties are generally treated through dilatation by different methods. Surgery is indicated only exceptionally in cases of cicatricial stenosis and in about 20% of the cases of cardiospasm. Cardioplasty was performed in five cases with good results. Three patients with diverticula were operated on, two of them had the pharyngoesophageal variety, and a one stage diverticulectomy was performed. In one supradiaphragmatic diverticulum a right transthoracic diverticulectomy was done. In all cases the results were good. The left transthoracic approach was used for esophagectomies, high or low according to the situation of the tumor. The anastomosis is done with interrupted sutures. Clamps are never used. Patients are fed orally from the second postoperative day, and from the sixth day a bland diet is given. The authors stressed the necessity for an early diagnosis of cancer of the esophagus, in order to improve the results obtained by surgery.

LUXEMBURG

Interallied Committee of Medical Reserve Officers.—The Sixth Study Session of the Interallied Committee of Medical Reserve Officers, which includes the medical reserve officers of the Atlantic Pact countries, was held in Luxemburg under the presidency of Dr. Kremer of the Netherlands. The committee is composed of representatives of the federative unions of reserve physicians of the various countries, and in the course of the opening session Major Felton, M.D., Chief of the Health Service of the Army of Luxemburg, announced the formation of an association of reserve physicians of Luxemburg.

One of the aims of the committee is to clarify major questions in the treatment of wartime emergencies. The session took up the question of the treatment of burns. Dr. Kummer, Netherlands delegate, outlined the following scheme for the initial treatment. A burn is sterile and must not be infected. Clothing should not be removed from the burned person at the place where the injury occurred, because proper dressing of the injury is then impossible. A sterile dressing should be placed over open wounds, without causing pressure from the dressing. If the injury exceeds 15% of the body surface, the patient should be given antishock treatment, consisting of plasma, sodium chloride solutions and sodium citrate solutions by mouth, an antitetanus injection, morphine, and treatment with penicillin.

At a first-aid station antishock treatment should be given according to the seriousness of the case. If possible, the patient should be evacuated rapidly while penicillin therapy is continued; the urine should be examined. If the patient is kept at the first-aid station, results of the antishock treatment should be awaited before beginning local treatment. The patient should be undressed, placed on sterile compresses, and treated for relief of pain with morphine or light anesthesia with ether. Surgical débridement of the wound and ablation of the necrosed tissues should be carried out; dressing with sterile compresses, toes and fingers separated, should be applied. Immobilizing plaster casts permitting freedom of movement for toes and fingers are necessary. Grafts should not be applied at the first-aid station. Hydration should be maintained by drinks in adequate quantities; in the ensuing period of from 2 to 10 days, the patient should be evacuated to a specialized hospital, sending along a detailed report of the treatment given. Colonel Vandermeiren, M.D., of the Belgian Army, dealt with the problem in the capacity of a military medical expert and a sanitary tactician. He emphasized the importance of the standardization of the first aid to be given and the necessity of evacuating the patient to a sanitary establishment where he can be kept, because rest plays a large part in the efficacy of therapeutic measures. He insisted on the value of systematic organization of the examination and treatment.

Dr. Koch (Amsterdam) showed a series of slides illustrating the operative techniques to be used in correcting facial cicatrices. Professor Menegaux (Paris) reviewed the various complications that may be observed in the course of cicatrization, such as hypoproteinemia and death, and discussed the treatment of cicatrices, dwelling in particular on certain points of technique concerning the hand and fingers. Functional re-education of the burned patients should be undertaken as soon as possible.

Colonel Tugan (Turkey) advocated the slow injection of concentrated plasma in the treatment of hypoproteinemia. Professor Cinerei (Italy) emphasized the economy that can be secured in the use of plasma by replacing it in part with alkaline solutions by mouth and especially by the use of modified horse plasma. He pointed out the useful effects of subcutaneous oxygen therapy and the use of arterial injections of penicillin-novocaine in burns of the members as well as the ease of compress dressing with gelatin sponges.

Following these expositions, General Glorieux, M.D., Belgian Army, summarized all the present information in the form of a syllabus, which was adopted by the committee and can be used as an instruction manual for all physicians.

The items in these letters are contributed by regular correspondents in the various foreign countries.

PARIS

International Youth Center.—Under the direction of Prof. R. Debré, member of the National Academy of Medicine, the activities of the International Youth Center are progressing. During 1952 two exhibitions intended for public education took place: "The First Year of Life" and "The Hazards of Tuberculosis and the Child." Social investigations on various questions concerning the child's welfare are undertaken under the name of "Mégève Colloquies." Other investigations on the lack of maternal care are simultaneously pursued in Paris and London. An important documentation center and library with microfilms and photocopies has been organized at the Longchamp Center. The center publishes a monthly journal, *Le Courrier,* and is preparing a quarterly review, *Etude néo-natale.*

The scientific works performed by the center's pilot station are pursued in the fields of pertussis and BCG vaccination. On Feb. 18, 1952, a conference of the study group for antituberculous vaccination was held at the Longchamp Castle. It was attended by several French and foreign personages, among whom were H. J. Ustvett (Oslo), C. Palmer, T. H. Madsen, and Miss L. Edwards (all from Copenhagen), and D. Thomson and J. Fanconi (Switzerland). Since 1950, the pilot station has undertaken a series of laboratory and clinical examinations of the technique of BCG vaccination. Interest was shown in the Trambusti test, performed with a needle with automatic penetration as a unique method for mass vaccinations. The method of intradermal injection of dead bacilli gave very severe local reactions at the pilot ation, which led them to discard it. It is believed that a scarifica n through a drop of BCG killed at 100 C would avoid this inconvenience. The systematic radiological examinations of children vaccinated at the Lille Pasteur Institute permitted observation in children of hilar-pulmonary images. A device is under study that would make it possible to obtain allergy of sufficient degree and duration, together with a minimum of ganglial lymph node complications. The problem is to find the precise doses to be given according to age as well as the proper time and dose for revaccinations. In the course of the discussion, C. Palmer reported that the observations at Copenhagen indicate that a very noticeable reduction of the dose of vaccine does not modify appreciably the rate of the postvaccinal allergy. He also stressed the effect that exposition to light exerts on the vaccine by diminishing the number of living germs it contains, a possible cause of discordance between the various results obtained. Professor Sarrouy (Algeria), J. Gaud (Morocco), and J. Goujou (Tunisia) stated that for two years the number of vaccinated subjects was 1,007,000 for Morocco, 264,000 for Tunisia, and 295,000 for Algeria. A practical question, which has not yet been resolved, is the necessity of associating smallpox vaccination with BCG.

Scientific Program.—The pilot station will continue to deal with the following questions: (1) systematic follow-up of subjects previously vaccinated with BCG, (2) the relation between the natural disposition to develop a strong allergy (which appears to be partly hereditary) and the resistance or sensitivity to tuberculous immunity existing in certain families, a question that will be studied in Paris and certain large towns of North Africa, (3) the reactions of mediastinal glands occurring in vaccinated persons who will submit to monthly systematic radiological controls from the third to the eighth month following vaccination, and (4) comparative study of BCG vaccine of various origins, dry vaccines and vaccines originating from cultures maintained in bile containing medium.

The program, in the process of being carried out, was presented by M. Tubiana: (1) to study the reaction of organisms as regards BCG and BK, both tagged by radioactive isotopes, (2) to find out in guinea pigs whether the resistance to superinfection only persists as long as allergy exists, (3) to study the effects exerted by injections of BCG in rabbits treated with corticotropin (ACTH) or cortisone, (4) to search for the presence of tuberculous antibodies by the reaction of hemagglutination, and (5) to try to sensitize healthy animals by the injection of tuberculin fixed on human red blood cells.

To coordinate scientific work, it was decided that organizations such as the Medical Research Council (of Great Britain) and the pilot station will come to an agreement on the repartition of the subjects to be studied.

SWEDEN

Birth Rate and Abortion Problems.—As recently pointed out by Prof. Sven Brisman, there are few countries in the world, if any, with a more widely fluctuating birth rate than Sweden's. The remarkably low birth rate in the 1930's led to a series of remedial measures by the government. There was a low record in 1935, with only 86,000 live births, and for the next few years Sweden's birth rate was the lowest in its history. World War II suddenly sent the birth rate up, and in 1945 there were as many as 135,000 live births. Since this year there has been a fall of the birth rate, and in 1951 the number of live births was only 110,000.

This remarkable fall in the Swedish birth rate gives added importance to the high legal abortion rate. In 1950 in Stockholm there were 11,587 live births, and in the same year and city 1,790 legal abortions were induced. More than 30% of the 6,000 legal abortions induced in 1950 in the whole of the country were in Stockholm. These legal abortions are being scrutinized, and reference has already been made in THE JOURNAL (**147:**1775 [Dec. 29] 1951) to an investigation into the psychological reactions of the women for whom abortions have been induced. A more recent investigation has now been undertaken by a psychiatrist, Dr. Martin Ekblad, who has had personal conversations with women for whom abortion had been induced at the Sabbatsberg Hospital. They were questioned directly after the operation while still in the hospital and also after a considerable interval. One-third of the women for whom legal abortion was undertaken became pregnant again within a short time, 20% of them within 12 months of the abortion. Hence, Dr. Ekblad concluded that it is impossible to solve the abortion problem before the problem of teaching the prevention of conception has been successfully solved. Regrets and a sense of guilt were expressed by 21% of the women he questioned, whereas 79% expressed satisfaction with, and gratitude for, the operation they had undergone.

Vanishing Tuberculosis Mortality Under the Age of 50.—The counties of Uppsala and Södermanland have lately given statistical information about the age distribution of persons who die of tuberculosis. Prof. Erik Hedvall and Dr. Olle Hillerdal noted that practically all the tuberculosis deaths in 1951 in the town of Uppsala occurred in persons over the age of 50. Thereupon they investigated the age distribution of all the tuberculosis deaths in the county of Uppsala between 1943 and 1951. In 1943 there were 48 tuberculosis deaths in persons under the age of 50, 15 such deaths in those between the ages of 50 and 70, and 5 such deaths in those over the age of 70. In 1951 there were only 3 tuberculosis deaths in persons under the age of 50, 8 such deaths in those between the ages of 50 and 70, and 11 such deaths in those over 70. In other words, the fall in the tuberculosis mortality in the period under review depended almost entirely on the age group 0-50 years. Professor Hedvall and Dr. Hillerdal discuss five alternative or complementary explanations for this state of affairs; it may be due to the ever extending BCG vaccination, diminished infection, modern chemotherapeutic and antibiotic treatment, advances in chest surgery, or the change in the age distribution of the population with a relative increase in the number of elderly persons dying of tuberculosis. With regard to the third point, it should be noted that extensive use was not made of modern chemotherapeutic and antibiotic treatment for tuberculosis till 1948. This treatment has undoubtedly helped to reduce the tuberculosis mortality, but its fall was already demonstrable in 1947. With regard to the fourth point, instructive light is thrown on it by Dr. P. Rudström, who quoted statistics published by the Swedish National Association Against Tuberculosis. They show that in 1945 the number of patients with pulmonary tuberculosis operated on in Sweden was 719. In 1950 the corresponding figure was 1,616. In a survey of 300 patients operated on in a surgical hospital in Uppsala during the period 1948-1951, Dr. Rudström has pointed out that there were only 8 fatalities among them. In an earlier period, 1929-1932, the operation mortality for this hospital was as high as 23%. Since then it has fallen steadily, and at the present time patients as well as physicians in Sweden are often keen to extend the indications for operative treatment.

TURKEY

Isonicotinic Acid Hydrazid Therapy in Tuberculosis of the Lung.—Phthisiologist Dr. Tevfik Ismail Gökçe, medical director of the 530 bed Istanbul-Heybeliada Tuberculosis Sanatorium, presented a report to the Istanbul Tuberculosis Society concerning the results obtained in 10 patients who were given "nydrazid" (Squibb & Sons) therapy, in 12 patients given "nicotibin" (Lepetit Laboratory), and in 9 patients given "rimifon" therapy (Hoffmann-La Roche Inc.) during last March.

The selected patients had extensive active tuberculosis with a profusion of Koch bacilli. The majority of the patients had caverns in both lungs and were febrile. They failed to respond to streptomycin and other antibiotics. Of the 31 patients 20 were women and 11 were men. Twenty-five patients were 18 to 30 years old, and six patients were 30 to 60 years old. In 25 patients both lungs were affected, and the majority had exudative forms, in 6 patients one lung was affected, 17 patients had caverns in both lungs, and 10 patients had caverns in one lung. In six patients pneumothorax had been of no avail. Ten patients had pneumoperitonitis, of whom two patients had hydropneumothorax in one lung, one patient in both lungs, and one had pneumothorax in one lung and extrapleural pyopneumothorax in the other lung; one patient had pyopneumothorax and an external fistula as the result of pneumonectomy; one patient had tuberculous enteritis; and one patient had tuberculous laryngitis as a complication.

Of 31 patients 28 had previously been given streptomycin therapy; of these, 19 patients were given streptomycin and *p*-aminosalicylic acid therapy and 1 patient was given streptomycin, *p*-aminosalicylic acid, and amithiozone. Seven patients were given 10 to 30 gm. of streptomycin, nine patients 31 to 60 gm., six patients 61 to 90 gm., and six patients 90 to 150 gm.; streptomycin resistance developed in eight of these patients.

Before the new therapy was begun, all patients were given a thorough check-up, the sputum was reexamined, blood counts, formula, and sedimentation rate redetermined, urinalyses made, kidney and liver function investigated, and new roentgenograms taken. These investigations were repeated every 10 days during the therapy and at its termination. The patients were given a 50 mg. tablet of isonicotinic acid hydrazid four times daily and a 100 mg. tablet twice daily, an average of 3 to 5 mg. per kilogram of body weight. At the initiation of the therapy 1 of the 31 patients was subfebrile and 24 patients were febrile; of these 11 patients had been so for 12 months, 6 patients for 3 months, and the other patients for 4 to 6 weeks. In 19 of the 24 patients the temperature subsided, and in 5 patients it continued. In 27 patients coughing decreased, and in 4 patients it remained unchanged; in 24 patients the amount of sputum decreased, and it remained unchanged in 7 patients. At the initiation of the therapy, the sputum of the majority of the patients revealed a profusion of tuberculosis bacilli examined by direct method. After a month of therapy, the sputum of 27 of 29 patients had negative results by direct method; the result was positive in 18 patients by homogenization method and negative in 9 patients. These nine patients, or 31%, also had negative reactions by culture method.

The general conditions of the patients were markedly improved. In patients who had previously steadily lost weight, the appetite improved and was followed by an immediate gain in weight; two patients developed a ravenous appetite. Of 31 patients, 3 lost weight during the therapy and 28 gained weight. Of the latter, 4 patients gained 200 gm. to 1 kg.; 8, 1 to 2 kg.; 9, 2 to 3 kg.; 5, 3 to 4 kg.; 2, 4 to 5 kg.; and 1, 7 kg. 700 gm. during the one month of therapy. The average gain was 2.5 kg. per patient. Roentgenographic evidence showed no change in 24 patients. There was improvement of variable degrees in seven patients, as evidenced by regression of exudative processes, reduction in the size of caverns, and the absence of cavities by direct radiography. These improvements occurred in patients with new fresh lesions. In one patient the radiological symptoms increased, and new nodules and lesions developed. An exudate developed in the patient with pneumothorax. In the patient with tuberculous enteritis as a complication the diarrhea subsided. In the patient with tuberculous laryngitis as a complication of 14 months standing the infiltration in the arytenoid region and in the left plica vocalis subsided after a week's therapy, difficulty in swallowing disappeared, the voice began to regain its natural tone, and laryngitis had completely disappeared at the end of the month.

Except in one patient, undesired and toxic reactions indicating discontinuation of the therapy did not occur. Reflexes increased in five patients, two of whom had vertigo; diarrhea developed in three patients and eosinophilia in two. One patient had a rise in blood pressure, and one had a decrease. In one patient the sense of hearing was diminished; one patient had skin eruptions and itching, and one patient had vertigo. All these side-effects subsided after a few days. In the patient who had an external fistula as a result of pneumonectomy and also had amyloid degeneration the albumin in the urine increased from 6 gm. per liter to 9 gm. and the edema increased; the therapy was discontinued.

Terramycin Therapy in Trachoma.—In *Eye Clinic,* an Istanbul periodical, ophthalmologist Dr. Izzet Bilger has published his observations on the effectiveness of terramycin on trachoma on 700 patients in the Adana Trachoma Hospital and Dispensary. Terramycin hydrochloride was administered per os, 250 mg. in capsules, 0.1% and 0.5% ointment, and 0.5% solution of eye wash. Of 38 patients with acute trachoma 27 patients recovered after 3 to 6 weeks and 11 patients after 5 to 10 days. Twenty-seven patients who were given terramycin orally, ointment, and eye wash recovered after 20 days, but slight gastrointestinal irritation developed. Patients with chronic trachoma needed from two to three months therapy for complete recovery, and to prevent a relapse the therapy was continued for another month. A combination of chemotherapy and surgical intervention in chronic and complicated cases accelerated recovery.

From a special school for children with trachoma, 640 children who had chronic trachoma were selected and divided into three groups. The patients in group one were given terramycin only, in group two terramycin and chemotherapy, and in group three terramycin, chemotherapy, and surgical treatment. In almost all patients bleeding and suppuration decreased in from one to two weeks, and after from two to six weeks 20% of the patients had recovered. After 12 weeks 80% recovered, but therapy was continued for another month after recovery. In seven patients the symptoms increased at first; two of these patients improved as treatment was continued, but in the other five patients there was no improvement even after 12 weeks' treatment. Two of 34 trachoma patients with acute pannus and corneal complications were given 2 gm. of terramycin for three days; acute symptoms subsided on the fourth and fifth day. Twenty-eight patients were given ointment and eye wash therapy. Pain and photophobia subsided after 24 hours, cornea complications subsided after 6 days, and in most of these patients vision improved. Four patients with pannus hypertrophy recovered in from 10 to 15 days.

Five of 13 hospital patients, aged 13 to 62, had trachoma and corneal complications, 1 had trachoma and acute flux, 1 had florid trachoma, the other 6 had corneal ulcers and infiltration, and 1 had in addition follicular conjunctivitis. With the exception of one patient subjective symptoms began to subside after from 24 to 48 hours after the initial treatment, and in from 3 to 5 days there was marked improvement. Of six dispensary patients that were followed up, three children, 1, 3, and 4 years old, had acute trachoma and severe ophthalmia in both eyes; acute trachoma in two patients, 17 and 28 years old, was complicated by follicular conjunctivitis and flux; and a 50-year-old patient had advanced trachoma and flux. Four of these six patients were given terramycin ointment for one eye and eye wash for the other eye; the patients that were given ointment recovered sooner. With the exception of one patient with hypopyon corneal complication, the hospital patients recovered in from 9 to 24 days. Dispensary patients recovered in from 3 to 5 days. In 11 dispensary patients with trachoma complicated by severe ophthalmia very good results were obtained with terramycin ointment therapy. Terramycin was well tolerated by all patients.

Turkish Red Crescent's Health Program.—To further the health of the nation, the Turkish Red Crescent Society has set aside from its budget 4 million Turkish pounds for the year 1952. According to Prof. Ekrem Hayri Üstündag, the minister of health and social assistance, who also is a member of the society's central committee, 300,000 pounds are to be spent for the construction of a 100 bed preventorium-sanatorium for university students, as an annex to the Istanbul-Erenköy tuberculosis sanatorium, 400,000 pounds for the construction of a 100 bed maternity hospital as an annex to the Izmir Children's Hospital, 300,000 pounds for the construction of a 100 bed tuberculosis hospital in Adana, 400,000 pounds for the construction of a 50 bed hospital in the town of Mus, population 45,349, and the eastern province near Lake Van, and 200,000 pounds for establishment of each health center providing medical care and free medicaments in nine eastern frontier districts. There will be 450,000 pounds spent for the construction of a cancer research institute in Ankara, and 320,000 pounds are to be spent for the purchase of 12 mobile units for operation in the eastern and southeastern trachoma campaign areas. The Red Crescent will participate in the trachoma campaign by supplying terramycin and other antibiotics. There are still 250,000 persons who have trachoma. When these constructions have been completed, the Turkish Red Crescent Society will turn them over to the government for administration by the ministry of health and social assistance.

CORRESPONDENCE

CHRONIC URETHRITIS IN GIRLS

To the Editor:—I should like to take issue with Dr. Hodges' statement in THE JOURNAL, June 21, 1952, in his article "Chronic Urethritis in Girls." On page 756, he states, "One does not need the services of a urologist to diagnose the ordinary case of chronic posterior urethritis. The history of recurring episodes of urinary frequency, enuresis, fever, and pyuria is highly suggestive."

It is the opinion of this urologist that recurring urinary frequency, fever, and pyuria in a child are not suggestive of urethritis but of upper urinary tract infection, and a complete [illegible]cal study is strongly indicated.

[illegible]e were to heed Dr. Hodges' advice, many a case of hydronephrosis or other types of renal disease would progress to serious proportions before necessary steps for proper therapy would be taken.

REACTIONS TO ISONIAZID AND IPRONIAZID

To the Editor:—Isoniazid (isonicotinic acid hydrazide) and iproniazid (1-isonicotinyl-2-isopropylhydrazine) are being given to many patients with tuberculosis throughout the United States and in many other countries. Toxic reactions to both drugs have been reported and, undoubtedly, more will occur. However, it is unlikely that any single investigator will observe enough of these toxic reactions in the next few months to warrant publication. The Committee on Therapy of the American Trudeau Society is anxious to collect reports of these toxic reactions, so that a consolidated report can be made available to the medical profession as soon as possible.

Any physician who is willing to submit such reports to the committee is asked to send a brief case report to the Committee on Therapy, American Trudeau Society, in care of Dr. D. T. Carr, 102-110 Second Avenue Southwest, Rochester, Minn. The report should include the patient's name or initials, his age, sex, race, diagnosis, weight, the drug administered and its dosage, the duration of treatment, and a list of other drugs being given at the same time. The toxic reaction should be described fully together with information as to its recurrence if the same drug was given later.

Copies of the consolidated report will be sent to all contributors, but will not be published in such a way so as to preclude individual publications.

GRAVITY RESISTING ABILITY OF THE CIRCULATION

To the Editor:—Some new drugs for the treatment of high blood pressure cause a decrease in the pressure on standing to the point of dizziness and fainting, i. e., orthostatic hypotension. This is to be avoided. The recommendation of makers of such drugs for study and selection of cases is good. It is suggested that a method for estimating the gravity resisting ability of the circulation, i. e., contra-orthostatic-hypotension ability, introduced many years ago, may be utilized for this purpose. This test consists in taking both the blood pressure and the pulse rates with the patient standing and lying.

The fall of the blood pressure and the rise of the pulse rates on standing indicate weakness. This was reported in 1904; it was picked up by Schneider at Mineola in 1916, and the two items were included in his six-point test. This test will show the presence and degree of orthostatic hypotension. It is not generally known that blood pressure can fall from 30 to 100 points on standing, and that a man can and sometimes does have high blood pressure in bed, and low blood pressure standing. The prognosis is far better for the man who has no postural fall in pressure, as the records show.

Thus we have a method of discovering and recording the gravity resistance ability of the individual. Although hitherto somewhat neglected, this method will give a clue to the efficiency of the splanchnic vasotone. This test may aid not only in therapy and clinical management but also in better understanding of the disease and, what is more, of the patient.

FOREIGN GRADUATES AS INTERNS

To the Editor:—During the past year, with the cooperation of the Office of the High Commissioner of Germany, the State Department, and cooperation of doctors and hospitals in New Jersey, sixty-five carefully screened recent graduates of foreign medical schools have been placed in A. M. A.-approved rotating internships in New Jersey. Upon the completion of the internship they must return to their homeland.

Word of mouth reports on this experiment have apparently gotten around fairly well in medical centers abroad so that almost daily we receive applications for residencies here in America. Only today we received a request from a surgeon in India who has a master of science degree in surgery from the University of Michigan asking us to attempt to place him as a resident in surgery at a second year level. A member of the United Nations Permanent Secretariat from India recently urged us to interest ourselves in some of his fellow countrymen whom he would personally guarantee as going back into excellent teaching positions where they could have a definite impact on the political, cultural, and medical conscience of India.

If any hospitals or doctors are interested in this experiment and have any approved residencies open, we will be glad to pursue these opportunities further.

COUNCIL ON MEDICAL SERVICE

This is the third in a series of studies made by the Committee on Indigent Care of the Council on Medical Service concerning local plans for medical care of the indigent. A general introduction to the series and the first of the Committee's studies (Erie County, New York) appeared in the May 10, 1952, issue of The Journal, *pages 188-191. The second study (Madison, Wisconsin) appeared in the July 26, 1952, issue, pages 1247-1249.*

MEDICAL CARE FOR THE INDIGENT IN NEWARK, NEW JERSEY

This report concerns the medical care available for indigent residents of Newark in Essex County, New Jersey. The county has approximately 905,000 residents, of whom 439,000 live in Newark, the state's largest city. Newark is highly urban and industrialized. It is located in the eastern part of New Jersey, within the New York City metropolitan area.

ELIGIBLE POPULATION

General assistance programs are administered by Newark itself, while the public assistance programs are county-wide in scope. During the year 1950, approximately 13,150 persons in Newark, or about 3% of the city's population, received aid under the city programs. About 8,730 residents, or about 1% of the county population, received aid from Essex County public assistance agencies. The number of city residents receiving public assistance aid is not available; however, if the percentage of the population receiving aid is assumed to be the same for city and county, a total of 4% of the city's residents or approximately 17,692 persons received aid under the combined programs. Table 1 shows the distribution of the recipients of aid among the various assistance programs. Because of the differences in administration and population covered, general assistance and public assistance programs will be discussed separately.

Table 1.—*Distribution * of the Recipients of Aid Among the Assistance Programs, 1950*

General Assistance (Newark residents only)	
Indigent (mean of relief rolls for year)	8,704
Medically indigent (cases treated)	4,446
Public Assistance (whole of Essex County)	
Old Age Assistance	5,000
Aid to Blind	209
Child Welfare (1,517 families)	3,521

* No allowances have been made for duplication of coverage.

GENERAL ASSISTANCE

Administration.—In Newark, medical care for the indigent (those actually on relief rolls) is provided through the department of public welfare and for the medically indigent (persons able to provide the basic necessities for their own subsistence but unable to pay for medical care) through the Newark Health Department. Both departments are part of the city's division of public affairs, headed by the director of public affairs, who is one of the five city commissioners. Both departments report to this director, and all budgets and emergency appropriations must be approved by him and by other city commissioners.

The director of welfare and the health officer exercise immediate supervision of their respective departments. However, policies and procedures of the welfare department are subject to the approval of the local assistance board, appointed by the director of public affairs. The welfare department is under the general supervision of the New Jersey State Department of Institutions and Agencies and submits reports to this body as well as to the division of public affairs. Each department is in charge of planning, determination of eligibility, authorization of treatment, special procedures, and review for its own medical program.

The welfare department maintains a central clearance division, which provides information concerning eligibility to the city hospital, the medical social service department, the health department, and the Medical Service Administration (the agency through which payments are made to private physicians). The two latter agencies are continually advised of status changes as they affect the clients' eligibility for services provided. All clients applying for medical assistance are cleared through this division, and any assistance given by the county welfare board to Newark residents is also noted and passed on to the investigators concerned.

Indigent cases are reviewed every two weeks to determine continuing eligibility, unless the client is permanently disabled. These cases are reviewed monthly by the department's case workers. The health department has a small staff of medical social workers who check on the medically indigent patient's ability to pay. New patients who are not on the welfare department's relief rolls are personally interviewed; in addition, spot-check home visits are made, especially for home care by physicians. If the physician suggests that the patient is able to pay, the department investigates further and bills those clients who are ineligible for free care.

Bills from private physicians are examined carefully; if a charge seems exorbitant, payment is withheld and the bill is reviewed by the Essex County Medical Society. Indigent patients may appeal to the state welfare agency; medically indigent patients must appeal to the Newark Health Department.

Services Available.—Indigent and medically indigent patients are eligible for the same medical care, through the same facilities. Patients may receive home care from a private physician of their choice, provided the physician has agreed to work with the program. However, since ambulatory patients are generally treated at the health department clinic, the free choice system functions primarily for home visits. The clinic provides all special medical services as authorized by the department from which the patient receives aid.

Other special services are provided by 24 neighborhood clinics, used for well-baby stations, tuberculosis examinations, and prenatal and dental clinics; nine neighborhood dental clinics for treating both adults and children; and a main dental clinic, which provides treatment for children three days a week and adults two days. The health department maintains an allergy clinic, to which patients are referred from the dispensary clinics and from other allergy clinics when they cannot afford the usual clinic fees. Neuropsychiatric treatment is available at the city dispensary.

The welfare department also maintains a medical center, which does not provide treatment but was initiated so that case workers could maintain current adequate knowledge of the medical status of each client. Cases are discussed individually at weekly conferences between the medical director and the case supervisors. The medical staff is composed of a nurse and four physicians loaned by the health department and one psychiatrist; non-medical personnel are provided by the welfare department. Authorizations for special medical service for welfare clients must be approved by this center.

Patients may receive treatment at the outpatient departments of the private hospitals at their own expense, at a fee of 50¢ to $1.00 per visit. Hospitalization, when recommended by a physician, is provided at Newark's City Hospital. If the city hospital has no vacancies, patients are sent to private hospitals in the city. The hospitalized patient does not have free choice of physician. Clients may receive home nursing care from the visiting nurse association or convalescent care from Newark nursing homes, when recommended by a physician.

Prescriptions are filled at the health department pharmacy. When this dispensary is closed, emergency prescriptions may be filled at private pharmacies at the authorizing department's expense. Medicines recommended by the physician and not available through the city dispensary are purchased by the department involved. When recommended by physicians, special diets are provided for the ill through an accredited dietitian who determines the food needs of the patient. Hospital surgical appliances, orthopedic shoes, eyeglasses, and other appliances are provided when necessary for the health or rehabilitation of are paid for prescriptions filled for clients of the programs, although physicians are requested to avoid prescribing expensive proprietary drugs unless necessary for treatment. In the child welfare program, the pharmacist may either bill the board of child welfare directly or charge the mother or foster mother, who will then be reimbursed by the board.

Costs and Financial Support.—Funds for all programs are provided by state and county appropriations and by federal subsidy, except that no federal funds are received for the care of children who are wards of the state. New Jersey supplies 87% of the funds for the old age assistance program; in the Child Welfare programs state and county pay an equal share of the cost.

Hospitalization as a part of the New Jersey old age assistance program is provided only in Essex and Gloucester Counties, where the boards of freeholders make appropriations directly to the county welfare board for such service. In the other counties, old age assistance patients are hospitalized through general assistance programs, as are aid to the blind clients in Essex County. Dependent children are hospitalized through board of child welfare funds.

Appropriations are made annually and emergency appropriations can be made if insufficient funds are provided. The county welfare board, in addition, has the right to insure anything of value belonging to an old age assistance client and put the insurance policy into trust. This money can be used for burial expenses and for partial reimbursement of the program. Detailed cost figures are available for the old age assistance program only. The expenditures for this program in 1950 are shown in the following tabulation:

Physicians	$ 66,622.90
Visiting Nurse Association	7,194.68
Pharmacists	64,412.99
Clinics	12,688.01
Other medical expenses (dental, eye, chiropody, etc.)	15,477.81
Total medical expenses	$167,196.39
Hospital (may include convalescent care)	235,000.00
Total cost	$402,196.39

The aid to the blind program had a monthly medical expense of approximately $249.73, or $2,973.00 per year. The child welfare program does not have cost figures available for Essex County.

Using these figures as a basis, the annual cost of physician's care per person eligible for old age assistance was $13.32 in 1950 and the total cost was $80.44 per person. Annual medical expenses of aid to the blind per person eligible was $14.22. Since these figures refer to those eligible for care rather than to the actual number of patients treated, no analysis of cost per case is possible.

Medical Society Relationship.—The Medical Society of New Jersey is studying methods of facilitating the payment of private physicians for care to old age assistance clients. The state has requested the society to develop some plan, similar to the Medical Service Administration, which will enable the state to reduce the bookkeeping and supervision required in making separate payments to individual physicians.

The Essex County Medical Society has entered into active cooperation with all three programs. It attempts to stimulate physician participation and acts as a board of review for all bills submitted by physicians and for complaints concerning alleged abuses by physicians.

The county society has also entered into an agreement with the state board of child welfare, through the society's child welfare advisory committee, to facilitate the care of dependent children. Before 1948, the state negotiated with the individual physicians who provided this care; beginning with that year, the society has provided and kept up to date a list of all members who agree to treat child welfare patients. The list is distributed by the district office to all child welfare clients. The society's child welfare committee also acts as an advisory or liaison committee to the state board; it reviews bills, hears complaints against physicians, and provides professional consultation and advice at the request of the district supervisor of the program.

SUMMARY

Indigent and medically indigent residents of Newark receive medical care through a variety of programs and a variety of agencies. Medical care for general assistance clients is provided under the supervision of city departments, while public assistance is provided through county-wide programs by county offices under state supervision. Benefits, payments, and method of payment differ somewhat from one program to another but, in general, much the same services are provided in all programs.

No single agency is responsible for over-all supervision of medical care in Newark, but the central clearance division of the Newark Welfare Department maintains records on all recipients of medical aid, whether from city or county offices, and notifies city departments of the status of each client. In the absence of a unified program, this office serves to provide some coordination of aid for city residents.

The major point of interest in the Newark plan is the Medical Service Administration, which serves as an intermediary between the private physician and the departments providing general assistance. This agency makes possible free choice of physicians for home care, with a reasonable reimbursement for the physician, yet keeps control of this care firmly in the hands of the medical profession. The agency has provisions for the review of bills and for hearing complaints, whether from the physician or the welfare authorities. It keeps involvement of the physicians in red tape to a minimum.

The Medical Service Administration is designed to serve as a state-wide agency, though at present it is operating only in the Newark area. The state old age assistance authorities have suggested to the state medical society that a similar plan be formulated to handle payments for care of the aged.

An important factor in providing proper care in Newark is the guarantee that a physician will receive payment for his first visit to a patient, whether or not the patient is eligible for free care. This rule assures immediate treatment of emergency cases without the delay necessary to check the welfare status of the patient.

Provision is made for utilizing all types of medical facilities in the city, although in the general assistance and child welfare plans primary emphasis is placed on use of the City Hospital and Dispensary. The provision for convalescent care of old age assistance patients in New York nursing homes when Essex County homes have no vacancies is particularly noteworthy.

The Essex County Medical Society, through advisory and liaison committees, supervises the quality of medical care and reviews bills to determine whether fees are fair to physicians and to the welfare programs. Participation in the programs is, however, uneven. All physicians are willing to treat old age assistance clients, while only 17% of the county's physicians have agreed to handle child welfare cases, and only 7% of Newark's physicians handle the city's general assistance cases.

The program as a whole has an obvious disadvantage in its lack of unified administration. General assistance is provided at a city level, through two city agencies; public assistance is provided at a county level, through two county agencies and the state authorities. At least three separate investigating staffs are maintained to determine eligibility; authorization for care, depending on the program, may be at a city, county, or state level, as is payment of bills. The Medical Service Administration, organized for state-wide service, is used only in Newark and only for general assistance payments, although it appears to be an efficient agency to handle payments to physicians for all programs.

There also appears to be some confusion in the benefits offered by the various programs. One program allows the use of private clinics only, another allows the use of both private clinics and the Newark City Dispensary, while another allows private clinic care only at the patient's own expense. Some patients will find it necessary to receive aid from both general and public assistance programs in order to obtain complete medical care.

In general, however, despite the multiplicity of agencies, the indigent resident of Newark seems to have available all medical services necessary for treatment and rehabilitation, with a minimum of delay between request for care and first treatment.

COUNCIL ON NATIONAL EMERGENCY MEDICAL SERVICE

The Council on National Emergency Medical Service has authorized publication of the following statement.

C. Joseph Stetler, *Secretary.*

WILLIAM L. WILSON PROMOTED

On July 24, 1952, Col. William L. Wilson, Assistant Administrator, Federal Civil Defense Administration, was promoted to the rank of brigadier general.

In his position as head of the Health and Welfare Division of the Federal Civil Defense Administration, General Wilson has, for more than a year, worked diligently at the difficult task of educating the country and the medical profession in the medical aspects of civil defense. His technical knowledge, his personal enthusiasm for his work, and his cooperation with the Council on National Emergency Medical Service have been largely responsible for the encouraging progress that has been made in medical civil defense preparedness throughout the country.

On behalf of the medical profession, the Council on National Emergency Medical Service would like to congratulate General Wilson on his promotion and express the hope that the Council and the profession will continue to have the benefit of his knowledge and his efforts in medical civil defense work.

MEDICAL MOTION PICTURES

Rheumatoid Arthritis of the Spine: (PMF 5163) 16 mm., black and white, sound, showing time 34 minutes. Produced in 1951 by the U. S. Army. Procurable on loan from the Area Surgeon of the Army Area in which the request originates.

This film begins with a discussion of the various terms used in describing rheumatoid arthritis and then describes in excellent fashion, by means of animated diagrams, the pathological lesions that exist. This is followed by good pictures of the roentgenogram findings, and then the physical findings are demonstrated. Finally the management of the type that begins with an acute onset is described carefully and satisfactorily. There is adequate attention to the employment of physical therapeutic procedures, medication is discussed briefly, the importance of rest is stressed, and different physical therapeutic procedures are carefully outlined and graded during the various stages of recovery. The value of x-ray therapy is mentioned and proper diet and supportive measures discussed. The use of transfusions to overcome anemia is mentioned, and the place of cortisone and corticotropin (ACTH) in management of rheumatoid arthritis of the spine is also described briefly. Next the discussion turns to the diagnosis of rheumatoid arthritis of the spine that is of gradual onset. The signs of onset of this gradual type are described, and the differential diagnosis is discussed. Again the employment of physical therapeutic measures is well discussed, x-ray therapy is mentioned, the value of home programs of physical therapy is stressed, and the need for orthopedic consultation is brought out.

This is a good general discussion of the whole subject of rheumatoid arthritis of the spine. The photography is good, the narration is satisfactory, and the only criticism of the filming is that some of the scenes are superfluous. By more judicious cutting, the film might be shortened by 5 or 10 minutes. Presumably, this picture was made for medical officers in the service who are treating these patients under conditions where time and expense is no consideration to the patient. It would be of interest to general practitioners, physical therapists, and nurses.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Prenatal Injuries: Right to Recover Damages For.—The plaintiff, as administrator of the estate of Coleen Ann Drabbels, deceased, sued for damages for Coleen's death, allegedly due to the defendant's negligence. From a judgment for the defendant, the plaintiff appealed to the Supreme Court of Nebraska.

The plaintiff's petition alleged that the defendant, the Skelly Oil Company, is engaged in the selling of bottled gas under the trade name of Skelgas and that the defendant, Frey, is the agent of the Skelly Oil Company at Gordon, Neb., for the handling, sale, and delivery of Skelgas to the public. It is alleged that Virgil W. Drabbels purchased a container of Skelgas from the defendant, Frey, which, because of the defective condition of the container, exploded and caused the death of the decedent. The explosion occurred on July 2, 1948. The decedent, the unborn child of Audrey Drabbels, wife of Virgil W. Drabbels, was born dead on July 5, 1948. The petition also alleges that at the time of the explosion the pregnancy of Audrey Drabbels had advanced to a period of approximately eight months and that the unborn child was viable and capable of separate and independent existence. The defendant demurred to the plaintiff's petition on the ground that the decedent was dead when born, that the child was never an existing person, that there was never a person or estate for which the plaintiff could be appointed the administrator, and that the plaintiff had no legal capacity to sue.

The wrongful death statute of Nebraska, said the Supreme Court, is plain in stating that the right of action created by it exists only in cases wherein the injured person could himself have maintained an action for damages had he lived. It is clear, therefore, that the plaintiff can maintain no action for damages on account of the death of the child unless the child, had it lived, could have maintained an action against the defendants for the injury inflicted on it before its birth. The cases hold, the court continued, from a numerical standpoint at least, that damages for prenatal injury may not be recovered either by the injured child if it be born and lives or by its personal representative in the event of its death before birth from such injury. As was said in an Illinois case, "That a child before birth is, in fact, a part of the mother, and is only severed from her at birth, cannot, we think, be successfully disputed. The doctrine of the civil law and the ecclesiastical and admiralty courts, therefore, that an unborn child may be regarded as in esse for some purposes, when for its benefit, is a mere legal fiction, which, so far as we have been able to discover, has not been indulged in by the courts of common law to the extent of allowing an action by an infant for injuries occasioned before its birth. If the action can be maintained, it necessarily follows that an infant may maintain an action against its own mother for injuries occasioned by the negligence of the mother while pregnant with it. We are of opinion that the action will not lie." Following reference to that case and other cases, the Supreme Court of Nebraska held that a child born dead cannot maintain an action at common law for injuries received by it while in its mother's womb, and, consequently, the personal representative cannot maintain it under a wrongful death statute limiting such actions to those that would, if death had not ensued, have entitled the party injured to maintain an action and recover damages in respect thereof. An unborn child is a part of the mother until birth and, as such, has no juridical existence. Since no cause of action accrued to the child born dead, for injuries received before birth, the court concluded, none survived to the personal representative under the wrongful death statute. It would appear therefore, that an action of this character may not be maintained unless and until the right to bring it is afforded by legislative enactment. Accordingly, the judgment of the trial court in favor of the defendant was affirmed. *Drabbels v. Skelly Oil Co., 50 N. W. (2d) 229 (Nebraska 1951).*

Potassium Depletion in Surgical Patients. R. Patton, E. H. Ellison, E. T. Boles and R. M. Zollinger.—p. 726.

Acute Appendicitis in Infants.—Most infants with appendicitis are hospitalized after peritonitis has developed. This is due to (1) too liberal use of cathartics, (2) inability of the infant to localize his complaints, (3) inability of an underdeveloped omentum to assume a protective role, and (4) high position of the cecum, which tends to obscure the disease. Benson and associates review observations on 39 infants who were treated for acute appendicitis and its complications during the years 1936 to 1951 at two Detroit hospitals. The patients were 24 months of age or younger, but only three infants were under 12 months of age. More than two-thirds were boys. The symptoms had been present prior to hospitalization for from 6 hours to 14 days. The average rectal temperature in the infants with acute nonperforated appendicitis was 100.9 F; in infants with acute perforated appendicitis it was 102.8 F. An elevated leukocyte count is significant, but a low leukocyte count does not rule out appendicitis or its complications when the clinical picture is evident. Seven of the infants had acute appendicitis, 13 had appendicitis with perforation and peritonitis, and 19 were admitted with a perforated appendix and a mass in the right lower quadrant or pelvis. All six deaths occurred during the first 5 years of the 15 year period. Thus the mortality was reduced from 60% during the five year period 1936-1941 to zero during the 10 years 1941-1951. This is attributed to the fact that parents and physicians are more aware that appendicitis may occur in infants, and realize that surgical intervention is important. The availability and use of penicillin, streptomycin, and chloramphenicol (chloromycetin®) also have played an important role. The triad of abdominal pain, vomiting, and fever in infants must be considered to be due to appendicitis until proved otherwise.

The Nodular Thyroid.—The thyroids of 155 patients were examined because of the presence of a "single nodule." Studies were made also on 27 patients with cancer of the thyroid. Except for bizarre carcinomas and sarcomas, the histological picture was not related to survival. Gross blood vessel invasion as described by Graham is important in diagnosis of thyroid cancer, but not the microscopic picture often interpreted as such. The thyroid is abundantly supplied with blood vessels and tightly encapsulated. If there is hypertrophy, pressure within the capsule results in invagination of cells into the smaller vessels, a condition often wrongly interpreted as blood vessel invasion. The glands of 101 of the 155 patients who were operated on because clinically a single nodule was evident contained multiple nodules on examination. The incidence of cancer was not related to the incidence of the so-called "single nodule." Most of the patients with carcinoma were between 20 and 40 years of age; all three who were under 12 years of age had carcinoma. Seven of 14 male patients and 10 of 141 female patients had carcinoma. The presence of nodules necessitates surgical exploration in women over 18 whose glands show a rapid change in size in the absence of pregnancy or of hyperthyroidism, and in children and men immediately on discovery. Lobectomy is required for adequate study of a tumor and often is easier than simple excision of a nodule. In the 27 patients with cancer of the thyroid, 8 had been previously operated on for a nontoxic nodular goiter. This suggests that subtotal thyroidectomy does not protect against cancer. The authors show that diseased tissue can be completely excised with minimal deformity. They recommend total thyroidectomy rather than resection of only the affected lobe and isthmus, because there may be a tumor or a satellite in the opposite lobe. Radioactive iodine is of little value in the preoperative diagnosis, since a tumor may lie beneath normal thyroid tissue and thus show the same activity after a tracer dose of radioactive iodine as the normal thyroid. Radioactive iodine therapy in thyroid carcinoma is difficult to evaluate, because patients with untreated carcinoma of the thyroid can survive 20 to 35 years. In a few instances the use of ionizing radiation has produced excellent results.

Phlebectomy for Acute Thrombosis of Saphenous Veins.—Herrmann discusses a method of phlebectomy that has been employed for more than 15 years at the Cincinnati General Hospital as the definitive treatment for acute thrombosis of saphenous varices and veins. The author and his associates believe that the danger of this type of superficial venous thrombosis is in the spread of the thrombosis to the deep veins. Anticoagulants do not alter the thrombosis that has already taken place; if they are to be effective in limiting the spread of the thrombosis, they must be administered many weeks. The expense, as well as the difficulty of keeping the coagulability of the blood at the required level constitute problems. Complete excision of the vein and blood clots (phlebectomy) is a simple, safe, logical surgical procedure. When there is perivenous edema, the veins can be "shelled out" with minimum effort and least trauma to the surrounding tissues. If the operation is delayed until organization of the blood clots and cellular reaction about the veins becomes widespread, then complete extirpation of the veins and the blood clots becomes more difficult. The author believes that phlebectomy should be employed more

Generalized Decreased Bone Density. D. M. Gould.—p. 569.

Radioactive Iodine Uptake in Treated Hyperthyroidism.—Doses of 1 or 2 μc of carrier-free I^{131} were administered intravenously or orally to 88 healthy persons. Uptake determinations were performed 30 minutes, 1 hour, 3 hours, 6 hours, 24 hours, and 48 hours after administration of the tracer dose. Results showed that the iodine could be administered orally as well as intravenously. Repeated I^{131} uptake readings were then made at the same intervals in 60 patients with hyperthyroidism or a previous history of hyperthyroidism. Previous observations by other investigators on the initial rapid rate of accumulation of I^{131} by the thyroid were confirmed. In all patients more than two-thirds of the total of I^{131} accumulated in 24 hours was present in the gland within 6 hours. The total amount of I^{131} accumulated in the glands of treated hyperthyroid patients in remission was less than in untreated patients, but the treated patients retained their rapid rate of uptake. The thyroids of several patients suspected of having hyperthyroidism accumulated a normal maximum amount of I^{131}, but with a rapid rate of uptake. These patients are being followed. The importance of obtaining repeated uptake readings within 24 hours after administration of the tracer dose of I^{131}, particularly at 3 and 6 hours, is stressed.

Nitrogen and Potassium Metabolism in Poliomyelitis.—Results of biochemical studies in 17 patients acutely ill with poliomyelitis with respiratory involvement indicated that in general the disease has an acute catabolic, a subacute catabolic, and an anabolic phase. Deviations from this general pattern were observed in a number of cases. The pronounced negative nitrogen balance that occurs in the acute phase of poliomyelitis may be utilized as a prognostic aid in predicting the ultimate degree of neuromuscular involvement. The necessary biochemical determinations are measurement of the nitrogen excretion in 24 hours or, less preferably, of the urinary nitrogen concentrations when urine volume is adequate. This negative balance is accompanied by a precipitous drop in serum albumin, elevation of the globulin fractions, and a negative potassium balance. The rapid drop in serum albumin is an indication for administration of serum albumin or irradiated plasma for prevention of peripheral vascular collapse. Hypopotassemia, which was frequently present and may be detected by serum determinations, may be prevented by administration of 3 gm. or more of potassium daily. Hyperpotassemia with shock and respiratory acidosis may be observed, in which case therapy should be directed toward restoration of the pulmonary ventilation, diffusion, and improvement of peripheral vascular tone while potassium is not given orally and parenterally. Excessive sodium intake should be avoided, particularly during the acute catabolic phase, when it may predispose to hypopotassemia and metabolic alkalosis. Average requirements at this time are approximately 3 gm. and decrease to 1 gm. during the subsequent anabolic phase. During the course of the disease, occurrence of complications such as extension of the disease process, pulmonary edema or atelectasis, respiratory acidosis, metabolic alkalosis, and hemolytic reactions with hepatic involvement may be detected early by recurrence of increased nitrogen and potassium excretion.

Absorption of Amino Acid Mixture in Hypoproteinemia.—The jejunal absorption of an amino acid mixture (casein hydrolysate) was studied in six normal and five hypoproteinemic subjects, the aim being to determine whether or not there was any impairment in the jejunal absorption of an amino acid mixture in patients with hypoproteinemia as compared to that in subjects with normal serum protein levels. It was thought possible that impaired amino acid absorption might be a factor in the hypoproteinemia manifested by some patients who do not have obvious evidence of gross hepatic, renal, or intestinal disease. The normal subjects absorbed an average of 36.8% and the hypoproteinemic subjects an average of 27.9% of the nitrogen introduced. This difference in absorption is statistically significant. The reason for the decreased absorption of nitrogen from the casein hydrolysate solution by the hypoproteinemic subjects is not clear. Some degree of generalized edema was present in all except one of them, and in this patient the absorption of nitrogen was comparable to that of the controls. It is possible that in the edematous subjects edema of the intestinal mucosa was a factor in the decreased rate of absorption. Support for such an explanation is supplied by Elman, who found that patients with hypoproteinemia and resulting edema were unable to utilize orally administered protein hydrolysates (amigen®) normally.

Organic Sequelae of Electric Convulsive Therapy.—Gallinek is not concerned with the immediate postshock confusion, Korsakoff syndromes, memory defects, or the general reactions of blurring or blunting, characteristic of organic reactions, which are known to every shock therapist. The reactions described here are usually of a fleeting character and occurred in only a few patients. Three of the seven patients reported on had manic and paranoid syndromes. The manic syndrome in one became manifest two days after termination of the treatment, and the author gained the impression that neither memory impairment nor confusion is a factor in this psychosis. On the other hand, paranoid syndromes were observed only in association with considerable confusion. No relationship between the original psychosis for which the patients were treated and the induced psychosis could be found. These syndromes almost never lasted more than 10 days. Dysgnostic phenomena were observed in patients who were treated for depression, including one in whom depressive and schizophrenic features were coexistent. Nothing in the past histories of these patients seemed to predispose them to dysgnostic or pseudoillusional difficulties. The syndromes were observed in association with mild confusion and memory difficulties. The chief distortion of gnostic function was that faces of strangers gave the impression of being familiar, inducing one patient to address strangers. The second disturbance is the opposite of the first one. Familiar faces, like the face of husband, mother, or baby, may impress the patient as strange, the strangeness being indefinable, never interfering with recognition. The third disturbance is that faces of people are perceived as grotesque and caricature-like. Occasionally this impression provoked hilarious laughter. The phenomena usually do not arise before most of the original symptoms have disappeared, and they persist for a short time after complete disappearance of the underlying psychosis. They do not have the characteristics of a hallucination or an illusion, since their pathological nature is clearly recognized by the patients.

Aluminum Gels for Control of Renal Calculi.—Shorr's regimen for control of phosphatic renal calculi was used in 37 patients who had a tendency to formation of this type of calculi, and in whom the tissue damage, obstruction, and infection present in the urinary tract should have enhanced the rate of stone growth. Twelve patients had had unilateral nephrectomy (11 for calculi and one for tumor), so that 62 kidneys were studied. When the regimen was begun, 35 kidneys in 26 of these patients contained calculi, and in 11 patients the kidneys were stone-free. Seventeen kidneys were hydronephrotic. All but eight patients had pyuria. The aluminum hydroxide gels administered for prophylaxis were amphojel,® usually in doses of 40 cc., or basaljel,® in doses of 30 cc., after meals and at bedtime. For individual patients the dosages were varied slightly. The patients followed a diet supplying approximately 1,300 mg. of phosphorus and 700 mg. of calcium per day. Each was urged to maintain a daily fluid intake of approximately 3,000 cc. Antimicrobial drugs and urologic measures were employed according to the usual indications. Comparison of the clinical courses of these patients before institution of the regimen with their courses during the prophylactic program showed that the aluminum gel and dietary therapy reduced stone formation. For instance, 78 operations for removal of calculi had been carried out before the prophylactic regimen was begun, but during the program only four operations were required, for removal of stones that had been present before the start of the regimen or had developed following lapse in therapy. Five patients provided individual control studies by voluntarily discontinuing therapy, and in three of these calculi promptly recurred. This study includes several of the cases reported by Shorr and Carter, and substantiates their clinical findings. The experimental work of Vermeulen and his associates and the clinical observations of Satterthwaite corroborate this study.

Globus Hystericus.—Rigby believes that so-called "globus hystericus" is an important disease and that too little time has been spent in its diagnosis and treatment. He discusses the difficulty in differentiating functional disturbances and organic disease at the level of the upper esophagus and reports his experiences with 98 patients referred to him because of a "lump in the throat." These patients should be put at ease, and, in taking the history, attention should be given to emotional disturbances. For most of the patients a diagnosis of a mild type of hysteria had been made. The others were found to have organic disease, which was treated. X-ray examinations of the neck revealed two characteristic phenomena: (1) marked hypertrophy of the lingual tonsil, which is seen by indirect examination of the pharynx, and is confirmed by lateral x-ray films of the neck, and (2) marked lipping or osteoarthropathy of the anterior borders of the cervical vertebrae. Marked lipping of the cervical·vertebrae with the so-called inflammatory reaction in the soft tissues anterior to the lipping may set off the trigger mechanism that produces the globus hystericus. To the author this seems as logical as such explanations as hyperirritability of the mucous membrane, spasm of the cricopharyngeus muscle, or irritability caused by enlarged lymph nodes. He found psychotherapy effective in treating these patients. He concludes that "globus hystericus" or a "lump in the throat" can be a symptom of functional disorder or of organic disease. The diagnosis and treatment is based on a complete history and physical examination.

Vitamin B_{12} to Relieve Pain in Trigeminal Neuralgia.—Relief of neuropathy in pernicious anemia by administration of vitamin B_{12} suggested its employment in other nervous disorders. It relieved the pain of alcoholic, diabetic, and other peripheral neuritides, but in early tests it failed to alleviate the pain of trigeminal neuralgia. Nevertheless when solutions of greater potency became available, therapy was undertaken in 13 cases of trigeminal neuralgia begining in May, 1950. The first six patients were given 1,000 µg doses biweekly or triweekly for four to eight weeks, and the pain was markedly relieved within the first week, usually after the second injection. In four patients the sharp lancinating type of pain was replaced by nonradiating burning paresthesia in the same area. This paresthesia disappeared with continuance of therapy, although it was more resistant to treatment. In two cases, when therapy was interrupted for about one week while the burning sensation was still present, the lancinating pain returned but was relieved after the first of six daily injections of 1,000 µg each. Because symptoms returned when therapy was interrupted and burning sensations persisted, daily injections for 10 days were given to the last seven patients. At the time of this report there have been no recurrences in this series. None of these patients has requested other therapy. Five of the patients had received other therapy in the past, such as nerve section or alcohol block. Relapses after these treatments made these patients reluctant to undergo further surgical intervention. Four of these proved to be the most resistant patients in the series, but the ultimate degree of relief was the same as in others. After a year of experience with massive doses of vitamin B_{12} it is felt that this substance offers promise of prompt relief of the most distressing aspects of the pain, with ultimate complete or virtually complete relief of the secondary burning paresthesia.

Chronic Ulcerative Colitis and Pregnancy.—Patterson and Eytinge reviewed the cases of 16 women in whom ulcerative colitis and pregnancy concurred. The diagnosis of chronic ulcerative colitis was made by proctoscopy and barium enema examination of the colon. Eight of the 16 patients became pregnant while the colitis was moderately active. These eight patients had 18 pregnancies, with 16 viable children (1 pair of twins), 1 fetal death that seemed unrelated to the ulcerative colitis, 1 therapeutic abortion, and 1 spontaneous abortion. Four patients thought that pregnancy improved the colitis, three thought that the colitis was aggravated during and after pregnancy, and one said that pregnancy had no effect. Three patients who became pregnant at a time when their colitis was inactive had four pregnancies with three viable children, and one therapeutic abortion. Two of these three patients thought that pregnancy had no effect on their condition and one believed that it aggravated her symptoms. Five patients in whom ulcerative colitis developed during pregnancy were acutely ill. In three cases viable infants were delivered. In one patient the process became quiescent, and she has since had two children and is now pregnant for a third time. One patient died shortly after a miscarriage. One patient had two pregnancies but no viable children. In the other two patients the disease continued to be active; one required ileostomy two months after delivery. Pregnancy that occurs during an inactive stage of ulcerative colitis is usually well tolerated. Pregnancy in a patient with mild or moderately active symptoms may produce improvement or aggravation. If possible, pregnancy should be delayed until the colitis is quiescent, but regardless of symptoms the pregnancy can usually be continued to term with birth of viable children. Ulcerative colitis that develops during pregnancy is virulent and may be fatal.

Decamethonium Bromide in Convulsive Shock Therapy.—Drugs that produce muscular relaxation, prevent fractures, minimize muscular soreness, and reduce the strain on the heart and lungs are of obvious advantage to the patient undergoing therapeutic convulsions. This report is concerned with the clinical evaluation of decamethonium bromide as a muscle relaxant and is based on the study of 117 consecutive patients who required a total of 1,302 electric shock treatments, of which 869 were modified by decamethonium bromide, 326 by *d*-tubocurarine, and 107 by dimethyl ether of *d*-tubocurarine chloride. Brody concludes that curare and decamethonium are dissimilar drugs, although both produce muscular relaxation. The weakness produced by curare simulates myasthenia gravis, while the action of decamethonium simulates the paralysis of botulism. Because of their dissimilarity, there will be situations in which one is preferred to the other. In shock therapy, the advantages of decamethonium bromide seem to outweigh the disadvantages. The chief advantages are the shorter action of the drug and the relative sparing of the tongue and larynx; the disadvantages are the lack of antidote and the inability to predict the first dose. These disadvantages can be handled by the method of fractional administration of decamethonium bromide. All drugs mentioned are satisfactory relaxing agents, but Brody prefers decamethonium in shock therapy.

Bedside Method for Sodium Analysis.—Most methods for measurement of sodium in urine or other excretory fluids have been indirect and not entirely satisfactory. The method described requires only one reagent, a uranyl zinc acetate solution. The simple procedure is a new application of an established method for chemical analysis of sodium, Kolthoff having recognized in 1927 that uranyl zinc acetate would react with sodium to produce an insoluble salt. The sodium is thus precipitated, and the amount of precipitate is read as 1+ to 5+, each degree representing a definite range of sodium ion concentration expressed in milliequivalents per liter. The preparation of the reagent solution and the equipment required are described. The test procedure consists of placing one drop of clear (if necessary, filtered) fluid to be tested into a test tube, adding eight drops of reagent, shaking gently, and reading in eight minutes. The value of this determination lies in its simplicity. It may be carried out in the wards, on home visits, or be used in the office. It permits detection of the low salt syndrome or sodium retention in cardiac failure. It is also helpful in checking adherence to a low salt diet.

Parenteral Use of Sodium Para-Aminosalicylic Acid.—Several European, particularly Swiss, investigators have administered *p*-aminosalicylic acid solution by continuous intravenous drip to patients with tuberculous meningitis and miliary tuberculosis. This method of treatment is now being tried in this country. The material used is lyophilized sterile sodium *p*-aminosalicylic acid, reconstituted with distilled water to make a 3% solution. Heparin, 5 mg. per 1,000 cc., is added to the intravenous solution. Ordinarily 15 gm. of *p*-aminosalicylic acid are given over a period of four hours, and this dosage is repeated after a rest of two or three hours. Most patients tolerate a daily dose of 30 gm. Blood levels of *p*-aminosalicylic acid are generally 20 to 30 mg. per 100 cc. within an hour or two of administration. Spinal fluid levels are 11 to 15 mg. per 100 cc. within two to three hours after the start of treatment. Parenteral *p*-aminosalicylic acid has been used in tuberculous meningitis, miliary tuberculosis, as an adjuvant before and during surgery, especially in patients whose bacilli are streptomycin-resistant, and in patients who do not respond to standard therapy. The authors discuss the histories of 3 of 14 patients to whom *p*-aminosalicylic acid was given by the parenteral method. Six of the 14 had tuberculous meningitis, 4 had miliary tuberculosis, 1 had a combination of the two, and 3 had not responded to standard treatment. Two of the patients with tuberculous meningitis died. Four are greatly improved, three having been discharged to their homes. The authors believe that the treatment was begun too late in the patients who did not respond.

Brain Tumors Complicating Pregnancy.—Reeves reviews six cases in which brain tumor complicated pregnancy and shows that each of these cases presented a different problem and required individual study and treatment. When intracranial pressure increases, operative intervention cannot be postponed. Furthermore, because of the increased intracranial pressure associated with spontaneous delivery, cesarean section is safer than spontaneous delivery in women with brain tumor. If an electroencephalographic tracing of a pregnant woman indicates the presence of an expanding intracranial lesion, additional diagnostic procedures and treatment should be considered. While any surgical intervention in a pregnant woman increases the chance of abortion, the first case here presented indicates that even convulsions are tolerated without resultant abortion. That the neurosurgeon is faced with complex and difficult problems if brain tumor occurs during pregnancy becomes evident from cases reported in the previous literature as well as from the six here described.

BOOK REVIEWS

Posture and Pain. By Henry O. Kendall, Director, Physical Therapy Department, Florence P. Kendall, Assistant Director, Physical Therapy Department, and Dorothy A. Boynton, Physical Therapist, Physical Therapy Department, Children's Hospital School, Baltimore. Cloth. $7. Pp. 204, with 159 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1952.

The relation of faulty posture to the production of pain, as presented in this book, is based on the authors' many years of experience as physical therapists in the physical therapy department at Children's Hospital School in Baltimore.

The book deserves special commendation for its attractive format and excellent illustrations. The first chapter considers standard posture, which, according to the text, refers to an "ideal" posture rather than an average posture. It is further indicated in the text that "the authors have not seen an individual who matches the standard in all respects." The second chapter, which is about postural faults, considers deviations from this "standard." It seems peculiar that deviations from a "standard" that has not been observed to exist should be considered as postural faults. It would seem more proper that postural faults be considered as deviations from an acceptable average posture.

The third, fourth, and fifth chapters contain a simple yet practical analysis of muscle action and imbalance as related to faulty posture. The importance of muscle strength and tightness or loss of extensibility as a contributing factor to poor posture is discussed. A systematic and practical procedure for posture analysis is discussed in the sixth chapter. In the section of the text on the treatment of faulty posture and pain associated with faulty body mechanics this statement is most properly included: "In discussing pain in relation to postural faults, there are those, however, who are dubious. They often ask the very pertinent question why it is that many cases of faulty posture exist without symptoms of pain. They also question why seemingly mild postural defects give rise to symptoms of mechanical and muscular strain." There follows a logical discussion of this controversial subject. The opinions expressed in the text are worthy of consideration, even though some physicians may not agree. The physician may find many of the suggestions regarding the use of various physical therapeutic agents useful in prescribing physical therapy and supports for the treatment or prevention of faulty posture and the treatment of painful conditions of the neck, back, and extremities.

Infant Development: The Embryology of Early Human Behavior. By Arnold Gesell, M.D. Cloth. $3.50. Pp. 108, with illustrations. Harper & Brothers, 49 E. 33rd St., New York 16, 1952.

This book is beneficial to pediatricians and others confronted with the evaluation of physical and mental development of infants and children. This volume presents an informal orientative introduction to growth and forms of behavior at advancing maturity levels from birth to the 10th year. It attempts to show that there is a significant continuity of functional and physical development in both the prenatal and postnatal phases of human growth. A study of premature infants throws light on growth changes that ordinarily take place in the prenatal period. There is a discussion of comparative anatomy in lower animals emphasizing the embryonal development of the eyes and eye and hand behavior. A pictorial chapter has 50 photographs from their feature length film "The Embryology of Human Behavior" to demonstrate the progression of the growth cycle. These excellent action photographs clearly illustrate developmental patterns at various age levels. A chapter on examination methods and diagnostic procedures helps one to evaluate both the normal and abnormal child. An appendix includes sketches and charts of growth patterns of the 28-week-old infant, a bibliography, and a list of silent and sound movies by the Yale Films of Child Development.

Brain Tumors of Childhood. By Henry M. Cuneo, M.D., Assistant Clinical Professor of Neurological Surgery, University of Southern California, School of Medicine, Los Angeles, and Carl W. Rand, M.D., Clinical Professor of Neurological Surgery, University of Southern California, School of Medicine. Publication number 104, American Lecture Series, monograph in Americal Lectures in Surgery, edited by Michael E. De Bakey, M.D., Professor of Surgery and Chairman of Department of Surgery, Baylor University College of Medicine, Houston, and R. Glen Spurling, M.D., Clinical Professor of Surgery, University of Louisville, Louisville, Ky. Neurosurgical Division, editor: Barnes Woodhall, M.D., Professor of Neurosurgery, Duke Hospital, Durham. Cloth. $5.75. Pp. 224, with 61 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1952.

This compact volume is in the American lecture series. In it, the authors summarize their experiences with brain tumors in children at the Children's Hospital in Los Angeles during the past decade. Eighty-three verified cases of brain tumor and/or granulomatous lesions resembling tumors are discussed.

Each of the first 12 chapters is devoted to one pathological type of tumor. In the final chapter, the authors discuss the general symptomatology and differential diagnosis of these lesions as they occur in childhood. A brief quotation from some authority in this field at the beginning of each chapter sets the stage for the discussion that follows. A few case reports are included; these are brief and to the point, with excellent illustrations. Selected references, mostly in English, are given at the end of each chapter.

The authors' experiences with cerebellar astrocytoma and medulloblastoma emphasize the importance of biopsy and histological verification of the tumor type before administration of x-ray therapy. The failure of ventricular estimation to differentiate between cerebellar and third ventricle tumors is properly emphasized and leads the authors to advise routine ventriculography for children who have symptoms of posterior fossa tumors.

One wonders at the inclusion of cases of spongioblastoma polare in the chapter on glioblastoma multiforme rather than in the chapter on astrocytoma, a tumor with which it is more closely related. This minor pathological point is compensated for by the inclusion of discussion of the granulomatous lesions, not ordinarily considered under the heading of brain tumors in childhood.

The similarity of their results with those reported in the monograph by Bailey, Buchanan, and Bucy in 1939, emphasizes the enormity of the therapeutic problems. This review will be especially valuable to pediatricians and to neurologists and neurosurgeons who do not see many patients in this age group; however, it can be read with profit by all physicians who are interested in neoplastic diseases of the brain.

A Review of Nursing with Outlines of Subjects: Questions and Answers. By Helen F. Hansen, R.N., M.A., Inspector, Schools of Nursing, State Department of Public Health, California, Sacramento. Seventh edition. Cloth. $5.75. Pp. 844. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1952.

The author of this review of nursing has extensive experience in educational administration. Her positions as chief at the bureau of registration of nurses in California and executive secretary of the board of nurse examiners in California were excellent background for the preparation of this book.

The material is presented in outline form, and each section is followed by a battery of tests on the preceding subject. Correct answers to these tests are found at the back of the book. In this edition, the author has attempted to include more comprehensive situation type questions to stimulate additional reading. True-false and completion type questions have been reduced in number.

The fields covered are chemistry, anatomy, and physiology, psychology, nutrition, public health, pharmacology, and thera-

---

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

peutics, and microbiology. In patient care, the areas included are medical care, communicable disease, and surgical, obstetric, pediatric, and psychiatric nursing. Also reviewed are nursing history, professional relationships, and sociology.

In this new edition, the chapter on pharmacology and therapeutics has been revised. Public health aspects have been enlarged to include international health problems and the World Health Conference. Also added is material on the role of poisons in industrial health, the hygiene and nursing care of patients receiving x-ray therapy, and the anatomy and physiology of the male reproductive system. There are no illustrations, plates, or bibliographies.

This book should serve a useful purpose for those who wish an outline to guide their review of the field of nursing.

Textbook and Guide to The Standard Nomenclature of Diseases and Operations. By Edward T. Thompson, M.D., F.A.C.H.A., Senior Surgeon, Public Health Service, and Adaline C. Hayden, R.R.L. Cloth. $8. Pp. 619. Physicians' Record Company, 161 W. Harrison St., Chicago 5, 1952.

This is a new book designed, as its title implies, to serve as a guide to the use of the recently published fourth edition of the "Standard Nomenclature of Diseases and Operations." In it, the authors have succeeded in answering practically all questions that may arise in the use of the nomenclature, either for physicians or medical record librarians. It will serve an invaluable function as a textbook in the training of medical record librarians and as a reference book in any institution using the "Standard Nomenclature." Probably few physicians will read this book from cover to cover, but medical record librarians can use it with great effectiveness in discussing certain problems of classification with the professional staff members of their institutions by pointing out appropriate paragraphs.

There are few criticisms; however, it is perhaps unnecessary to discuss eponyms in two places (pages 189 and 213). The book contains a list of disease entities that are not classified but does not state what to do with them when such diagnoses arise. The authors are to be complimented on the preparation of this difficult and useful book, which is presented with good type and in attractive form.

Manual for Medical Records Librarians. By Edna K. Huffman, R.R.L., Medical Records Consultant. Third edition. Cloth. $7.50. Pp. 484, with 125 illustrations. Physicians' Record Co., Publishers, 161 W. Harrison St., Chicago 5, 1952.

This book was planned as a day to day guide for problems arising in medical record libraries. Most of the previous edition has been completely rewritten to bring material up-to-date. The chapter on organization and management now contains job descriptions for the various tasks assumed by medical record library personnel. One chapter has been devoted to the medical audit. This subject is timely and has attracted much attention in the last decade. Some of the old illustrations have been completely omitted and/or replaced by new ones.

The material is discussed in a clear, concise style, and, after a careful review of the volume, there can be no doubt in the mind of the medical record librarian as to what procedure she should follow in maintaining an efficient medical record department. The book is printed in clear type on good paper and is attractively bound. It is wholeheartedly recommended to all hospital personnel who deal, even to the slightest degree, with medical records.

Health Instruction Yearbook 1951. Compiled by Oliver E. Byrd, Ed.D., M.D., F.A.P.H.A., Professor of Health Education, and Director, Department of Hygiene, School of Education, Stanford University, San Francisco. Foreword by Bernice Moss, M.A., Ed.D., President, American Association for Health, Physical Education, and Recreation, Salt Lake City. Cloth. $3.50. Pp. 236. Stanford University Press, Stanford University, California; Oxford University Press, Amen House, Warwick Sq., London, E.C.4, 1951.

This is another book in the series that was begun eight years ago, making this the ninth "Yearbook." Previous editions have been reviewed in THE JOURNAL, and there is no new comment to be added with regard to this edition. It is a useful reference book for the desk of anyone engaged in public health or health education.

Experiments in Biochemistry. By Max S. Dunn, Ph.D., Professor of Chemistry, University of California, Los Angeles, and William Drell, Ph.D., Research Fellow, California Institute of Technology, Pasadena. Cloth. $5. Pp. 197, with 12 illustrations and 46 data sheets for experiments. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 18; Aldwych House, Aldwych, London, W.C.2, 1951.

This book, designed as both a reference work and laboratory guide, accomplishes to a large extent the purpose for which it was written. It contains 46 experiments, which have been chosen to cover as wide a field as possible and at the same time to serve as an introduction to the use of the various laboratory techniques that are employed in investigative biochemistry. The experiments include syntheses, analyses, isolations, and purification and/or identification of proteins, amino acids, fats, carbohydrates, purines, pyrimidines, vitamins, and enzymes. The analytical experiments are chosen to include animal, microbiological, and instrumental as well as chemical procedures.

Each chapter is prefaced with a brief discussion of the subject of the experiment. These discussions, although brief, are made broad by including numerous references to original literature, reviews, and books. These references are included as a bibliography at the end of the book. Many of the experiments contain elaborate explanatory notes. The volume also contains an appendix, which gives details with respect to apparatus employed, reagents used, and special techniques required in various experiments. First aid hints, instructions to students, and suggestions to instructors are also contained in this section. Data sheets, included at the end of the book, can be conveniently filled out by the student and cut from the book. An adequate index is also included.

Case Record from a Sonnetorium: Poems. By Merrill Moore. Cartoons by Edward St. John Gorey. Cloth. $1.50. No pagination. Twayne Publishers, 42 Broadway, New York 4, 1951.

Dr. Merrill Moore is said to have written more sonnets than any other poet. His sonnets are original in form to the extent of being referred to by the poet himself as illegitimate. They are not necessarily medical. In fact, one may find on opposing pages sonnets referring, respectively, to eels and to love. Along with these sonnets goes a running series of cartoons. The cartoon has no necessary relationship to the sonnet with which it shares the page, but the cartoons themselves are supposed to constitute a series, which is, to say the least, highly fanciful. Physicians who like poetry will find this an amusing volume if they choose to read it in that vein, or if they wish to think more deeply they can find material here for that.

Eleventh Semiannual Report of the Atomic Energy Commission. United States Atomic Energy Commission. Paper. Pp. 211, with illustrations. Govern. Print. Off., Washington 25, D. C., 1952.

The three main divisions of this book are (1) a summary of the major activities in atomic energy programs from July to December, 1951, (2) a condensed Atomic Energy Commission annual financial report for the fiscal year 1951, and (3) a review of the applications of atomic energy to plant science. The last 76 pages consist of appendixes giving concrete details to document the preceding material.

Every page of the book is of interest to the physician either as a citizen concerned about the multifarious activities of the government or as a scientifically trained person watching for possible applications of atomic energy in the healing arts. It is therefore hard to single out passages of particular importance, except perhaps the section (pages 34 to 42) on biology and medicine, which describes the almost inconceivably extensive plans for laboratory facilities for the biologic and medical research program. It is stated that the total value of such facilities completed or approved for construction will approximate 30 million dollars. The status of the Argonne Biological Laboratory, Argonne Cancer Hospital, Brookhaven Biological Laboratory, Hanford Aquatic Laboratory, and Los Alamos Biomedical Laboratory is briefly summarized. Among the projects dealing with protection from injury by radiation is one (page 36) on chelating agents, chemicals that can be taken internally to hasten the excretion of radioactive elements that have become fixed in the animal body. The book is recommended to everyone interested in the possible relations of radioactivity to disease in man.

QUERIES AND MINOR NOTES

POISONOUS GARDEN PLANTS

To the Editor:—*I would like reliable information about hazardous or toxic plants commonly found in gardens. What are the toxic constituents, and what antidotes should be used for poisoning by them? I have had inquiries concerning the danger for children of eating oleander berries.*

Robert N. Philips, M.D., Chico, Calif.

Answer.—Only a few garden plants are poisonous by contact, but many others are poisonous if eaten, especially those in the family Solanaceae and the rhododendrons, mountain laurel, Christmas rose, and monkshood. A complete list of poisonous garden plants will be found in Taylor's "Encyclopedia of Gardening" (ed. 2, New York, Houghton Mifflin Company, 1948) in the section on poisonous plants, in which the part of each plant that is poisonous is specified.

The seeds and juice of oleander (Nerium oleander) are dangerously poisonous, as are many other plants in the family Apocynaceae. The poison in oleander is the glycoside oleandrin. Many other garden plants contain dangerously poisonous alkaloids; the best references for these are Henry's "Plant Alkaloids" (ed. 3, Philadelphia, The Blakiston Company, 1939) and the "Dispensatory of the United States of America" (Osol, A., and Farrar, G. E., Jr., editors, ed. 24, Philadelphia, J. B. Lippincott Company, 1947). Patients should be urged to keep part of the suspected plant for identification, as this may be the only clue to the alkaloid or glycoside causing the poisoning. Treatment should be based on this identification. Reference should be made to Sollman's "Manual of Pharmacology and Its Applications to Therapeutics and Toxicology" (ed. 7, Philadelphia, W. B. Saunders Company, 1948) and, especially, to "The Pharmacological Basis of Therapeutics" (Goodman, L., and Gilman, A.: New York, The Macmillan Company, 1941).

HYPERTENSION IN HIGH SCHOOL BOYS

To the Editor:—*In routine physical examinations, a number of high school boys with a systolic blood pressure higher than 150 mm. Hg and a pulse rate faster than 110 per minute were found. At what level of blood pressure is it safe to accept a high school boy for full athletic activity? What are the proper pulse rate ranges for acceptance and rejection of these boys? I maintain that it is not wise to accept a boy with a relatively high blood pressure or pulse rate, even if no organic disease is demonstrated, for such a boy is potentially hypertensive.*

M.D., Massachusetts.

Answer.—It is unusual to encounter "a number of boys" with systolic blood pressure readings over 150 mm. Hg, although blood pressure in the adolescent and young adult age periods is known to be labile. One group of observers found this degree of hypertension in less than 1% of 16-year-old boys (Graham, A. W.; Hines, E. A., Jr., and Gage, R. P.: Blood Pressures in Children Between the Ages of 5 and 16 Years, *Am. J. Dis. Child.* 69:203 [April] 1945). Emotional tension was apparently considered and ruled out as a factor causing the hypertension and tachycardia in the cases described in the query. Possibly a technical error was made in the determinations; for example, the use of a narrow "pediatric" cuff (4 to 9 cm. in width) would produce a false high reading, as would failure to wait for the appearance of sounds synchronous with each heart beat before recording the reading for systolic pressure. A recent statement by the American Heart Association is relevant to this point. (Recommendations for Human Blood Pressure Determinations by Sphygomanometers, *J. A. M. A.* **147**:632 [Oct. 13] 1951.) The finding of a pulse rate of 100 or more per minute among high school boys is also rare, and it supports the validity of the blood pressure determinations. Diastolic pressures of the subjects were not mentioned. Elevation of diastolic pressure is of equal or greater importance than the systolic pressure.

The normal blood pressure is best described as a range. The normal range for systolic pressures of adolescents and high school age youths is probably 105 to 135 mm. Hg and the normal diastolic range is 60 to 85 mm. Hg (Master, A. M.; Dublin, L. I., and Marks, H. H.: The Normal Blood Pressure Range and Its Clinical Implications, *J. A. M. A.* **143**:1464 [Aug. 26] 1950). Youths with blood pressures persistently higher than these values should be thoroughly examined to rule out possible causes of elevated blood pressure, including nephritis, coarctation of the aorta, polycystic and hypoplastic kidneys, pheochromocytoma, and Cushing's syndrome. Those youths with no demonstrable cause for elevated systolic pressure of 135 to 145 mm. Hg or diastolic pressure of 85 to 90 mm. Hg and who do not have cardiac enlargement could be permitted to take part in competitive athletics, provided there is medical supervision. It is reasonable, however, that, even when results of examination are normal, those boys with systolic pressure over 145 mm. Hg or diastolic pressure over 90 mm. Hg should not be permitted to engage in competitive sports. Cardiac enlargement and intracranial hemorrhage, the complications to be feared, are more likely to occur with the increased hypertension brought about by the emotional and physical stress of participation in competitive sports. These students should, however, be permitted to participate freely in a supervised program of physical education, in which there are opportunities for rest and the stress of competition is lacking. The mean pulse rate at this age is about 75 beats per minute. The upper limit of resting pulse rate for acceptance for competitive sports probably is 95 beats per minute.

Reported experience in the Army supports the opinion that transient hypertension of 150 mm. Hg or more and transient tachycardia of over 100 beats per minute appreciably increase the chances of hypertension developing in later years (Levy, R. L.; White, P. D.; Stroud, W. D., and Hillman, C. C.: Sustained Hypertension: Predisposing Factors and Causes of Disability and Death, *J. A. M. A.* **135**:77 [Sept. 13] 1947). When those two conditions occur together the likelihood of sustained hypertension later in life is even greater.

RHEUMATOID ARTHRITIS

To the Editor:—*Are gold salts and cortisone or corticotropin (ACTH) considered to have synergistic action? Is their simultaneous use advisable in treatment of rheumatoid arthritis?*

Robert J. Ralston, M.D., Holyoke, Colo.

Answer.—To date, opinions among rheumatologists regarding the combined use of cortisone or corticotropin (ACTH) and gold salts have been variable and tentative. Such a program of treatment has been termed "hopeful," "encouraging," "of no advantage," "disappointing," and even "possibly harmful." Use of the combination has been based on the premise that the relatively prompter, though generally temporary, antirheumatic effects of cortisone or corticotropin might be sustained by the slower acting gold salts; however, by definition, such an effect is supplementary rather than synergistic. In any event, the desired result is remission of the active, inflammatory reactions of the rheumatoid arthritis.

In the investigations of the possibility of remission from combined use of cortisone or corticotropin and gold salts, treatment with the gold salts has been started sometimes several weeks before, sometimes several weeks after, and sometimes concomitantly with, administration of the hormone and has then been continued beyond the period of hormonal treatment. A few instances have been cited that suggest that the hormonally induced remission has been prolonged by gold salts, but, in gen-

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

eral, no additive effect has been obtained in most patients receiving treatment with the combination. About 85 rheumatoid patients have received this combined treatment from at least seven investigators, according to the literature. Most of the data concerning these patients have been cited in discussions or other brief references. According to these reports, about 20% (18 patients) have had some prolongation of the hormonally induced antirheumatic effects, which may be attributable to the associated administration of gold salts; however, interpretation of the results in these patients is complicated by multiple and variable factors of both the disease and details of treatment. More experience with the combined use of these substances is required before such use could be considered advisable in the treatment of rheumatoid arthritis. In the meantime, if such a program is undertaken, it should be considered to be on an investigative basis.

TUBERCULOSIS, NEUROSIS, AND PREGNANCY

To the Editor:—*A 32-year-old housewife wants to have a baby. She has had minimal bilateral tuberculosis that has been arrested for over a year and a psychoneurosis for four years, which is greatly improved but still produces occasional annoying anxiety attacks. She is happily married and has one child, 5 years old. Her first attack of tuberculosis, at the age of 19, produced a small lesion confined to the right apex. This was arrested in six months, and she continued to be in good health until the birth of her child. Because of poor living conditions and malnutrition, which are not present now, tuberculosis spread to the left apex. The disease was arrested with bed rest. The patient is anxious about her health but is an intelligent woman and is capable of handling her household duties. The child is in good health, and the husband is intelligent and cooperative. Should the woman be allowed to become pregnant now, should she wait until a later date, or is a pregnancy inadvisable at any time?* *M.D., Pennsylvania.*

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—The pulmonary lesions of the patient under consideration should be inactive for at least two years before she becomes pregnant. Inactivity is defined by the National Tuberculosis Association as follows: "Lesions as observed in serial roentgenograms must be stable except for extremely slow shrinkage, and there must be no roentgenologic evidence of cavity. Symptoms of tuberculous origin must be absent. Sputum, if any, must be found negative for tubercle bacilli repeatedly, not only by concentration and microscopic examination but also by culture or animal inoculation. When the patient is not raising sputum or when there is any question concerning the authenticity or adequacy of expectorated sputum specimens, the fasting gastric contents or pulmonary secretions which have been aspirated from the tracheobronchial tree should be examined by culture or animal inoculation." Advice in the case in question must necessarily be influenced by the economic and social situation as well as by the degree of psychoneurosis involved.

Answer.—The problem is twofold, consisting of tuberculosis and mental instability. The tuberculosis should be thoroughly resolved before any thought is given to another pregnancy. Although detailed history and roentgenograms are not available, it seems that this is one of those smoldering types of disease that drags on for years and flares up on provocation. All foci should be adjudged arrested before pregnancy is permitted even if it requires a resection to extirpate the focus and assure an arrest at an earlier date than by ordinary rest treatment. This assurance is almost mandatory in view of the mental history. A complete arrest and cure of tuberculosis is now a relatively simple matter with present facilities for treating the disease. The problem of child-bearing will therefore depend on the severity and nature of the mental aberration. It may be only a temporary process due to transient worries and circumstances. There is mention of malnutrition that conceivably may be a contributing factor. If, after a proper diet and good mental environment for a year or two, there is no evidence of tuberculous activity she should be permitted to have another baby. If the mental disease is more serious or permanent or hereditary, it would be better not to think of pregnancy, even if the tuberculosis is entirely arrested.

IMMUNITY AGAINST COLDS

To the Editor:—*What procedures are there to build up a child's immunity against colds, bronchitis, and recurrent and relapsing respiratory infections?*

Charles L. Concklin, M.D., Corpus Christi, Texas.

Answer.—In an otherwise healthy child, aside from the ordinary rules of hygiene including adequate rest, food, and exercise in the open, there are no medical procedures to build up immunity. Isolation from persons with colds is important. Bronchiectasis may underlie repeated infections of the lower respiratory tract. Obstruction or other structural defects in the upper respiratory tract should be corrected. Enlarged tonsils rarely are a cause, and tonsillectomy has no effect on minor respiratory tract infections except repeated tonsillitis. Possible allergic factors must be eliminated. "Tonics," vitamins, antibiotics, and vaccines are of no value.

ARGYROSIS

To the Editor:—*Last December I instilled a few drops of mild silver protein (argyrol®) solution into a patient's lacrimal duct with a lacrimal syringe. I have done this on numerous occasions on other patients and have never had any trouble. This time as the argyrol was being injected, there seemed to be some extravasation into the soft tissue under the lower eyelid. I immediately stopped the injection. The discoloration under the eye caused by the mild silver protein has not disappeared and causes the appearance of a black eye. Can anything be done to cause the discoloration to disappear?*

M.D., Pennsylvania.

Answer.—Long continued use of organic silver salts in the form of mild and strong silver protein (argyrol® and protargol®) on mucous membrane and skin results in a permanent discoldration, which increases in depth as more silver is added. When introduced subcutaneously, the silver is deposited as an albuminate in collagenous tissues, in which it is reduced and a dirty gray-brown color is produced. The deposit excites no tissue reaction but remains permanently. The depth of discoloration depends on the amount of fluid injected and the proximity to the surface of the skin. Attempts to oxidize the silver and cause its absorption have been only partially successful. M. F. Weymann (*J. A. M. A.* **93**:1367 [Nov. 2] 1929) described a method by which he successfully treated conjunctival argyrosis. Argyrosis of the skin was successfully treated by Stillians and Lawless (*Arch. Dermat. & Syph.* **17**:153 [Feb.] 1928; *J. A. M. A.* **92**:20 [Jan. 5] 1929). The technique is to make up a 12% solution of sodium thiosulfate and a 2% solution of potassium ferricyanide. One part of the sodium thiosulfate solution is mixed with two parts of the potassium ferricyanide solution, and the mixture is injected intradermally, a platinum needle being used to prevent corrosion of the metal.

IRRADIATION IN BREAST CANCER

To the Editor:—*Has postoperative x-ray irradiation for cancer of breast any real therapeutic value?*

M.D., Rhode Island.

Answer.—The question cannot be answered with certainty, since the statistical evidence available is open to so much question. There have been claims of improvement of from 5% to as high as 15% in the five year survival figures in the treatment of cancer of the breast through the addition of postoperative x-ray therapy. The majority of surgeons do use postoperative x-ray therapy when the pathologist has returned the report of metastatic carcinoma of the axillary nodes, since it can be demonstrated that x-radiation is definitely cancerocidal for some cells. It seems the logical plan to follow since the question has not been more accurately settled.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, MAY-AUGUST 1952

Titles have been listed or abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past four months. Any of the journals, except those starred, will be lent by THE JOURNAL to individual subscribers in Continental United States and Canada and to members of the American Medical Association and its student organization. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each periodical. Three journals may be borrowed at a time for a period not exceeding five days. Requests should be addressed to the Library of the American Medical Association. Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "ab," abstracts; the asterisk (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For the author index see page 1745.

ACETANILID
  sulfhemoglobinemia after habitual use of Bromo-Seltzer, [Reynolds & Ware] *1538
ACETYLCHOLINE
  effect on pulmonary circulation and hypertension, Italy, 1485
ACID
  acetylsalicylic, effect on uricosuric action of probenecid, [Pascale & others] *1191
  Amino Acids: See Amino Acids
ACID—Continued
  p-aminobenzoic and sodium gentisate, treatment of pain in arthritis, 1263
  p-aminobenzoic, routine blood cultures, [Kotin] *1273
  p-aminosalicylic and streptomycin with isoniazid in tuberculosis, 1224—E; [Grace & others] 1241—C
  p-aminosalicylic, fatal intoxication, [Muri] 901—ab
  p-aminosalicylic, hypersensitivity to, [Kløvstad] 92—ab
  p-aminosalicylic, in pulmonary tuberculosis, complications from, [Bøyum] 92—ab
  p-aminosalicylic in tuberculosis, 80; [Domagk] 1504—ab
  p-aminosalicylic, intermittent use of streptomycin and, in pulmonary tuberculosis, [Tanner] 791—ab
  p-aminosalicylic, intravenously in pulmonary tuberculosis, [Paraf] 205—ab
  p-aminosalicylic, N.N.R., (Gold Leaf) 1141
  p-aminosalicylic, orally and streptomycin intramuscularly in pulmonary tuberculosis, [Ross] 1256—ab
  p-aminosalicylic, plus streptomycin compared with "rimifon" Switzerland, 1487
  p-aminosalicylic plus streptomycin, effect on tubercle bacilli in vitro, [Espersen] 402—ab
  p-aminosalicylic plus streptomycin for tuberculous meningitis; recovery, [Löffler] 1348—ab
  p-aminosalicylic, resistance of tubercle bacilli, [Hofmann] 714—ab
  p-aminosalicylic, side-effects, [Gundersen] 92—ab
  p-aminosalicylic sodium, parenteral use, [Roberts] 1678—ab
  p-aminosalicylic, tetany crisis during treatment, Paris, 594
  ascorbic, and penicillin, combined use, 906
  ascorbic, combined with procaine in treatment of allergy, 314
  ascorbic, in stress, 823—ab
  ascorbic—U.S.P., N.N.R., (Physicians' Drug & Supply) 444
  Cevitamic: See Acid, ascorbic
  dehydrocholic, treatment of 4 types of hemophilia, [Honorato] 975—ab
  folic, in leukemia, relation to effects of aminopterin therapy, [Swendseid] 1162—ab
  folic, metabolism, [Hausmann] 90—ab
  folinic, metabolism, [Hausmann] 90—ab
  hyaluronic, protective colloids and urolithiasis, 576—E
  hydrocyanic, poisoning, nitrite and thiosulfate therapy, [Chen & Rose] *113
  hydrocyanic, poisoning, sequels (reply) [von Oettingen] 410
  iodopanoic, name recognized by Council, 63
  iodostearic (ethyl di-iodostearate) hepatosplenography with, [Baronchelli] 1504—ab
  Isonicotinic Acid Hydrazid. See Isoniazid
  d-lysergic acid diethylamide tartrate (L S.D.), mental changes from, [DeShon] 1253—ab
  myristic, lipogenesis, 370—E
  nicotinic, effect on pulmonary circulation and hypertension, Italy, 1485
  nicotinic, in cerebral circulation disorders, [Mentha] 91—ab
  Uric: See Uric Acid
ACNE: See also Furunculosis
  pustular, chloramphenicol cream for, [Trice & Shafer] *1459
  scars, removal with sandpaper or revolving metal brush, (reply) [Monash] 1078

ADAPTATION
  diseases, conference on, May 29-June 4, 1952 at Laennec Hospital, Paris, 886
  syndrome (Selye's) identical with Reilly's phenomena, [Decourt] 1508—ab
ADDICTION: See Alcoholism, Barbiturates; Narcotics; Tea
ADDISON'S ANEMIA: See Anemia, Pernicious
ADDISON'S DISEASE
  adrenal cortex surgery effect on blood pressure in, 934—E
  due to metastatic bronchogenic carcinoma, [Fried] 187—C
  treatment, cortisone orally plus desoxycorticosterone implants, [Levy] *411
ADDRESSES: See Lectures
ADENOCARCINOMA
  metastases from left to right lung, pulmonary resection for, [Lambert] *1545
  primary, of esophagus simulating a benign lesion, [Goldman & others] *144
ADENOMA
  appendicular polypi [Martineau & others] *1548
  bronchial, or epitheliomas with altered stroma, [Delarue] 1352—ab
  gastric polyps, [Yarnis & others] (correction) 73
  Nontoxic, of Thyroid: See Goiter
  papillary, of breast, [González Warcalde] 205—ab
  Toxic, of Thyroid: See Goiter, Toxic
ADENOMYOSIS: See Endometriosis
ADENOPATHY: See Lymphatic System
ADHESIVES
  rubber adhesives in shoes, cause of dermatitis of feet, [Blank & Miller] *1371
ADIPOSITY: See Obesity
ADMINISTRATORS: See Executors
ADOLESCENCE
  Drug Addiction, (film review) 395
  epidemic of tuberculosis in high school, 8 year follow-up of students exposed, [Horton & others] *331
  hypertension in high school boys, 1681
  International Youth Center, Paris, 1666
  precocious puberty with pseudohermaphrodism; intra-abdominal tumor, [Guillain] 1070—ab
  precocious sexual development due to testicular tumor, [Newns] 898—ab
  stimulation of growth in 15 year old boy, 1430
  teen-age drug addicts arraigned in narcotic court of Chicago, [Hoffman & others] *655
ADRENALECTOMY: See Adrenals, surgery
ADRENALIN: See Epinephrine
ADRENALS: See also Addison's Disease
  Adrenocorticotropic Hormone: See Corticotropin
  atrophy, from cortisone therapy, [Fraser & others] *1542
  cancer (metastatic), Addison's disease due to, [Fried] 187—C
  cortex and radiation sickness, [Porter] 786—ab
  cortex, androgen production by, and reversal of sex, 526
  Cortex Compound E: See Cortisone
  cortex extract (aqueous), recovery in Waterhouse-Friderichsen syndrome after using, [Harvey] 1069—ab
  Cortex Hormone (Crystalline): See Desoxycorticosterone
  cortex insufficiency (chronic), cortisone orally plus desoxycorticosterone implants, [Levy] *411
  cortex, surgery, 934—E
  damage, relation to acute ulcers of upper gastrointestinal tract, [Woldman] *984
  eosinopenic response to epinephrine and corticotropin, [Dowden & Bradbury] *725; [Kark] 1413—C
  function in women with chronic epilepsy, [Costa & Bonnycastle] *1093
  hemorrhage in newborn, 315
  Hormone (Sympathetic): See Epinephrine
  hyperplasia (congenital), cortisone in; suppressive action of compound F and B, [Wilkins] 1420—ab
  hyperplasia, effects of cortisone on sexual and somatic development, [Wilkins] 1420—ab
  insufficiency, effect on circulating antibodies, [Larson] 197—ab
  insufficiency, surgery of adrenal cortex, 934—E
  medullar hyperadrenalism, medullectomy in, [Durante] 615—ab
  phenylbutazone (butazolidine) effect on pituitary-adrenal axis, [Kuzell & others] *729

ADRENALS—Continued
  precocious macrogenitosomia with pseudohermaphroditism, *[Guillain] 1070—ab*
  Surgery: See also other subheads under Adrenals
  surgery, bilateral total adrenalectomy, [Harrison] 1343—ab
  tuberculosis, hypertension associated with or due to, [Leriche] 1350—ab
  tumors, regitine test for preochromocytoma, [Gifford & others] *1628
ADRENOCORTICOTROPIC HORMONE: See Corticotropin
ADRENOLYTIC DRUGS
  caution with regard to their use, [Grimson & others] *215
  test for pheochromocytoma, [Gifford & others] *1628

Medicolegal Abstracts

ANESTHETICS
  ether; death of patient, 964
BARBITURIC ACID COMPOUNDS AND DERIVATIVES
  sodium amytal; pharmacist's sale without prescription; punitive damages, 1491
BASIC SCIENCE ACTS
  chiropractic; requirements not unreasonable, 779, 1491
  constitutionality; ambiguity and indefiniteness, 1491
  constitutionality; qualifications of board members; restrictions on, 1491
  constitutionality; unlawful delegation of legislative power, 1491
  examinations; reasonableness of, 779, 1491
CHILDBIRTH
  prenatal injury; liability for, 1673
CHIROPRACTIC
  basic science examinations; reasonableness of, 779, 1491
  "physicians"; chiropractors as, 1249
CINNAMON
  sensitivity to in relation to workmen's compensation, 1596
COSMETOLOGY
  dermatitis; hair wave lotion plus fixative in relation to allergy, 888
CRIMES
  murder; blood tests as constituting self-incrimination, 1158
DERMATITIS: See Cosmetology
ELECTROENCEPHALOGRAM
  admissibility in evidence, 965
ETHER: see Anesthetics
ETHICS
  dental; sale of practice by widow with percentage of future earning a part of purchase price, 1338
  rebates; acceptance as unethical, 191
EVIDENCE: See also Malpractice, evidence
  blood tests; as self-incrimination, 1158
  electroencephalogram; admissibility in evidence, 965
  scientific tests; blood typing; when admissible, 1158
  scientific tests; electroencephalogram, 965
  self-incrimination; blood typing in relation to, 1158
  witnesses, expert; consultant; right to testify *when non-resident, 83*
  witnesses, expert; license to practice; need for, 83
  witnesses, expert; non-resident physician; *right to testify, 83*
FOOD, DRUG AND COSMETIC ACTS
  federal; devices; Halox Therapeutic Generator, 1249
  federal; devices; labeling requirement; sales to physicians exempt, 1249
GOOD WILL
  dental practice; percentage of future earning a part of purchase price, 1338
HAIR
  cold wave lotion plus fixative causing dermatitis; allergy in relation to, 888
HOSPITALS, CHARITABLE
  burns; hot water bottle, 1337
  liability in general, 1337
  pay patient; liability to, 1337
HOSPITALS FOR PROFIT
  burns; diathermy, 83

Medicolegal Abstracts—Continued
HOSPITALS FOR PROFIT—Continued
diathermy; burns during treatment of rheumatoid arthritis, 83
nurses; negligence of; liability for, 83
private physician; negligence of; liability for, 83
HOSPITALS, GOVERNMENTAL
records: privileged communications in relation to, 602
records; right of patient's representative to inspect, 602
INJURIES
prenatal: liability for, 1673
KICKBACKS: See Rebates
MALPRACTICE
after-care; hospital patient, 964
anesthetics; ether; administration to patient with a cold, 964
anesthetics; ether; death of patient, 964
drainage tube left in patient, 1414
evidence; nonsectarian physician may testify concerning sectarian practice, when, 396
evidence; witnesses, expert; necessity for, 964
evidence; witnesses, expert; opinion testimony; consensus of medical opinion, 603
evidence; witnesses, lay; admissibility of testimony, 964
foreign bodies; drainage tubes, 1414
foreign bodies; needles, 603
operation; after-care requirements, 964
osteopaths; skill and care; standards by which judged, 396
osteopaths; thyroidectomy resulting in death, 396
roentgenograms; failure to take; foreign bodies, 603
skill and care; custom and usage in relation to, 603
skill and care; standards; doctors of medicine, 603, 964
skill and care; standards; sectarian practitioners, 396
thyroidectomy; death following operation by osteopath, 396
varicocelectomy; failure to remove drainage tube, 1414
MEDICAL PRACTICE ACTS
licenses; revocation; felony; conviction of, 1596
NURSES
hospital: liability for negligence of, 83
OPTICIANS
rebates; as "ordinary and necessary" business expense, 191
OPTOMETRY
licensure; requirements obtaining when applications filed are applicable, 1055
PHARMACY PRACTICE ACTS
prescriptions; sodium amytal sold without prescription; pharmacist's liability for punitive damages, 1491
schools; classification by private association; legislative adoption of, 192
PRENATAL INJURIES
liability for, 1673
PRIVILEGED COMMUNICATIONS
hospital records; right of patient's representative to inspect, 602
REBATES
as "ordinary and necessary" business expense, 191
public policy in relation to, 191
ROENTGENOGRAMS: See Malpractice
SCHOOLS
pharmacy; "accredited" school, definition of, 192
classification by private association; legislative adoption of, 192
SCIENTIFIC TESTS: See Evidence
SODIUM AMYTAL: see Barbituric Acid Derivatives and Compounds
TAXES
federal income; evasion as cause for revocation of medical license, 1596
federal income; rebates as "ordinary and necessary" business expense, 191
VARICOCELECTOMY: See Malpractice
WORDS AND PHRASES
"accredited" school, 192
"clinic," 602
"elementary" 779
"felony", 1596
"permanent," 1596
"physician," 1249
"self-incrimination" 1158
WORKMEN'S COMPENSATION ACTS
cinnamon; sensitivity to, 1596
dermatitis following exposure to cinnamon, 1596
disability; permanency of, 1596
ZONING LAWS
physician's office maintained in his home, 602
